was prominent on the palms and face and dramatically spared the area of the boy's feet covered by his shoes. In skin-prick tests, mugwort, chrysanthemum and dandelion sensitized 13.4, 10.0 and 8.5 % of the enrolled population, respectively, and 5.2 % of the population was cosensitized to all three pollens (Lee et al. 2007). In inhibition ELISA that used a pooled serum sample cosensitized to all three pollens, mugwort inhibited sIgE bindings to chrysanthemum, dandelion and mugwort up to 95, 86 and 96 %, respectively. The mugwort sIgE of this pooled serum was suppressed up to 74 and 27 % by chrysanthemum and dandelion, respectively. Chrysanthemum and dandelion were frequently cosensitized with mugwort in the general population with respiratory allergic diseases. These two species also showed extensive cross-allergenicity with mugwort.

Safety Issues

Dandelion is a commonly available food with a long history of human use and as such poses little risk or harm (Yarnell and Abascal 2009). Consumption of diets containing 33 % dandelion for months produced no toxic effects in rats (Hirono et al. 1978). The German Commission E approves the use of dandelion as a diuretic and also for use in anorexia, dyspepsia and biliary abnormalities (Blumenthal et al. 1998). Dandelion extracts are listed on the US Food and Drug Administration's 'generally recognized as safe' (GRAS) list for foods and supplements (US FDA 2012).

According to European Medicines Agency (2009) Assessment report on *Taraxacum officinale* radix cum herba, their uses for the relief of symptoms related to mild digestive disorders such as feeling of abdominal fullness, flatulence and slow digestion and for diuresis stimulation have long been recognized empirically and are plausible on the basis of bibliography and pharmacological data, although there are no data available from clinical studies. The diuretic action of preparations from *Taraxaci radix cum herba* may be associated with the high kalium

content and with certain flavonoids, although no studies confirm this hypothesis. Bitter principles (sesquiterpenoids) may be responsible for the stimulation of digestive fluids in stomach and bile flow stimulation. Reliable data on acute toxicity are only available for whole crude drug and some extracts. Oral administration of preparations from *Taraxaci radix cum herba* can be regarded as safe at traditionally used doses with the exception of patients with renal failure and/or diabetes and/or heart failure. Further, in the documentation of the traditional medicinal use within the European Union, no serious adverse effects have been reported; however, clinical safety data on extracts of *Taraxaci radix cum herba* is still lacking. Due to lack of data, *Taraxaci radix cum herba* preparations cannot be recommended for children and adolescents below the age of 12 years, in pregnancy and lactation, and must not be used in case of individuals with obstructions of bile ducts, cholangitis, liver diseases, gallstones, active peptic ulcer and any other biliary diseases. Hypersensitivity to the Asteraceae sesquiterpene lactones or other active substances from *Taraxaci radix cum herba* is also regarded as contraindication.

Traditional Medicinal Uses

Dandelion has been known since ancient times for its therapeutic properties in Chinese, Arabian and native American traditional medicine and has been utilized for the treatment of various ailments such as dyspepsia, heartburn, spleen and liver complaints, hepatitis and anorexia (Grieve 1971; Chiej 1984; Bown 1995; Schütz et al. 2006a, b; Yarnell and Abascal 2009). It is still used in modern phytotherapy in Europe, Asia and the Americas (Clare et al. 2009). Dandelions have long been used in herbal medicine for their choleric, diuretic, antiinflammatory, appetite-stimulating and laxative properties (Hagymási et al. 2000; Clare et al. 2009). All parts of the plant, but especially the root, are slightly aperient, cholagogue, depurative, strongly diuretic, hepatic, antipyretic, detoxicant, galactagogue, laxative, stomachic and tonic (Grieve 1971; Chiej

1984; Lust 1974; Bown 1995; Foster and Duke 1998). The root is also experimentally cholagogue, hypoglycaemic, and a weak antibiotic against yeast infections (Foster and Duke 1998). The dried root was official in the United States Pharmacopoeia. Dandelion root is a registered drug in Canada, sold principally as a diuretic. The root is primarily considered a gastrointestinal remedy supporting digestion and liver function, while the leaf is used as a diuretic and bitter digestive stimulant. A tea made from dandelion root, black horehound herb, sweet flag root and mountain flag is taken after meals for biliousness and dizziness (Grieve 1971). A tea made from dandelion root, parsley root, balm herb and liquorice roots is taken to treat gallstones. A preparation of dandelion root, polypody root, long-leaved plantain, shepherds' purse and rhubarb is taken for piles. A mixture of dandelion root, juniper berries and broom tops is taken for liver and kidney ailments.

In the olden days, dandelion juice was the favourite preparation both in official and domestic medicine (Grieve 1971). Dandelion is used as a bitter tonic in atonic dyspepsia and as a mild laxative in habitual constipation. The German Commission E Monographs, a therapeutic guide to herbal medicine, approve *Taraxacum officinale* for dyspepsia, urinary tract infections, liver and gallbladder complaints and appetite loss. It is especially effective and valuable as a diuretic because it contains high levels of potassium salts and therefore can replace the potassium that is lost from the body when diuretics are used (Bown 1995). The plant is used internally in the treatment of gall bladder and urinary disorders, gallstones, jaundice, cirrhosis, dyspepsia with constipation, oedema associated with high blood pressure and heart weakness, chronic joint and skin complaints, gout, furuncles (boils), eczema and acne (Bown 1995). The latex contained in the plant sap can be used to remove corns, warts and verrucae; to treat inflammations of the gall bladder; and to remove stones in the liver (Chiej 1984). In Derbyshire, the juice of the stalk is applied to remove warts (Grieve 1971). A tea made from the leaves is laxative. Tea prepared from *T. officinale* has been used against fever,

insomnia, jaundice, rheumatism, eczema and other skin diseases and constipation. A leaf decoction can be drunk to 'purify the blood,' for the treatment of anaemia, jaundice, and also for nervousness. Crushed leaves are applied on lesions and insect and snake bites.

Dandelion has been traditionally used in the treatment of various liver disorders in Croatia (Domitrović et al. 2010). *Taraxacum officinale* is commonly used in Jordan folk medicine for the treatment of panophthalmitis, chronic constipation and diabetes. In addition, herbalists prescribe the aqueous extract of *Taraxacum officinale* to enhance male's fertility (Tahtamouni et al. 2011). Dandelion has been used as a remedy for anaemia, purifying the blood, and providing immune modulation in Iran (Modaresi and Resalatpour 2012). In Korean herbal medicine, dandelion has been used to improve energy levels and health (Lee et al. 2012).

Other Uses

Dandelions are important foraging plants for bees; they are an important source of nectar and pollen. The milky latex has been used as a mosquito repellent. A liquid plant feed can be made from the root and leaves. Yellow or green dye colours can be obtained from the flowers and from the roots, a magenta-brown dye is obtained.

A fungitoxin, named lettucein A, isolated from the leaves exhibited fungitoxic effects on the growth of *Cladosporium herbarum* (Hanawa et al. 1995). The dandelion 2S albumins possessed inhibitory activity against phytopathogenic fungi and the oomycete *Phytophthora infestans* at micromolar concentrations with various isoforms differing in their antifungal activity (Odintsova et al. 2010).

Comments

Dandelion has become a nuisance weed in parks, roadsides, house gardens and yards in many temperate countries.

Impatiens balsamina

Scientific Name

Impatiens balsamina L.

Synonyms

Balsamina angustifolia Blume, *Balsamina balsamina* (L.) Huth (inval.), *Balsamina coccinea* DC., *Balsamina cornuta* DC., *Balsamina foeminea* Gaertn., *Balsamina hortensis* Desp., *Balsamina lacca* Medik., *Balsamina minutiflora* Span., *Balsamina mollis* G.Don, *Balsamina odorata* Buch.-Ham. ex D.Don, *Balsamina racemosa* Buch.-Ham. ex D.Don, *Impatiens arcuata* Benth., *Impatiens cornuta* L., *Impatiens eriocarpa* Launert, *Impatiens lobbiana* Turcz., *Impatiens longifolia* Wight, *Impatiens malayensis* Griff., *Impatiens rosea* Lindl., *Impatiens stapfiana* Gilg

Family

Balsaminaceae

Common/English Names

Balsam, Garden Balsam, Touch Me Not Balsam, Garden Balsam, Garden Balsamine, Impatiens, Jewelweed, Rose Balsam, Spotted Snapweed.

Vernacular Names

Bangladesh: Dopati

Burmese: Dau Dalet

Chamorro: Kamantigi

Chinese: Feng Xian Hua, Ji Xing Zi

Chuukese: Pee Cca, Pee-Cha

Dutch: Juliaantje

French: Balsamine Des Jardins, Impatience

German: Balsamine, Gartenspringkraut

India: Gulmendihi (Hindi), Dushpatrijati (Sanskrit), Kasittumbai (Siddha), Kasittumbai (Tamil), Gul Mehendi (Urdu)

Indonesian: Pacar Banyu (Javanese), Paru Inai (Minangkabau), Pacar Air

Japanese: Tsurifune-Sō

Korean: Bongseonhwa

Malaysia: Bunga Embung, Bunga Tabo, Hinai Ayam, Hinai Pacak, Inai Air, Lak Kecil, Dandalet (Sarawak)

Palauan: Hosengka

Philippines: Suranga (Bikol), Solonga, Suranga (Bisaya), Kamantigi (Iloko), Kamantig (Pampangan) Saungga (Sulu), Kamantigi (Tagalog)

Russian: Neditroga Bal'zaminovaja

Samoan: Patiale

Spanish: Balsamina, Chachupina, Chico, Madama

Swedish: Balsamin

Thai: Thian Baan, Thian Dok, Thian Suan

Tongan: Polosomo

Vietnamese: Bống Nước, Cây Bông Móng Tay; Móc Tai, Móng Tay

Origin/Distribution

This species is indigenous to southern Asia in India and mainland Southeast Asia. It is widely grown in gardens and has naturalized in disturbed areas as a common escape from cultivation in tropical and subtropical areas. It has been introduced into South China, southern Europe and Turkey.

Agroecology

Although a warm-climate species, it still can be grown outdoors after the last frost in temperate areas. In its native range, the plant is found from sea level to 1,250 m elevation in wet open areas or as forest undergrowth. It is adaptable to many soils including heavy clay soils but prefers a moist, well-drained, humus-rich soil. It grows in full sun to partial shade.

Edible Plant Parts and Uses

The flowers (Paul 2011), seeds (Kunkel 1984; Phuphathanaphong 1992; Paul 2011), leaves and young shoots (Read 1946; Heyne 1950; Kunkel 1984) have been reported to be edible. Stella Paul (2011) uses the flowers in a vegetarian 'Kofta', wherein the petals are made into little balls, dipped in a batter (chickpea powder or rice powder or corn flour), shallow fried and then cooked in a curry with sliced potatoes. She also adds petals to salad. The dried seeds are ground and a pinch added to tea. The seeds are also eaten raw or cooked and also afford an edible oil (Kunkel 1984; Phuphathanaphong 1992). In China the leaves and shoots are cooked and eaten (Read 1946; Kunkel 1984) and also in Bali (Heyne 1950).

Botany

An erect, annual herb, 20–60 (–90) cm high. The stem is glabrous or weakly pubescent when young, succulent and sparsely branched with

Plate 1 Foliage and flowers of garden balsam

swollen nodes. Leaves alternate but lower ones occasionally opposite, sessile to shortly petiolate 1–2 cm, lamina lanceolate, narrowly elliptic or oblanceolate, 4–12 × 1.5–3 cm, with a pair of sessile black glands towards base, both surfaces glabrous or sparsely pubescent and with stipitate glands, lateral veins 4–7 pairs, base cuneate, margin deeply serrated, apex acuminate (Plate 1). Flowers solitary or in fascicles of 2–3 in leaf axils, on densely pubescent, 2–3 cm across on 1–2 cm pedicels with linear bracts. Flowers white, pink or purple, red or variegated, simple or double petalous (Plate 1). Sepals 3, lateral sepals, ovate to ovate-lanceolate, sparsely ciliate; lower sepal conical pubescent, abruptly narrowed into an incurved spur 10–20 mm long. Petals 5, upper petal orbicular, apex retuse, long mucronulate; lateral four petals pairwise connate and shortly clawed. Stamens 5; filaments linear; anthers ovoid, apex obtuse. Ovary superior, fusiform, densely pubescent. Capsule 4–5 valved, broadly fusiform, 1–2 cm, densely tomentose, narrowed at both ends, explosively dehiscent. Seeds many, black-brown, subglobose, 1.5–3 mm across, tuberculate.

Nutritive/Medicinal Properties

Flower Phytochemicals

Of the genes at four loci (H, L, P, W) that determine floral pigmentation in balsam phenotypes, only L was correlated with the presence

of a flavonol which was probably myricetin (Clevenger 1958). Kaempferol was found in the petals and sepals of all types analyzed, while quercetin was limited to the sepals of these. Leucoanthocyanins were detected in both sepals and petals of the earliest bud stages, and cyanidin and delphinidin were detected from buds of all phenotypes with cyanidin generally predominating (Alston and Hagen 1958).

Klein and Hagen (1961) reported anthocyanin production in various coloured balsam flower phenotypes as follows: In pink flower phenotype, intact petal anthocyanidins (pelargonidin) and flavonols (kaempferol); cultured petal anthocyanidins (pelargonidin, cyanidin, peonidin) and flavonols (kaempferol, quercetin); and sepals anthocyanidins (pelargonidin, cyanidin, peonidin) and flavonols (kaempferol, quercetin). In red flower phenotype: intact petal anthocyanidins (pelargonidin) and flavonols (kaempferol); cultured petal anthocyanidins (pelargonidin, cyanidin) and flavonols (kaempferol, quercetin); and sepals anthocyanidins (pelargonidin, cyanidin) and flavonols (kaempferol, quercetin). In purple flower phenotype: intact petal anthocyanidins, lacking flavonols (malvidin, kaempferol, myricetin); cultured petal anthocyanidins (cyanidin) and flavonols (malvidin, kaempferol, myricetin); and sepals anthocyanidins lacking and flavonols (malvidin, kaempferol, quercetin, myricetin).

Petals of mature flowers were pigmented by *p*-coumaroyl and feruloyl esters of pelargonidin-3,5-diglucoside supplemented by highly substituted derivatives of pelargonidin and by large amounts of kaempferol as the aglycones and two glucosides, while balsam stems were found to have 3-monoglucosides of kaempferol, quercetin, pelargonidin, cyanidin and delphinidin (Hagen 1966a). Hagen (1966a) reported a progressive elaboration of anthocyanin in red balsam flower by dividing it into four developmental stages: stage I had no anthocyanin, stage 2 pelargonidin-3-monoglucoside appeared as the only anthocyanin, stage 3 with multiple pelargonidin intermediate compounds and stage 4 at anthesis many of the compounds disappeared leaving one major pigment, *p*-coumaroyl pelargonidin-3,5-diglucoside. Mansell and Hagen (1966) found that

when pelargonidin-3-monoglucoside was introduced into genetically white petals, it was converted to acylated pelargonidin-3,5-diglucoside. Miles and Hagen (1968) found that balsam flower contained enzymes that catalyzed the glycosylation of phenolic compounds. Enzymes were extracted which glycosylated hydroquinone to arbutin and at least three different flavonols to the 3-monoglucoside. It was suggested that the flavonol glycosylating enzyme acted naturally to glucosylate a precursor of both flavonols and anthocyanins to the 3-monoglucoside. The only elaboration of an anthocyanin observed with petal extracts was an acylation of pelargonidin-3-monoglucoside.

A flavonoid-3- β -D-glucosidase was purified from balsam petals of *Impatiens balsamina* (Boyle et al. 1969). When the petal preparation was incubated with pelargonidin-3-monoglucoside, hydrolysis of the glucoside was followed by a spontaneous decomposition of the aglucone nucleus. Both glucosidase and galactosidase activities were detected.

The following compounds were isolated from the flowers: kaempferol, quercetin and 1,4-naphthoquinone derivatives (Ishiguro and Oku 1997); a kaempferol 3-rhamnosyldiglucoside, isolated from white petals of and its structure determined as kaempferol-3-*O*-[2''-*O*- α -l-rhamnopyranosyl-3'' *O*- β -D-glucopyranosyl]-*P*-D-glucopyranoside (Fukumoto et al. 1994); kaempferol 3-rutinoside and 2-hydroxy-1,4-naphthoquinone (lawsone) (Oku and Ishiguro 2001); sodium 3-hydroxide-2[[sodium 3-hydroxide-1,4-dioxo(2-naphthyl)] ethyl]naphthalene-1,4-dione (impatienolate) and sodium 2-hydroxide-3-(2-hydroxyethyl)naphthalene-1,4-dione (balsaminolate) (Oku and Ishiguro 2002); kaempferol and its derivatives kaempferol-3-glucoside, kaempferol-3-glucosylrhamnoside and kaempferol-3-(*p*-coumaroyl)glucoside (Hua et al. 2001); and kaempferol and quercetin (Lim et al. 2007).

Fruit/Seed Phytochemicals

Five novel baccharane glycosides, hosenkosides A–E, were isolated from the seeds (Shoji et al. 1994a). Hosenkol A was the genin of hosenkosides

A and D, and hosenkol B was the genin of hosenkosides B and E. Hosenkol C, the genin of hosenkoside C, was determined as (3*S*,4*R*,17*R*,20*S*,24*Z*)-3,17,21,26,28-pentahydroxybacchar-24-ene. Another four rare baccharane glycosides, hosenkosides L–O, were isolated and their structures elucidated as hosenkoside L as hosenkol A 3-*O*-sambubiosyl-28-*O*-glucoside, hosenkoside M as hosenkol as 3-*O*-sambubiosyl-26-*O*-glucosyl-28-*O*-glucoside, hosenkoside N as hosenkol C 3-*O*-glucosyl-28-*O*-glucoside and hosenkoside O as hosenkol D 3-*O*-sophorosyl-28-*O*-glucoside (Shoji et al. 1994c). Another six baccharane glycosides were isolated: hosenkoside F (hosenkol 3-*O*-sambubiosido-26-*O*-glucoside), hosenkoside H (hosenkol B 3-*O*-sambubioside), hosenkoside I (hosenkol 3,26-*O*-diglucoside), hosenkoside G (hosenkol C 3-*O*-sambubiosido-28-*O*-glucoside), hosenkosides J (hosenkol A 3-*O*-sophoroside) and hosenkoside K (hosenkol 3-*O*-sophorosido-26-*O*-glucosyl-28-*O*-glucoside) (Shoji et al. 1994b).

Dinaphthofuran-7,12-dione derivatives, named balsaminones A and B, and 2-methoxy-1,4-naphthoquinone were isolated from the pericarp (Ishiguro et al. 1998). A high molecular weight protein has been isolated as a major polypeptide comprising 85 % of the total extractable proteins in balsam fruit pericarp (Pal and Biswas 1994). This protein appeared to be a homo-tetramer consisting of subunits, Mr 75 K. Four closely related highly basic, antimicrobial peptides of 20 amino acids long, containing four cysteine residues forming two intramolecular disulfide bonds, designated Ib-AMP1, Ib-AMP2, Ib-AMP3 and Ib-AMP4 (Tailor et al. 1997) and Ib-AMP1 and Ib-AMP4 peptides, were isolated from the seeds (Thevissen eYIb-AMP1, a highly basic, 20-residue peptide was found to have five arginine residues and to contain four cysteines forming two intramolecular disulfide bonds (Patel et al. 1998). Two new flavone glycosides isolated from the seeds were determined as quercetin-3-*O*-[α -l-rhamnose-(1 \rightarrow 2)- β -D-glucopyranosyl]-5-*O*- β -D-glucopyranoside and quercetin-3-*O*-[(6''-*O*-caffeoyl)- α -l-rhamnose-(1 \rightarrow 2)- β -D-glucopyranosyl]-5-*O*- β -D-glucopyranoside (Lei et al. 2010). 2-Methoxy-1,4-naphthoquinone (MeONQ)

abounds in the *I. balsamina* pod at the level of 4.39 % (w/w db) (Wang et al. 2011). Eight major baccharane glycosides, namely, hosenkosides A, B, C, F, G, K, L and M, were isolated from the seeds (Li et al. 2011).

The major fatty acids of *I. balsamina* seed oil reported included 4.7 % palmitic acid, 5.8 % stearic acid, 2.8 % arachidic acid, 18.3 % oleic acid, 9.2 % linoleic acid, 30.1 % linolenic acid and 29.1 % α -parinaric acid (9c, 11t,13t,15c-octadecatetraenoic acid) (Gunstone 1996).

Leaf Phytochemicals

2-Methoxy-1,4-naphthoquinone (Ding et al. 2008), lawsone, lawsone methyl ether and methylene-3,3'-bilawsone (Sakunphueak and Panichayupakaranant 2010b, 2012) were isolated from the leaves.

Stem Phytochemicals

Two new tetrahydronaphthalenes, 1 α , 2 α -diol-4 α -ethoxy-1, 2, 3, 4-tetrahydronaphthalene (1) and 1 α , 2 α , 4 β -triol-1, 2, 3, 4-tetrahydronaphthalene (2), were isolated from the stem (Chen et al. 2010).

Root Phytochemicals

A natural bisnaphthoquinone, methylene-3,3'-bilawsone, two naphthoquinones (lawsone and 2-methoxy-1,4-naphthoquinone), two coumarin derivatives (scopoletin and isofraxidin) and a sterol (spinasterol) were isolated from balsam roots (Panjchayupakaranant et al. 1995). A biscoumarin, 4,4'-biisofraxidin, was isolated from balsam root cultures (Panichayupakaranant et al. 1998). Different elicitors, namely, yeast extract, *Candida albicans* homogenate, *Trichophyton rubrum* homogenate, chitosan, and methyl jasmonate (MJ), depending on concentrations used exerted differential effects on the production of the three main naphthoquinones, lawsone (2-hydroxy-1,4-naphthoquinone), lawsone methyl ether and methylene-3,3'-bilawsone in balsam root cultures

(Sakunphueak and Panichayupakaranant 2010a). Treatment with MJ (400 μ M) was capable of increasing production of lawsone and lawsone methyl ether up to 8.6- and 11.3-fold higher, respectively, compared to the level in untreated cultures. Treatment of 21-day-old root cultures with 300 μ M MJ for 36 hours resulted in the production of 10.0, 0.78 and 0.23 mg/g DW of lawsone, its methyl ether and methylene-3,3'-bilawsone, respectively. Such levels were sufficient for commercial production. These compounds were found to possess various pharmacological activities that had been shown to assist with the treatment of skin diseases.

Optimization of the feeding conditions showed that adding 500 mg/l methionine to a 21-day-old balsam root cultures increased production of lawsone methyl ether and 3,3'-methylenebislawsone up to 2.6- and 3.1-fold higher, respectively, compared to the controls (Sakunphueak et al. 2013). In addition to lawsone, lawsone methyl ether and 3,3'-methylenebislawsone, various pharmacologically interesting secondary metabolites were isolated such as a flavonoid, luteolin; a naphthoquinone, 2,3-dihydroxy-1,4-naphthoquinone; and a triterpenoid, echinocystic acid.

Plant/Cell Culture Phytochemicals

2-Hydroxy-1,4-naphthoquinone was isolated from the aerial plant parts (Glennie and Bohm 1965). Shikimic acid was shown to be an excellent precursor of 2-hydroxy-1,4-naphthoquinone in *I. balsamina* aerial parts (Chen and Bohm 1966). p-Hydroxybenzoic acid was also found to be a precursor of 2-hydroxy 1,4-naphthoquinone balsam (Bohm 1967). A bisnaphthoquinone derivative named impatienol, 3-hydroxy-2-[[3-hydroxy-1,4-dioxo (2-naphthyl)] ethyl] naphthalene-1, 4-dione from aerial parts (Ishiguro et al. 2000), and 2-methoxy-naphthalene-1,4-dione were isolated from balsam plants (Jin et al. 2011). The cell culture-derived parent plants yielding high levels of 2-methoxy-1,4-naphthoquinone as initiated explants were found capable of producing two naphthoquinones, lawsone and an

unknown, which was more polar than lawsone (Panichayupakaranant 2001).

Some of the published pharmacological properties of the plant are elaborated below.

Antioxidant Activity

Studies revealed that the different balsam flower extracts exhibited antioxidant activity, with the water extract showing the strongest activity (Hu et al. 2007). The antioxidant capacity of balsam flower extract (per 100 g) was equivalent to the antioxidant capacity of vitamin C 2.3 g, quercetin 0.76 g and rutin 0.02 g, respectively. All balsam stem extracts possessed moderate antioxidant potential in the 1,1-diphenyl-2-picrylhydrazyl (DPPH) radical scavenging and reducing power assays (Su et al. 2012). The total phenolic and flavonoid contents ranged from 2.88 to 13.63 mg gallic acid equivalents/g dried extract and 0.98 to 7.87 mg quercetin equivalents/g dried extract, respectively.

Anticancer Activity

A pilot study demonstrated that ethanol or chloroform leaf extracts had in-vitro antitumour activity against the HepG2 human hepatocellular carcinoma cell line (Ding et al. 2008). The MTT assay showed that only the chloroform CHE2 fraction had a strong tumour inhibition ratio (IC_{50} =6.47 mg/l), which was superior to that of curcumin (IC_{50} =13.95 mg/l). The active component of the fraction was identified as 2-methoxy-1,4-naphthoquinone which exerted potent in-vitro antitumour activity against HepG2 cells.

2-Methoxy-1,4-naphthoquinone (MeONQ) from *Impatiens balsamina* exhibited high ability to induce gastric adenocarcinoma necrosis, showing good potential as a candidate agent for *Helicobacter pylori* infection-related disease therapy (Wang and Lin 2012). MeONQ resulted in serious necrosis via superoxide anion catastrophe when the treatment doses were higher than 50 μ M, whereas apoptosis occurred at low treatment doses (25–50 μ M) through the caspase-dependent

apoptosis pathway. Necrosis was the dominant mode of adenocarcinoma cell death.

Antimicrobial Activity

The naphthoquinone, 2-methoxy-1,4-naphthoquinone exhibited antimicrobial activity (Kang and Moon 1992). A bioactive antimicrobial compound ($LC_{50}=26$ ppm) isolated from the 95 % ethanol extract of the dried aerial parts of *Impatiens balsamina* was identified as 2-methoxy-1,4-naphthoquinone (MNQ) (Yang et al. 2001). Five Gram-positive and two Gram-negative bacteria as well as all eight fungi (including multidrug-resistant strains) tested were highly sensitive to MNQ. A tea prepared according to traditional methods was found to contain sufficient MNQ to account for its antimicrobial properties. All balsam stem extracts showed good antimicrobial activity especially antifungal activity against all of the tested microorganisms (Su et al. 2012).

A set of related antimicrobial peptides (Ib-AMPs) was isolated from *I. balsamina* seeds (Thevissen et al. 2005; Tailor et al. 1997; Patel et al. 1998). Native Ib-AMPs showed no haemolytic nor toxic activity up to a concentration of 100 μ M, demonstrating the potential of the native Ib-AMPs to combat fungal infections. Kaempferol and quercetin from balsam flowers were found to have antibacterial activity against an acne-inducing agent, *Propionibacterium acnes* (Lim et al. 2007). Minimum inhibitory concentrations (MICs) for both compounds were ≤ 32 and ≤ 64 μ g/ml for clindamycin-sensitive and clindamycin-resistant *P. acnes*, respectively. The four combination formulations (kaempferol and either erythromycin or clindamycin; quercetin and either erythromycin or clindamycin) exhibited a synergic inhibition of *P. acnes* growth. The combination of kaempferol with quercetin showed an indifferent effect. The combination of clindamycin with kaempferol or quercetin showed a greater synergic effect than that of erythromycin with kaempferol or quercetin.

All parts (root/stem/leaf, seed and pod) of *I. balsamina* extracts exhibited bactericidal activity against multiple antibiotic-resistant

Helicobacter pylori (Wang et al. 2009). Specifically, the pod extract had significantly lower MICs and MBCs (1.25–2.5 and 1.25–5.0 μ g/ml, respectively). Of the five pod-extraction solvents, both ethyl acetate and acetone were the most efficient for the anti-*H. pylori* compounds of the pod extraction. This activity exceeded that of metronidazole and approximated to that of amoxicillin. 2-Methoxy-1,4-naphthoquinone (MeONQ) and stigmasta-7,22-diene-3 β -ol (spinasterol) isolated from the pods and roots/stems/leaves of *I. balsamina*, respectively, exhibited anti-*H. pylori* (Wang et al. 2011). The minimum inhibitory concentrations (MICs) and minimum bactericidal concentrations (MBCs) for MeONQ were in the ranges of 0.156–0.625 and 0.313–0.625 μ g/ml, respectively, and in the ranges of 20–80 μ g/m both of MICs and MBCs for spinasterol against antibiotic (clarithromycin, metronidazole and levofloxacin)-resistant *Helicobacter pylori*. Notably, the potent activity of MeONQ was equivalent to that of amoxicillin (AMX) and its action was dose dependent. The ethanol and rectified spirit balsam seed extracts showed promising antibacterial activity against the growth of bacteria species *Escherichia coli* and *Bacillus anthracis*, whereas the ethanol and petroleum ether extracts showed better results against the fungal growth of *Aspergillus niger* and *Fusarium* sp. (Jain 2011).

Among the naphthoquinones isolated from balsam leaves, lawsone methyl ether showed the highest antimicrobial activity (Sakunphueak and Panichayupakaranant 2012). It showed antifungal activity against dermatophyte fungi and *Candida albicans* with the MICs and MFCs in the ranges of 3.9–23.4 and 7.8–23.4 μ g/ml, respectively, and also had some antibacterial activity against aerobic, facultative anaerobic and anaerobic bacteria with MICs in the range of 23.4–93.8, 31.2–62.5 and 125 μ g/ml, respectively. Lawsone showed only moderate antimicrobial activity against dermatophytes (MICs and MFCs in the ranges of 62.5–250 and 125–250 μ g/ml, respectively), but had low potency against aerobic bacteria, and was not active against *C. albicans* and facultative anaerobic bacteria. In contrast, methylene-3,3'-bilawsone showed significant antimicrobial activity only against *Staphylococcus*

epidermidis and *Bacillus subtilis* (MIC and MBC of 46.9 and 93.8 µg/ml, respectively).

Antianaphylactic Activity

Ethanol extract (35 %) of *I. balsamina* white petals was found to exhibit significant antianaphylactic activity in the murine immediate hypersensitivity reaction system induced by hen egg-white lysozyme (Ishiguro et al. 1992). A 35 % ethanol petal extract from *Impatiens balsamina* was found inhibitory against platelet-activating factor (PAF)-induced hypotension (Oku and Ishiguro 1999). One mechanism of the antianaphylactic effects of *Impatiens balsamina* was characterized as PAF-antagonist effects. The 35 % ethanol petal extract exhibited antianaphylactic effect by preventing hen egg-white lysozyme (HEL)-induced decrease in blood flow in mice (Ishiguro et al. 2002). Its active components, kaempferol 3-rutinoside and lawsone also significantly inhibited the decrease of blood flow. They also found that platelet-activating factor (PAF) and serotonin participated in decreasing the blood flow, but histamine did not.

Analgesic/Antiinflammatory Activities

Significant selective cyclooxygenase-2 (COX-2) inhibitory activities were observed for two new 1,4-naphthoquinone sodium salts; sodium 3-hydroxide-2[[sodium 3-hydroxide-1,4-dioxo (2-naphthyl)]ethyl]naphthalene-1,4-dione (impatienolate); and sodium 2-hydroxide-3-(2-hydroxyethyl)naphthalene-1,4-dione (balsaminolate), isolated from the corolla of *Impatiens balsamina* (Oku and Ishiguro 2002). The results supported the use of *I. balsamina* to treat articular rheumatism, pain and swelling.

WNT Signalling Inhibitory Activity

2-Methoxy-1,4-naphthoquinone from *I. balsamina* inhibited the TCF/β-catenin (TOP) transcriptional activity (IC₅₀ 2.9 µM), while it decreased the transcriptional activity of FOP (mutated TCF-binding site)-transfected cells at >5 µM.

Antipruritic/Antidermatitic Activity

A 35 % ethanol petal extract significantly inhibited the scratching behaviour induced by Dextran T40 and compound 48/in mice (Ishiguro and Oku 1997). Kaempferol, quercetin and 1,4-naphthoquinone derivatives in the extract were demonstrated to show antipruritic effects. Dinaphthofuran-7,12-dione derivatives named balsaminones A and B and 2-methoxy-1,4-naphthoquinone isolated from the pericarp exhibited significant antipruritic activity (Ishiguro et al. 1998).

The 35 % ethanol petal extract at 100 mg/kg significantly inhibited serious scratching behaviour in the NC mouse with established dermatitis when administered i.v. 1 hour before or p.o. 24 hours before the measurement (Oku and Ishiguro 2001). A 10 µg/kg dose of kaempferol 3-rutinoside and 2-hydroxy-1,4-naphthoquinone (lawsone) isolated from the extract also inhibited scratching behaviour in the dermatitis NC mouse. When 4-week-old NC mice with no symptoms were administered orally 100 mg/kg/day of IB until 13 weeks of age, protection was also noted against scratching behaviour during the development of dermatitis. The results suggested the extract to be effective for the prevention and treatment of atopic dermatitis. 2-Hydroxy-3-(2-hydroxyethyl)-1,4-naphthoquinone; ferulic acid; 2,2'-methylenebis(3-hydroxy-1,4-naphthoquinone); and 2,2'-ethylidenebis(3-hydroxy-1,4-naphthoquinone) (impatienol) all exhibited significant antipruritic activity in 48/80-induced scratching behaviour in mice (Oku et al. 2002). However, 2-methoxy-3-(2-hydroxyethyl)-1,4-naphthoquinone (balsaquinone) did not show any activity. The results indicated these compounds to be promising for treating allergic diseases with chronic and severe pruritus.

Antinociceptive Activity

Methanol balsam flower extract demonstrated strong and dose-dependent antinociceptive activity in all the chemical- and heat-induced mice models (Imam et al. 2012). The use of naloxone confirmed the association of opioid receptors in the

central antinociceptive effect. The extract also exhibited significant central nervous system depressant effect.

Antityrosinase Activity

Kaempferol isolated from the methanol balsam flower extract exhibited inhibitory activity against mushroom tyrosinase with an ID_{50} of 0.042 mM (Lim et al. 2006). Kaempferol also strongly inhibited melanin production by *Streptomyces bikiniensis*, in a dose-dependent manner, without inhibiting cell growth.

Testosterone 5-Alpha-Reductase Inhibition Activity

A bisnaphthoquinone derivative named impatiol isolated from the aerial parts exhibited significant testosterone 5-alpha-reductase inhibitory activity (Ishiguro et al. 2000). It may have potential therapeutic use in male benign prostatic hyperplasia (BPH) and lower urinary tract symptoms (LUTS).

Anthelmintic Activity

Balsam seed oil exhibited moderate anthelmintic activity against *Pheretima posthuma* in-vitro (Jalalpure et al. 2007).

Traditional Medicinal Uses

Impatiens balsamina has been used as an indigenous medicine in Asia for the treatment of rheumatism, fractures and fingernail inflammation (Wang et al. 2009). The plant is cathartic, diuretic and emetic and prescribed for treatment of pains in the joints (Chopra et al. 1986). In Korea, *Impatiens balsamina* has been used in traditional oriental medicine to treat scrofulosis, carbuncles, tuberculosis and dysentery (Kang and Moon 1992). The Korean folk medicine 'Bong Seon Wha Dae' (prepared from balsam stems) has been used to cure constipation and

acute gastritis (Park et al. 2003). In China, all parts of the plant are for all sorts of foreign bodies, e.g., metal in the throat that had been inadvertently swallowed, as well as for thorns and splinters in the flesh, and the powdered seeds are used for difficult labour (Stuart 1979). The seeds are expectorant and also used for cancer treatment.

The flowers are mucilaginous and cooling and are employed for snakebites, lumbago and intercostal neuralgia (Duke and Ayensu 1985). The flowers, and their alcoholic extract, possess marked antibiotic activity against some pathogenic fungi and bacteria (Chopra et al. 1986). Flowers of the plant are used in folk medicine to treat lumbago, neuralgia, burns and scalds in Bangladesh (Imam et al. 2012). Juice obtained from white petals is applied topically for dermatitis and urticaria (Khare 2004).

In the Philippines, the leaves are pounded and used in poultices to dissolve felons (Guerrero 1921). In Malaysia, the leaves are used for poulticing broken and torn nails (Burkill 1966). In Brunei, root decoction is administered for irregular menstruation (Khare 2004).

Other Uses

The plant is widely cultivated as a garden ornamental. The flowers are used to prepare a red dye and used as a substitute for henna (*Lawsonia inermis*) for finger and toe nails and in cosmetics. The seed oil can be used for burning lamps and in the surface-coating industry. The leaves are used for dyeing.

Comments

Garden balsam is easily propagated from seeds.

Impatiens walleriana

Scientific Name

Impatiens walleriana Hook.f.

Synonyms

Impatiens episcopi H.J. Veitch, *Impatiens giorgii* De Wild., *Impatiens holstii* Engl. & Warb., *Impatiens lujai* De Wild., *Impatiens sultanii* Hook.f.

Family

Balsaminaceae

Common/English Names

Balsam, Bizzy-Lizzie, Busy Lizzy, Garden Impatiens, Impatiens, Japanese Balsam, Jewel Weed, Patience Plant, Patient Lucy, Shady Lady, Snapweed, Sultan's Balsam, Sultan's Flower, Sultana, Touch Me Not, Zanzibar Balsam

Vernacular Names

Brazil: Beijo De Frade
Chinese: Su Dan Feng Xian Hua
Czech: Netýkavka Turecká
Dutch: Juliaantje

East Africa: Sunguala (Chagga), Matuanange (Zanzibar)

French: Balsamine Sauvage

German: Fleissiges Lieschen

India: Khujuang Lei (Manipuri)

Samoan: Patiale

Spanish: Balsamina, Chico

Swedish: Flitiga Lisa

Thai: Dtôn Tian Fà-Ràng

Tongan: Polosomo

Vietnamese: Mống Tay Suitan

Origin/Distribution

The species is native to East Africa (i.e. south-eastern Kenya, Tanzania, southern Malawi, western Mozambique and eastern Zimbabwe). The species is widely cultivated as an ornamental in many parts of the world and has also become naturalized in many of these areas.

Agroecology

In its native range and countries where it has naturalized, it is found in coastal forest areas, riverine thickets, bushland, waterway margins, damp and shady places, and in riparian habitats. It has become a weed of roadsides, disturbed sites and waste areas in populated areas. It grows best in uniformly moist, organic rich, well-drained soils in partial to full shade. It is drought and frost intolerant.

Edible Plant Parts and Uses

The flowers are edible and have a sweet taste (Anonymous 2012; Deane 2007–2012; Rop et al. 2012). They can be added to salads or mixed into fancy drinks.

Botany

A perennial or annual herb, simple or branched with succulent, translucent, green or reddish tinged, glabrous stem, slightly thickened and semi-woody at the base, 30–90 cm high. Leaves alternate, simple, glabrous broadly elliptic, or ovate to oblong-elliptic 13 cm long and 2.5–5.5 cm wide, with 5–8 pairs of lateral veins and 1–2 (sometimes more) extrafloral stipitate basal glands, apex acute or acuminate, base cuneate, margin crenate denticulate (Plates 1, 2, 3 and 4).

Plate 1 Pink flowered balsam

Plate 2 Purple flowered balsam

Flowers predominantly in pairs or threes in the axils of upper stem and branches, pedicels 2–4 cm with linear-lanceolate to subulate bracts. Lateral sepals 2, ovate-lanceolate or linear-lanceolate, green, small, 3–7 mm long. Lower sepal whitish, shallow, abruptly constricted into 2.5–4.5 cm long, curved, narrow spur. Petals 5, free, 3 cm across, various shades of pink, rose, orangey red, red, white, or variegated (Plates 1, 2, 3 and 4). Upper petal broadly obcordate or obovate and crested, lateral petals connate towards base. Ovary fusiform and glabrous. Fruit fusiform, 15–25 × 4–6 mm wide in the middle, glabrous, pale green capsule, dehiscing explosively to eject numerous small, brownish seeds.

Nutritive/Medicinal Properties

Rop et al. (2012) reported that edible flowers of *Impatiens walleriana* had a dry matter content (%w/w) of 14.75 %, crude protein of 4.60 g/kg

Plate 3 Red flowered reddish leaves balsam

Plate 4 Orange flowered green leaves balsam

and the following elements (mg/kg fresh mass (FM)): P 382.73 mg, K 2835.25 mg, Ca 405.62 mg, Mg 203.34 mg, Na 94.29 mg, Fe 7.26 mg, Mn 6.05 mg, Cu 1.31 mg, Zn 8.72 mg and Mo 0.39 mg. The flowers had total antioxidant capacity of 6.89 g ascorbic acid equivalents/kg FM, total phenolic content of 4.85 g gallic acid/kg FM and total flavonoid content of 1.93 g rutin/kg FM.

Traditional Medicinal Uses

Leaves and roots dried, pounded mixed with water, juice drank as abortifacient (Kokwaro 2009).

Other Uses

It is widely cultivated as an ornamental in masses in shady beds, borders and woodland gardens, as ground cover or edging along walks or paths in parks and gardens. It is also cultivated in containers, window boxes and hanging baskets as a house plant.

Comments

Busy Lizzie is readily propagated from seeds and stem cuttings.

Spanish: begonia alta, begonia de cera, begonia perpetua, begonia vírgin, flor de nácar, semperflorens auténtica

Origin/Distribution

The species is native to South America—Argentina, Brazil, Paraguay, Peru and Uruguay (Golding 1982; Smith et al. 1986; Golding and Wasshausen 2002) It has naturalized elsewhere in the tropics and subtropics. In Hawaii and in La Réunion, where the species has naturalized, it has become invasive in natural and seminatural environments.

Agroecology

The natural habitat of many begonias including this species consists of moist, cool forests and tropical rainforests from 0–1,000 m altitude in its native range. Elsewhere the species has naturalized in planted forests, ruderal/disturbed and urban areas. It is tolerant of hot and humid summers but is sensitive to low temperature below 12 °C, dying back in frost and resprouting from underground rootstocks in spring in subtemperate areas. It abhors water-logged conditions and is tolerant of short dry periods due to their thick and waxy leaves which help minimize water loss. The species does best in dappled shade but will grow in full sun or considerable shade but is less floriferous under the latter. Reddish-coloured or bronze-leaved varieties are more tolerant of full sun than green-leaved varieties. The species thrives best in moist, well-drained, acidic (pH 5.5–6.5) sandy loams or loamy soils rich in organic matter.

Edible Plant Parts and Uses

Begonia semperflorens (*B. cucullata*) and *Begonia elatior* have potential to be cultivated as edible flowers with an acceptable taste (Friedman et al. 2007). The fleshy leaves and flowers are edible raw or cooked and can have a slight bitter after taste (Laferriere 1990, 1992; Deane 2007–2012). Sauteed alligator meat with *Begonia* sauce represents a musty challenge to the palate. Chopped begonia petals are mixed into a food processor or mixer with soft cream cheese, strawberry, or other jelly or jam and some juice or liquid to prepare *Begonia* spread (Deane 2007–2012). In Paraguay the leaves of the *B. cucullata* are eaten fried or in soup or salads, while the sap is used to treat sore throats (Gonzfilez-Torres 1980).

Botany

A glabrous, caulescent, stoloniferous, monoeocious herb, 30–80 cm high with green or reddish succulent stems. Leaves are alternate, simple, weakly asymmetric, broadly ovate with truncate,

Plate 1 Cluster of pink *Begonia* flowers

Plate 2 Close view of pink *Begonia* flower and leaves

usually incurved base, 8–12 cm long by 6–9 cm wide, 6–7 palmately nerved, margin undulating or weakly crenate-serrate, reddish at times, glossy dark green adaxially, paler green abaxially; some varieties have bronzed, reddish, or variegated leaves (Plates 1, 2 and 3). Stipules oblong, 1.5–3 by 1.5–2.5 cm, persistent. Flowers are either staminate (male) or pistillate (female) occurring in few-flowered axillary cymes on 3–5 cm long peduncles, bracts, ovate and serrulate. Male flowers with four white, red, or pink tepals in decussate arrangement, outer tepals sub-orbicular 10–15 mm across, inner ones smaller and narrowly obovate 10–12 mm long by 6–8 mm wide, stamens yellow, free, numerous, filaments short, anthers linear. Female flowers 4–5; obovate tepals; white, red, or pink, styles 3; bifid; the stigmatic tissue linear; spiral; continuous; ovary inferior with three fused carpels; placentae bilamellate (Plates 1, 2, 3 and 4). Fruit a dehiscent capsule, unequally 3-winged, the largest deltoid. Seeds tiny and acute.

Nutritive/Medicinal Properties

Seed Phytochemicals

The major storage substances in the tiny seed of *Begonia semperflorens* were found to be lipids sequestered in lipid vesicles and proteins in the form of protein crystalloids and electron-dense globoid crystals in protein bodies (West and Lott 1991). The globoid crystals contained high Mg, K and P levels characteristically found in phytin from large-sized seeds. Small traces of Ca were found in globoid crystals within protein bodies found in the provascular tissue of the embryo.

Flower Phytochemicals and Antioxidant Activity

Six anthocyanins, cyanidin 3-*O*-(2"-xylosyl,6"-*trans* caffeoyl)-glucoside, *cis* and *trans* isomers

of cyanidin 3-*O*-(2"-xylosyl,6"-*p*-coumaroyl)-glucoside and cyanidin 3-*O*-(2"-glucosyl,6"-*p*-coumaroyl)-glucoside were isolated from flowers of different horticultural *Begonia* (Chirol and Jay 1995).

Growing of *B. semperflorens* in a greenhouse was found to improve the flower yield as compared to netting house, but long-day treatment did not enhance further the yield in both growth habitats (Friedman et al. 2007). These results indicated *B. semperflorens* to be indifferent to long day, but *B. elatior* was highly sensitive. The antioxidant levels of closed and open flowers of *B. semperflorens* were not reduced during storage. However, the level of anthocyanins was reduced especially in the closed flowers. Antioxidant activity of opened *B. semperflorens* 'Imperial Red' flowers was determined as 11.1 μ M Trolox equivalent/g DW, the anthocyanin content of the flower was 0.37 O.D./520 g DW and its acid content was 1.58 % citric acid equivalent. Antioxidant activity of closed flowers was 21.1 μ M Trolox Equivalent/g DW, its anthocyanin content 0.35 O.D./520 g DW and its acid content 1.90 % citric acid equivalent.

Leaf Phytochemicals and Antioxidant Activity

Begonia cucullata was reported to contain 4.8 meq oxalate per gram dry weight, representing 96 % of the total acidity present in plant sap (Tavant and Mange 1965).

The maximum quantum yield of PSII (Fv/Fm [photosystem II (Maximal fluorescence-minimal fluorescence/maximal fluorescence)] in red leaves (cv. Cocktail) was significantly higher than that in green leaves (cv. Super Olympia) during and after high-light stress (Zhang et al. 2010). High light also induced significant increases in anthocyanins in both genotypes. Before light stress exposure, red-leaved plants showed an average anthocyanin content 9.5-fold higher than that of 'Super Olympia' green-leaved plants. In contrast, high light induced a dramatic increase in anthocyanin content in 'Cocktail' plants, and anthocyanin content was 14-fold

higher in 'Cocktail' than in 'Super Olympia'. In red-leaved 'Cocktail' anthocyanin content increased from 55.1 U/g FW before light stress exposure to 290.4 U/g FW after 3-day light stress exposure. In green-leaved 'Super Olympia', anthocyanin content increased from 5.3 U/g FW before to 18.9 U/g FW after 3-day light stress exposure. After high-light stress, anthocyanins in 'Super Olympia' reverted to the initial level, whereas 'Cocktail' leaves retained most of their accumulated anthocyanins. The two genotypes had similar chlorophyll and carotenoid content before and after exposure to high light, whereas chlorophyll and carotenoids were lower in 'Cocktail' during exposure to high-light stress. The Chl a/b ratio of 'Cocktail' was not significantly different from that of 'Super Olympia' throughout the experiment, suggesting that there was no difference in light-harvesting capacity between the two genotypes.

There were no significant differences in flavonoid or phenolics content between the two genotypes either before or after high-light stress (Zhang et al. 2010). However, 'Cocktail' contained more flavonoids and phenolics than 'Super Olympia' under high-light stress. In red-leaved 'Cocktail', from zero-day light stress exposure to after 3-day light stress exposure, flavonoids increased from 3.06 mg/g FW to 8.66 mg/g and phenolics increased from 0.88 to 2.59 mg/g FW, respectively, while in green-leaved 'Super Olympia', flavonoids increased from 3.46 mg/g FW to 6.94 mg/g and phenolics increased from 1.0 to 1.93 mg/g FW, respectively.

High-light stress enhanced the pool size of the xanthophyll cycle (violaxanthin (v)+antheraxanthin (A)+zeaxanthin (Z)) in green-leaved plants, whereas no significant change in pool size was observed in red-leaved plants (Zhang et al. 2010). However, high light increased the de-epoxidation state of the xanthophylls cycle $[(A+Z)/(V+A+Z)]$ in both cultivars.

Under high-light stress, DPPH antioxidant activity increased dramatically in 'Cocktail', which was maintained at a high level even after recovery (Zhang et al. 2010). However, DPPH antioxidant activity in 'Super Olympia' exhibited

no obvious changes, and its level remained low throughout the experiment. The activities of superoxide dismutase and peroxidase were induced to similar level in both genotypes, while the activities of catalase, dehydroascorbate reductase and ascorbate peroxidase (APX) were significantly higher in 'Super Olympia' during light stress. After recovery, antioxidant enzyme activities gradually declined in both genotypes, despite the increased APX activity in 'Super Olympia'. The results indicated that 'Cocktail' had greater nonenzymatic antioxidant capacity, but lower overall enzymatic antioxidant activities in response to high-light stress. Overall, the results suggested that anthocyanins primarily functioned as photoprotective light filters rather than as antioxidant molecules during high-light stress in *B. semperflorens* and that red-leaved varieties afforded greater photoprotection than green-leaved varieties.

Traditional Medicinal Uses

B. cucullata has been reported to have analgesic, antiinflammatory, antimalarial, febrifuge, vulnerary and diuretic properties and used as herbal medicine for diarrhoea, dysentery, fever, inflammations, hiccups, malaria, sore throat, stomatosis, thirst, warts, wounds, toothache and pharyngosis (Duke et al. 2009). The macerated plant is employed for fever, hiccup and thirst by the Guarani. Paraguayans apply mashed roots to toothache, apply juice on warts and moles, apply leaves on inflammation and wounds and charred plant parts on sores in mouth and throat. Most species have oxalic acid.

Other Uses

Wax begonia with single or double flowers in shades of white, pink, or red plus bicolour versions and green, reddish, or variegated foliage is an extremely popular garden annual grown for mass planting in beds, container, or baskets.

Comments

The plant is readily propagated from seeds, leaf and stem cuttings and root division. The rhizomes (thickened rootstock), tubers, and roots are poisonous.

Begonia x tuberhybrida

Scientific Name

Begonia x tuberhybrida Voss

Synonyms

Begonia × *tuberhybrida* var. *grandiflora* Voss, Begonia Tuberhybrida Group, *Begonia tuberosa* hort

Family

Begoniaceae

Common/English Names

Hybrid Tuberous Begonia, Tuberous Begonia

Vernacular Names

French: Bégonia Tubéreux

German: Knollenbegonie

Spanish: Begonia Tuberosa

Swedish: Knölbegonia

Origin/Distribution

Begonia tuberhybrida is a complex group of cultivars developed from hybridization of several Andean species such as *B. boliviensis* with pink

flowers or *B. pearcei* with yellow flowers (Dewitte et al. 2011; USDA, ARS 2012). Other parental Andean species used in hybridization include *Begonia veitchii* and *B. davisii*. Tuberous begonias are cultivated and not found wild.

Agroecology

Tuberous begonias thrive best in a mild cool summer climate and are totally intolerant of high temperatures or very high humidity levels or frost. The ideal conditions for tuberous begonias are areas where evening temperatures do not fall below 15 °C and where day temperatures are less than 27 °C (on average). They grow best in partial to dappled shade, in well-drained fertile loamy-acidic soil rich in humus. The plants need frequent watering and fertilization and need protection from strong winds. Container plants may be brought indoors in fall and grown as winter houseplants.

Edible Plant Parts and Uses

The fleshy leaves and flowers are edible (Laferriere 1990, 1992; Deane 2007–2012) raw or cooked and used in salads (Deane 2007–2012). Chopped begonia petals are mixed into a food processor or mixer with soft cream cheese, strawberry or other jelly or jam and some juice or liquid to prepare Begonia spread. The brightly coloured flowers have a delicious light, lemon taste and a crisp texture (Anonymous 2012).

Snipped petals are used as a garnish in salads and sandwiches or whole petals dipped in flavoured yogurt and serve as an appetizer.

Botany

A large heterogeneous Begonia group with tuberous roots, complex and diversified because of crossing and backcrossing. Plants are small annual/perennial, tuberous herb growing to 30–45 cm high in a compact bushy habit with thick tuberous roots. Leaves alternate, 5–10 cm long, cordate to ovate with undulating or dentate margin, glossy green simple with lobed margin and pinnate venation with succulent green or reddish petioles (Plate 1). Flowers in few-flowered axillary cymes. Flower with male and female flowers on the same plant. Flowers small 1.5–2 cm

Plate 1 Leaves and flowers

to large, 5–7 cm, showy, waxy, roselike, single (4–5 tepals) or double flowers with multiples whorls of tepals of variable brightly colours of red, pink, purple, orange, yellow with ruffled-toothed or smooth margins (Plates 1 and 2).

Nutritive/Medicinal Value

Six anthocyanins, cyanidin 3-*O*-(2''-xylosyl,6''-trans caffeoyl)-glucoside, *cis* and *trans* isomers of cyanidin 3-*O*-(2''-xylosyl,6''p-coumaroyl)-glucoside and cyanidin 3-*O*-(2''-glucosyl,6''-p-coumaroyl)-glucoside were isolated from flowers of different horticultural *Begonia* (Chirol and Jay 1995).

Studies showed that the content of chlorophyll a, chlorophyll b and carotene increased with 10, 40 and 50 Gy ⁶⁰Co-γ ray irradiation of *B. tuberhybrida* flowers (Ding et al. 2004). However, the content of chlorophyll a and carotene increased more with 50 Gy and chlorophyll b content increased more with 40 Gy. Co-γ ray irradiation of *Begonia tuberhybrida* improved SOD, CAT activities at higher dosages (40, 50 Gy). Higher dose increased malondialdehyde (MDA) content. Irradiation also increased the flavonoid, and the 20 and 10 Gy irradiation gave better effects.

Cucurbitane triterpenes: cucurbitacin B (Doskotch et al. 1968, 1969; Doskotch and Hufford 1970), cucurbitacin D, dihydrocucurbitacin B and very small quantities of a degraded cucurbitacin compound and hexanor-cucurbitacin D were isolated from *B. tuberhybrida* tubers (Doskotch and Hufford 1970). Cucurbitacin B

Plate 2 (a) and (b) Mass planting of different coloured tuberose Begonia

was found to have antitumour activity against human nasopharynx carcinoma (KB cells) in-vitro (Doskotch et al. 1968, 1969).

B. tuberhybrida was reported to have a crassulacean acid metabolism (CAM) and to contain with oxalic acid as the predominant acid, followed by malic, citric, and succinic acids, and phorbic acid was present in small amounts (Nordal and Resser 1966).

Other Uses

Begonia x tuberhybrida is a very popular and attractive ornamental plant for pots, baskets, containers or window boxes, flower beds, borders and houseplant.

Comments

Hybrids are arranged into 13 different groups based upon the floral structure and habit (Perry 2012):

- (S) Single—large single flowers with flat tepals
- (S-Fr)—large single flowers, tepal margins frilled or ruffled
- (S-Cr)—large single flowers, frilled or tufted centre of tepals
- (D-N)—large, double flowers, like *Narcissus*, central tepals forming a trumpet
- (D-C)—large, double flowers, like *camellia*, unruffled edge
- (D-CR)—large, double flowers, like *camellia*, ruffled edge
- (D-R)—large double flowers with rose bud-like centre
- (D-Car)—large double carnation-like flowers, tepals fringed on margins
- (D-P)—large usually double flowers like *camellias*, picotee, tepals with different colours on margin blending with other colours
- (D-M)—like picotee only distinct non-blending line of colour on margins
- (D-Mar)—like *camellia* but rose coloured, blotched or spotted with white
- (S-D-HB)—single or double pendant flowers with trailing/cascading stems, hanging basket
- (S-D-Mul)—bushy compact multiflora, with single and double flowers

Origin/Distribution

African Tulip Tree is native of West and Central Africa and western East Africa: Angola, Ethiopia, Democratic Republic of Congo, Ghana, Kenya, Sudan, Tanzania, Uganda and Zambia. It is planted as an ornamental elsewhere in Africa, e.g. in Cape Verde, Zimbabwe and Madagascar. African Tulip Tree is widely grown in tropical and subtropical regions outside Africa. It has become naturalized and is an important component of secondary vegetation, e.g. in Mexico and Puerto Rico, and is considered a weed in Guam and Hawaii.

Agroecology

In its native range in Africa, the species occurs naturally in secondary forests in the high forest zone; in riverine forests; in deciduous, transition and savannah forests from sea level to 2,000 m altitude; and in areas receiving 1,300–2,000 mm annual precipitation and with mean annual temperatures of 27–30 °C. The biggest trees grow in moist, sheltered ravines. The species thrives in full sun and is frost and shade intolerant. It prefers rich, moist, well-drained loamy, sandy soils but will grow in poor infertile soils including clayey soils and limerock. It is adaptable in soils of a wide pH range of 4.5–8.

Edible Plant Parts and Uses

In Thailand the flowers are eaten (Wetwitayaklung et al. 2008). Young leaves used in soups by Igbo in Nigeria (Okeke et al. 2009). The seeds are also eaten in many parts of Africa.

Botany

A medium-sized deciduous perennial tree, reaching a height of 10–25 (–35 m), with a round, compact crown of dense, dark-green foliage, with stout, buttressed trunk, thick lenticellate branches;

Plate 1 African Tulip flowers

Plate 2 Imparipinnate leaves

young bark pale, grey-brown and smooth turning grey-black, scaly and fissured vertically and horizontally with age. Leaves opposite, exstipulate and imparipinnate (Plates 1 and 2). Each leaf comprising 5–7 pairs of opposite leaflets and a terminal one, petioles 7–15 cm long. Leaflet elliptical to ovate or ovate-oblong, (3–)7–16 cm by (1.5–)3–7 cm, entire margin, base asymmetrically truncate to cuneate, apex acuminate or acute, glabrous to pubescent below, with (6–)8–11 pairs of lateral veins, dark green adaxially and light green abaxially, on 5 mm long petiolule. Inflorescence a terminal corymb-like raceme. Flowers hermaphrodite, zygomorphic, large and showy; pedicel up to 6 cm long; calyx spathaceous, 4–8 cm long, recurved, long-acuminate, ribbed, tomentellous, green, splitting at anthesis; corolla widely campanulate from a contracted base, 8–15 cm long, 5-lobed, lobes obtuse with strongly crisped margins, scarlet or orange-red with yellow margin and throat; stamens 4 with

yellow filaments, inserted on corolla tube, didynamous, more or less exerted, anthers linear, dark brown; ovary superior, 2-celled, style filiform, yellow, slender, stigma 2-lamellate, reddish (Plate 1). Fruit a narrowly ellipsoidal woody capsule 15–27 cm by 3.5–7 cm, blackish-brown, dehiscing by two valves, many-seeded. Seeds thin and flat, 1.5 cm by 2 cm, very broadly winged.

Nutritive/Medicinal Properties

Flower/Fruit Phytochemicals

The following phytochemicals were obtained from the petroleum ether extracts of the flowers: hexadecanoic acid, methyl ester (13.42 %), tricosane (9.64 %), n-heneicosane (13.57 %), bis(2-ethylhexyl) phthalate (22.50 %), 1,2-benzenedicarboxylic acid, oleic acid (19.58 %), diisooctyl ester (14.71 %) and levodopa (18.49 %) (Zaheer et al. 2011). From the methanol extract of the flowers, the following compounds were identified: 4,8-methanoazulen-9-ol, decahydro-2,24,8-tetramethyl-, stereoisomer (77.31 %) and thujopsene (22.69 %). The flowers also contained verminoside and specioside and the fruits caffeic acid and ajugol (Elusiyan et al. 2011). The flowers were also found to contain phenols and flavonoids (Wetwitayaklung et al. 2008; Hareesh et al. 2010) and anthocyanins (Banerjee and De 2001). Four compounds were identified from the flowers: butane 1, 1-diethoxy-3-methyl- (35.11 %) and n-hexadecanoic acid (30.22 %), 1,2-benzenedicarboxylic acid, diisooctyl ester (21.78 %) and oleic acid (12.89 %) (Kumaresan et al. 2011).

Leaf Nutrients and Phytochemicals

The nutrient composition of the young leaves (ulumiri) used as vegetables had been analysed by the Federal University of Technology, Akure, and the University of Nigeria as follows per 100 g edible portion: moisture 44 g, energy 212 kcal, protein 8.6 g, fat 0.3 g, carbohydrate 43.7 g, fibre

0.1 g, ash 2.6 g, vitamin A 28 µg RE, thiamin 1.3 mg, riboflavin 0.30 mg, niacin 1.12 mg, folic acid 44 µg, vitamin C 17.64 mg, Ca 13 mg, P 600 mg, Fe 9.7 mg and Zn 4.2 mg (CINE 2007).

Caffeic acid was isolated from the leaves (Subramanian et al. 1973). Spathodol, a new polyhydroxysterol with the structure (24S)-5 α -stigmasta-7,25-diene-2 α ,3 β -diol plus triterpenoids β -sitosterol, 3 β -acetoxyoleanolic acid; siarasinolic acid; 3 β -acetoxy-12-hydroxyoleanan-28, 13-olide; oleanolic acid and β -sitosterol-3-*O*- β -D-glycopyranoside were isolated from the dried leaves of *S. campanulata* (Ngouela et al. 1991). Phenolic compounds, namely, *p*-hydroxybenzoic acid and iridoid glucoside, were isolated from the leaves (El-Hela 2001a, b). Three new iridoids determined as 6-*O*-*trans*-caffeoyl-decinnamoyl globularimin, 6-*O*-*trans*-caffeoyl-asystasioside E and 6-*O*-*trans*-caffeoyl-5,7-bisdeoxycynanchoside and provisionally named as spatheosides A, B and C, respectively, were isolated from *S. campanulata* leaves (Gouda 2009). Also isolated were four known iridoids identified as verminoside, 6'-*O*-*trans*-caffeoyl-loganic acid, catalpol and ajugol. Leaves were reported to contain tannins, saponins, anthraquinone glycosides and flavonoids (Ilodigwe et al. 2010a, b). Elusiyan et al. (2011) reported the leaves to contain verminoside, kaempferol diglucoside, caffeic acid and phytol. Akharaiyi et al. (2012) reported the leaves to contain alkaloids, flavonoids, saponins, phenols, steroids and terpenoids.

The chloroform/ethyl acetate fraction of the alcoholic extract of *Spathodea campanulata* aerial parts afforded the isolation of phenolic acids, caffeic acid and ferulic acid; the fraction ethyl acetate/methanol on further fractionation afforded three flavonoids: kaempferol 3-*O*-glucoside, quercetin 3-methyl ether and 8-methoxy kaempferol 3-*O*-glucoside (Nazif 2007). The predominant components of the cuticular wax of *S. campanulata* leaves were n-alcohols (35 %), with octacosanol and triacontanol as the most abundant ones (Gormann et al. 2004). Other notable constituents were sterols, albeit present in trace amounts.

Stem/Root Phytochemicals

A pentacyclic triterpenoid acid, spathodic acid, with the structure $3\beta,19\alpha,24$ -trihydroxyolean-12-ene-28-oic acid, and the sitosterol-3-*O*- β -D-glucopyranoside were isolated from the stem bark of *S. campanulata* (Ngouela et al. 1990). Three antimalarial principles were isolated from the stem bark: 3β -hydroxyurs-12-en-28-oic acid (ursolic acid) and two of its derivatives, 3β -hydroxyurs-12,19-dien-28-oic acid (tomentosolic acid) and $3\beta,20\beta$ -dihydroxyurs-12-en-28-oic acid (Amusan et al. 1996). Spathoside, a new cerebroside, was isolated from *Spathodea campanulata* stem bark, besides known compounds (n-alkanes, linear aliphatic alcohols, sitosterol and their esters, β -sitosterol-3-*O*- β -D-glucopyranoside, oleanolic acid, pomolic acid, *p*-hydroxybenzoic acid and phenylethanol esters) (Mbosso et al. 2008). The stem bark was also found to contain verminoside and ajugol (Elusiyan et al. 2011), flavonoids, terpenoids and phenols (Ngouela et al. 1988).

The stem bark of *S. campanulata* used as a drug in traditional medicine was found to contain the following nutraceutical (mg/kg): carbohydrates 1.36 mg, protein 0.32 mg, fats 0.03 mg and energy 5.69 kcal/g; and phytoconstituents (mg/kg), alkaloids 1.92 mg, flavonoids 2.50 mg, tannin 0.35 mg, lignin 0.29 mg, glycosides 0.05 mg, serpentines 0.05 mg, terpenoids 0.03 mg and saponins 0.01 mg and 0.12 mg (Brindha et al. 2012). The bark also contained the following elements: organic carbon 1.82 %, nitrogen 1.12 %, phosphorus 0.36 %, potassium 3.89 %, sodium 0.18 %, calcium 3.25 %, magnesium 2.56 %, sulphur 0.32 %, zinc 1.02 ppm, copper 0.11 ppm, iron 56.23 ppm, manganese 5.36 ppm, boron 0.08 ppm and molybdenum 0.03 ppm.

An iridoid glucoside, ajugol, and two phenolic derivatives (*p*-hydroxy-benzoic acid and methyl *p*-hydroxybenzoate) were isolated from the root bark (Pianaro et al. 2007).

Antioxidant Activity

The flower had a low TEAC (Trolox Equivalent Antioxidant Capacity) value of 0.07 and an IC_{50}

value of 157.72 μ g (Wetwitayaklung et al. 2008). The total polyphenol content in the flowers was 2.38 g/100 g dried flower and 6.38 g/100 g in the methanol crude flower extract. Recent studies by Hareesh et al. (2010) showed that *S. campanulata* flowers exhibited good free radical scavenging activity. At 500 μ g/ml concentration, the ethanol flower extract exhibited about 82 % of lipid peroxidation inhibition and the IC_{50} value for the flower extract was 201 μ g/ml. In the hydroxyl radical activity using the deoxyribose method, 500 μ g/ml of the extract showed about 84 % inhibition and the IC_{50} value was 200 μ g/ml. In the DPPH radical inhibition activity, the flower extract showed around 68 % at 500 μ g/ml concentration and the IC_{50} value was 225 μ g/ml.

Ethanol extract of *Spathodea campanulata* leaves showed significant dose-dependent antioxidant activity in-vitro (Kowti et al. 2010a). The extract showed an effective free radical scavenging activity towards the nitric oxide and superoxide radicals with IC_{50} values of 160 and 198 μ g/ml, respectively. Total antioxidant capacity at 50 and 500 μ g/ml of *Spathodea campanulata* extract was equivalent to 29.2 and 199.4 μ g/ml of α -tocopherol. At 500 μ g/ml, in nitric oxide radical and superoxide radical scavenging assay, it elicited maximum inhibition of 81 and 79 %, respectively.

The methanol extracts of *Commelina diffusa* herb and *Spathodea campanulata* bark reduced the peroxidation of bovine brain extract with an IC_{50} value of 1.39 and 0.24 mg/ml, respectively (Mensah et al. 2006). In addition the extracts also exhibited significant antioxidant activity by protecting MRC-5 cells from hydrogen peroxide-induced oxidant injury at concentrations between 1 and 10 μ g/ml. The extracts showed no inhibition of NF-kappaB at 100 μ g/ml.

Alcoholic extract of *Spathodea campanulata* aerial parts and two of the isolated fractions showed strong antioxidant activity (92, 94 and 89 % RSA, radical scavenging activity) (Nazif 2007). The antioxidant principles isolated from the various parts of *Spathodea campanulata* plant included verminoside (leaf, stem bark and flowers; EC_{50} =2.04 μ g/ml), specioside

(flowers; $EC_{50} = 17.44 \mu\text{g/ml}$), kaempferol diglucoside (leaf; $EC_{50} = 8.87 \mu\text{g/ml}$) and caffeic acid (leaf and fruits) (Elusiyan et al. 2011). The non-antioxidant components isolated in the study included ajugol (stem bark and fruits) and phytol (leaf).

Wound/Burn Healing

Topical applications of methanol *S. campanulata* bark extract ointment (2, 10 and 49 %) dose dependently decreased the score damage of the burn site in rats (Sy et al. 2005). Treatment with 10 and 49 % of the bark ointment reduced the score damage from 5 to 1 and 5 to 0.2, respectively, at day 15 after experimental burn. The bark ointment (10 and 49 %) induced a complete burn healing on the 19–20th post-burn day. The results supported the rational use of the *S. campanulata* barks in traditional medicine to promote burn healing.

For *Spathodea campanulata*, *Hoslundia opposita* and *Pycnanthus angolensis*, which were reported by the healers to be used also for wound healing, in the case of stomach ulcers, strong anti-adhesive activity against *Helicobacter pylori*, was demonstrated, while the extracts did not exhibit any direct cytotoxicity against the bacterium (Agyare et al. 2009).

Antimicrobial Activity

The methanol extracts of *Commelina diffusa* herb and *Spathodea campanulata* bark showed some level of antimicrobial activity with *C. diffusa* exhibiting selective antifungal activity against *Trichophyton* species (Mensah et al. 2006) and also antioxidant activity. Methanol extracts of *Tridax procumbens* and *Spathodea campanulata* showed significant activity against bovine mastitis bacterial pathogens coagulase-positive *Staphylococcus aureus* (8.0) and *Streptococcus agalactiae* (7.6), respectively (Das et al. 2009). The crude *S. campanulata* methanol extract was found to contain saponins, steroids, terpenoids, flavonoids, alkaloids and tannins.

The petroleum ether extract of *S. campanulata* leaf showed good inhibitory activity against *Klebsiella pneumoniae* and compared with standard antibiotic streptomycin (Dhanabalan et al. 2008). The methanol extract also showed inhibitory activity. Ethanol flower extract inhibited the in-vitro growth of *Proteus vulgaris*, *Escherichia coli* and *Klebsiella pneumonia* but was less effective against *Staphylococcus aureus* and *Salmonella typhimurium* (Kowti et al. 2010b). The flower extract showed greater potency than the leaf extract. In another study, the crude ethanol extract of *S. campanulata* leaf potently inhibited growth of nine clinical bacteria isolates, namely, *Pseudomonas aeruginosa* (wound), *Serratia marcescens*, *Escherichia coli* (urine), *Staphylococcus aureus* (wound), *Klebsiella pneumoniae* (urine), *Bacillus cereus* (wound), *Proteus mirabilis* (faeces), *Salmonella typhi* (faeces) and *Enterococcus faecium* (faeces) (Akharaiyi et al. 2012). This was followed by the methanol extract and the petroleum ether extract was least inhibitory. The crude ethanol leaf extract contained alkaloids 1.5 %, flavonoids 0.56 mg/ml QE (quercetin equivalent), saponins (3.92 mg/ml), phenols 0.04 mg/ml TAE (tannic acid equivalent), steroids and terpenoids.

Two phenolic derivatives *p*-hydroxybenzoic acid and methyl *p*-hydroxybenzoate isolated from the roots exhibited antifungal activity against the fungus *Cladosporium herbarum* (Pianaro et al. 2007). Spathoside, a new cerebroside, and known compounds (n-alkanes, linear aliphatic alcohols, sitosterol and their esters, β -sitosterol-3-*O*- β -D-glucopyranoside, oleanolic acid, pomolic acid, *p*-hydroxybenzoic acid and phenylethanol esters) isolated from *Spathodea campanulata* stem bark, inhibited significantly the growth of some Gram-positive and Gram-negative bacteria (Mbosso et al. 2008).

Four topical products prepared by incorporating the methanol extract of *S. campanulata* stem bark (20 % w/w) into aqueous cream, soft paraffin, emulsifying ointment and simple ointment bases were evaluated for their in-vitro antimicrobial efficacy (Ofori-Kwakye et al. 2009). The methanol and ethanol extracts showed good activity while the aqueous and petroleum ether extracts

exhibited little activity. The methanol extract showed the best antibacterial activity. The MIC of the methanol extract was *Candida albicans* (45–50 mg/ml), *Bacillus subtilis* and *Escherichia coli* (50–55 mg/ml), *Pseudomonas aeruginosa* (60–65 mg/ml) and *Staphylococcus aureus* (145–150 mg/ml). Antimicrobial activity of *S. campanulata* in the topical bases was in the order: aqueous cream > emulsifying ointment > simple ointment > white soft paraffin. Antimicrobial activity of *S. campanulata* in aqueous cream decreased upon storage at room temperature for 6 months. The antifungal activity of the methanol extract of *S. campanulata* was reduced upon storage, while antibacterial activity was largely unaffected. Excision wounds infected with *Staphylococcus aureus* in Sprague–Dawley rats when treated with 20 % w/w *Spathodea campanulata* stem bark cream, and Cicatrin(®) cream showed a rapid and comparable decrease in wound size (Ofori-Kwakye et al. 2011). In uninfected wounds, both 20 % w/w *Spathodea* cream and Cicatrin(®) cream application resulted in ~95 % wound closure seen on day 20 and a complete closure seen on day 24. In infected wounds, both 20 % w/w *Spathodea* cream and Cicatrin(®) cream administration led to ~91 % wound closure on day 24 and a complete wound contraction on day 28. The results supported the folkloric use of *S. campanulata* stem bark in wound healing treatment.

Anticonvulsant Activity

Spathodea campanulata leaf extract exhibited anticonvulsant activity (Ilodigwe et al. 2010a). Administration of ethanol leaf extract (250–1,000 mg/kg, p.o.) 30 minutes prior to intraperitoneal administration of pentylenetetrazole (70 mg/kg) or picrotoxin (5 mg/kg) protected the treated mice against the respective pentylenetetrazole- and picrotoxin-induced convulsion in a dose-dependent manner, offering 100 % protection at the maximum dose of 1,000 mg/kg. The extract increased the threshold of maximum electroshock and reduced duration of convulsive episodes, dose dependently. Oral administration

of *S. campanulata* ethanol extract did not significantly affect other centrally coordinated behaviours and convulsion-related properties such as position sense, righting reflex, rotarod performance, phenobarbital sleep time, and amphetamine-induced stereotypy in treated animals. The results also showed *S. campanulata* extract was nonsedative, had no antipsychotic properties, and may not affect motor coordination when used as an anticonvulsant.

Antimalarial Activity

The alcoholic extract of *Spathodea campanulata* leaves exhibited antiplasmodial activity (Markinde et al. 1987). Schizontocidal activity of the plant extract in mice blood was determined on both the early and established infections of *Plasmodium berghei berghei*. The plant extract was more effective in treating the early infection than the established one. The study provided scientific data for the use of the aqueous alcoholic decoction of the leaves of *Spathodea campanulata* for the treatment of malaria. The hexane and chloroform extracts of *S. campanulata* stem bark showed blood schizontocidal action in both the 4-day test and Rane test against *berghei berghei* in mice (Markinde et al. 1988). The chloroform extract demonstrated some prophylactic properties while the aqueous extract did not show any significant antimalarial property. Three antimalarial principles isolated from the stem bark, namely, 3 β -hydroxyurs-12-en-28-oic acid (ursolic acid) and two of its derivatives; 3 β -hydroxyurs-12,19-dien-28-oic acid (tomentosolic acid) and 3 β ,20 β -dihydroxyurs-12-en-28-oic acid suppressed parasitaemia and prolonged survival times of mice infected with *Plasmodium berghei berghei* (Amusan et al. 1996).

Larvicidal Activity

Spathodea campanulata extract exhibited larvicidal activity at 100 ppm against the mosquito *Aedes fluviatilis*, a vector of Rift Valley fever (Consoli et al. 1988). *S. campanulata*

extract had a repulsive effect on female mosquitoes at 100 ppm but at 1 ppm was attractive to females (Consoli et al. 1989). In recent studies, *Spathodea campanulata* extracts were found to have larvicidal and mosquito repellency activity against the malarial vector *Anopheles stephensi* (Aarthi and Murugan 2010). The extracts of *Spathodea campanulata* were found most effective with LC50 value of 1.343, 1.607, 1.981, 2.165 and 2.432 of larval stages I, II, III, IV and pupa, respectively. The smoke toxicity was more effective against *Anopheles stephensi*. Smoke-exposed gravid females oviposited fewer eggs when compared to those that were not exposed.

Nephroprotective Activity

Pretreatment of Wistar albino rats with the ethanol extract of *Spathodea campanulata* bark orally was found to ameliorate the effects of gentamicin on lipid peroxide formation and showed a decrease in serum marker enzymes blood urea nitrogen and serum creatinine (Shanmukha et al. 2010). It also prevented depletion of tissue-reduced glutathione levels. The histopathological studies of the kidney revealed a protective role of the extract in gentamicin-treated rats. The results indicated that the pretreatment with ethanol extract of *Spathodea campanulata* bark may be useful in preventing the damage induced by gentamicin in rat kidneys. Similar nephroprotective effects was observed against paracetamol-induced nephrotoxicity when the 70 % ethanol bark extract was orally administered to Wistar albino rats (Siddiq et al. 2012).

Hypoglycaemic Activity

Spathodea campanulata stem bark decoction exhibited hypoglycaemic activity in Streptozocin-induced diabetic mice (Niyonzima et al. 1990). The decoction decreased blood glucose in glucose tolerance test but no effect was observed on insulin levels. In another paper they reported that

the most polar fraction of the stem bark decoction exerted by far the most prominent hypoglycaemic, anticomplement, and anti-HIV activities (Niyonzima et al. 1999).

Analgesic and Antiinflammatory Activities

The ethanol leaf extract of *Spathodea campanulata*, (250–1,000 mg/kg) significantly and dose dependently prolonged the pain reaction times in hot-plate and tail-flick pain models and reduced acetic acid-induced writhing in rats (Ilodigwe and Akah 2009). The extract demonstrated significant antiinflammatory activity against acute inflammation induced by carrageenan in rats. The estimated LD50 of the extract was 4,500 mg/kg. Phytochemical analysis revealed the presence of tannins, saponins, anthraquinone glycosides, and flavonoids. The findings indicated that the leaf extract of *Spathodea campanulata* had both analgesic and antiinflammatory properties and could be beneficial in alleviating painful inflammatory conditions.

Antidiarrhoeal Activity

The antidiarrhoeal activity of *Spathodea campanulata* stem bark extracts was observed in three experimentally induced diarrhoea models, i.e. castor oil-induced diarrhoea, prostaglandin E2 (PG-E2)-induced enteropooling in rats, and charcoal meal test in mice (Rajesh et al. 2009). In castor oil-induced model, both aqueous and alcoholic extracts showed significant dose-dependent reduction of cumulative wet faecal mass. In PG-E2-induced enteropooling model, both extracts inhibited PG-E2-induced secretions. Similarly in charcoal meal test both extracts decreased the movement of charcoal indicating its antimotility activity. It was observed that the aqueous extract had more potent antidiarrhoeal activity than the alcoholic extract. Acute toxicity studies revealed that both the extracts were safe up to 2,000 mg/kg.

Photoprotective Activity

Methanol extract of macerated flowers showed maximum absorbance of UV at 200–240 nm, with good absorbance at 240–325 nm. Moderate absorbance was noted at 310–340 nm (Patil et al. 2009). The results showed that the flower extract had UV absorption ability and has potential as an antisolar agent.

Molluscicidal Activity

The aqueous (macerated and boiled), hexanic, and ethylic extracts of *S. campanulata* was found to be effective in-vitro against *Biomphalaria glabrata* in Brazil (Mendes et al. 1990). Of four plant species, *S. campanulata* was the least effective of all extracts tested against *Bulinus africanus*, the schistosomiasis (bilharzia) vector, although its methanol extract was molluscicidal (Amusan et al. 1995; Bosch 2002).

Toxicity Studies

The acute and subchronic toxicities of ethanol leaf extract of *Spathodea campanulata* was investigated by Ilodigwe et al. (2010b). For the acute toxicity study, 1,000–5,000 mg/kg of the ethanol leaf extract were administered to rats, and obvious toxic symptoms and mortality 24 hours post-administration of the extract were determined. In the subchronic study, 750–3,000 mg/kg of the extract were administered daily for 90 days; food and water consumption and body weight changes, as well as haematological and biochemical parameters, were determined periodically. The estimated LD₅₀ of the extract was 4466.84 mg/kg. There was no mortality during the period of study, but the animals showed signs of anorexia, weakness, sluggishness and significant reduction in food and water intake and body weight. The effects on haemoglobin concentration, PCV (packed cell volume), RBC (red blood cells), and WBC (white blood cells) counts were nonsignificant. The extract caused significant increases in serum liver enzymes, aspartate transaminase

(AST), alkaline phosphatase (ALP), and alanine transaminase (ALT). These changes showed recovery after 28 days post-treatment.

Traditional Medicinal Uses

Spathodea campanulata has many medicinal uses both in its native range and in areas introduced (Bosch 2002). Extracts of root, bark, leaves, and flowers are used to treat malaria, HIV, diabetes mellitus, oedema, dysentery, constipation, gastrointestinal disorders, ulcers, skin diseases, wounds, fever, urethral inflammation, liver complaints, and used as a poison antidote. *S. campanulata* has astringent properties and is widely used by traditional medicine practitioners as a relief for painful inflammatory conditions (Dalziel 1955; Oliver 1960). In Ivory Coast and Burkina Faso, various decoctions of the bark are used for herpes, impetigo, mycosis, and enema; and in combination with *Cola nitida* fruit or *Aspilia rudis*, it is used to treat Guinea worm infestations (Kerharo and Bouquet 1950). In Togo, decoctions of the bark stem and branches are used for wounds and menses problems (Adjanohoun et al. 1986). In Benin, the decoctions of the stem leaves and bark of underground parts are used for wounds, stomatitis, enteritis, and ulcers (Adjanohoun et al. 1989), and leaf sap is used for baby (Adjanohoun et al. 1988). In the Democratic Republic of Congo, powder of leaves, stem barks, and roots of *Spathodea campanulata* are used for asthma treatment (Disengomoka and Delaveau 1983; Kasonia et al. 1993) and bronchitis (Nyakabwa and Dibaluka 1990). In Yaounde region, Cameroon, fresh bark decoction is used to wash wounds (Tsabang et al. 2001). In Bulamogi, Uganda, a root decoction is used for diarrhoea and flowers and leaves are used in a wash for the body (Tabuti et al. 2003). *S. campanulata* is used in traditional African herbal medicine for the treatment of ulcers, filaria, gonorrhoea, diarrhoea, and fever (Sy et al. 2005). *Commelina diffusa* and *Spathodea campanulata* are used as wound healing agents in Ashanti traditional medicine in Ghana (Mensah et al. 2006). *S. campanulata* was also known in

Cameroon traditional medicine to have a healing activity in burn wounds. *Spathodea campanulata* was one of three plants used by traditional healers for wound healing of stomach ulcers in Bosomtwi-Atwima-Kwanwoma area, Ghana, and decoctions of the leaves and stem bark are used for wounds, skin rashes, and haemorrhoids (Agyare et al. 2009). In Ghana, decoction of the stem and root is used for paludism (Asase and Oppong-Mensah 2009). In Kenya, an infusion of the sap is used to treat colds in children by the Nandi people (Jeruto et al. 2008). *Spathodea campanulata* is popularly used for the treatment of epilepsy in Nigeria (Ilodigwe et al. 2010b).

Other Uses

African Tulip Tree is planted as an ornamental, as wayside tree, and shade tree. It is used for soil improvement, reforestation, erosion control and land rehabilitation, and as a live fence. Its dense crown does not allow intercropping, but its leaves make a useful mulch. It has been used as a shade tree in coffee plantations. In Singapore, the timber has been reported to be used for making paper. In West Africa, the wood is used to make drums and blacksmith's bellows. The bark, flowers, and leaves are also used in traditional medicine in its native home range (Tan 2001).

The wood is dirty white, very light, soft and fibrous and susceptible to fungal rots. In West Africa, the wood is used for carving but is deemed inferior for other purposes. In Ethiopia, it is used as firewood and to produce charcoal. It is a poor timber and firewood species, although occasionally used as such. The wood is difficult to burn and so the tree can be used in fire-resistant landscaping. In the Philippines, the tree is used for plywood purposes. The flower buds contain a reddish fluid and are used as water pistols by children.

Comments

African Tulip has become an invasive species in the natural ecosystem in Hawaii, Fiji, Guam, Vanuatu, the Cook Islands and Samoa and also poses a potential invader in several other tropical locations.

Agroecology

Cauliflower requires a cool, moist subtemperate climate, average daily temperatures of 15–20 °C; if temperatures go too high, the plants will not produce flower heads; if too low the plants might button, resulting in small heads. It is cold tolerant but will not survive severe frosts. It thrives best in full sun in well-drained, moist, fertile soil with significant organic matter and a pH of 6–7. As with all Brassicas, seeds germinate best with a soil temperature of around 25 °C.

Origin/Distribution

The primary area of cultivation is in the eastern Mediterranean region; from there it spreads to western and Central Europe before spreading globally, even to tropical countries where it is cultivated in the cooler mountain areas above 1,000 m.

Cauliflower and broccoli are believed to have evolved in Roman times from wild or primitive cultivated forms of *Brassica oleracea* in the eastern Mediterranean region; from there it spreads to western and Central Europe before spreading globally, even to tropical countries where it is cultivated in the cooler mountain areas above 1,000 m. During the last 400 years, white-headed cauliflower spread from Italy to central and northern Europe, which became secondary centres of diversity for annual and biennial types. Cauliflower adapted to hot and humid tropical climates has evolved in India during the last 200 years from biennial cauliflower of mainly British and Central European origin.

The leading cauliflower- and broccoli-producing countries in terms of total production (tonnes) are China 9,030,990, India 6,745,000,

Edible Plant Parts and Uses

Flowering head (curds) is edible. Cauliflower can be roasted, boiled, fried, steamed or eaten raw. When cooking, the outer leaves and thick stalks are removed, leaving only the florets. The florets should be broken into similar-sized pieces so they are cooked evenly. Cauliflower is often served with a cheese sauce, as in the dish cauliflower cheese, or with a meat gravy. Cauliflower stalks are fermented to produce ‘achar tandal’ in India. The leaves are also edible but are most often discarded. Low carbohydrate dieters can use cauliflower as a reasonable substitute for potatoes and is often used to produce a potato substitute known as ‘fauxtato’. Cauliflower is available as quick-frozen vegetables and processed in dried mixtures of soup vegetables.

Botany

An herbaceous annual with elongated cylindrical, non-fleshy stem base and growing to a height of 50–80 cm and higher to 150 cm when flowering.

Plate 1 Cauliflower leaves and curd

Plate 3 Harvested cauliflower curds

Plate 2 Harvested cauliflowers packaged for transport in an Indonesian market

Plate 4 A purple cauliflower curd

Basal and lower cauline leaves green, few to several, widely spaced, not grouped into a head, enclosing the compact terminal flowering head called the curd (Plate 1). The leaves are oblong-ovate, light greenish-grey, often simple and no lateral buds developed in the leaf axils. The curd consists of a dome of proliferated floral meristems white to cream or yellow (or purple in cultivars) on numerous fleshy peduncles (Plates 1, 2, 3 and 4). The curd is usually compact, sometimes loose, flattish or globose in shape. Bolting plants have several flower stalks. Inflorescence a raceme, 40–70 cm long with 4 merous bisexual flowers with green sepals, spatulate, yellow petals, 6 stamens—2 short and 4 long and superior ovary. Fruit a silique, 5–10 cm by 0.5 cm with 10–30 globose brown seeds.

Nutritive/Medicinal Properties

Inflorescence/Leaf Nutrients and Phytochemicals

The proximate value per 100 g edible portion of raw cauliflower was reported as follows: water 92.07 g, energy 25 kcal (105kJ), protein 1.92g, total lipid 0.28g, ash 0.76g, carbohydrate 4.97g, total dietary fibre 2.0 g, total sugars 1.91g, glucose 0.94g, fructose 0.97 g; minerals, Ca 22 mg, Fe, 0.42 mg, Mg 15 mg, P, 44 mg, K 299 mg, Na 30 mg, Zn 0.27 mg, Cu 0.039 mg, Mn 0.155 mg, F 1 µg, Se 0.6 µg; vitamin C 48.2 mg, thiamine, 0.050 mg, riboflavin 0.060 mg, niacin 0.507 mg,

pantothenic acid 0.667 mg, vitamin B-6 0.184 mg, total folate 57 µg, total choline 44.3 mg, vitamin A 13 IU, vitamin E (α-tocopherol) 0.08 mg, γ-tocopherol 0.2 mg, vitamin K (phylloquinone) 15.5 µg; total saturated fatty acids 0.064 g, 15:0 (pentadecanoic acid) 0.001 g, 16:0 (palmitic acid) 0.046 g, 17:0 (margaric acid) 0.001 g, 18:0 (stearic acid) 0.004 g, 20:0 (arachidic acid) 0.002 g, 22:0 (behenic acid) 0.001 g, 24:0 (lignoceric acid) 0.001 g, total monounsaturated fatty acids 0.017 g, 14:1 (myristoleic acid) 0.001 g, 16:1c (palmitoleic acid *cis*) 0.002 g, 18:1c (oleic acid *cis*) 0.014 g, 24:1c (nervonic acid) 0.001 g; and total polyunsaturated fatty acids 0.015 g, 18:2 n-6 c,c (linoleic acid) 0.006 g, 18:2 CLAs 0.002 g, 18:3 n-3 c,c,c (ALA, α-linolenic acid) 0.007 g, phytosterols 18 mg, tryptophan 0.020 g, threonine 0.076 g, isoleucine 0.071 g, leucine 0.106 g, lysine 0.217 g, methionine 0.020 g, cystine 0.020 g, phenylalanine 0.065 g, valine 0.125 g, arginine 0.086 g, histidine 0.056 g, alanine 0.116 g, aspartic acid 0.177 g, glutamic acid 0.257 g, glycine 0.071 g, proline 0.071 g, serine 0.086 g and lutein+zeaxanthin 1 µg (USDA 2012).

During period of cauliflower floral induction (2 weeks under 16 hours of light at 5 °C), there was a significant increase in sugar and starch content compared to that in vegetative plants grown at 20–26 °C (Sadik and Ozbun 1968). Sugar and starch content did not increase and flowering was prevented when light and CO₂ were excluded during growth at 5 °C. A 3-day dark period at 20 °C or a high temperature treatment at 33 °C with light following growth at 5 °C reduced the carbohydrate level and prevented flowering.

Brassica plants (e.g. broccoli and cauliflower) contain substantial quantities of isothiocyanates (mostly in the form of their glucosinolate precursors) some of which (e.g. sulforaphane or 4-methylsulfinylbutyl isothiocyanate) are very potent inducers of phase two enzymes (Fahey et al. 1997). Three-day-old sprouts of cultivars of certain crucifers including broccoli and cauliflower were found to contain 10–100 times higher levels of glucoraphanin (the glucosinolate of sulforaphane) than do the corresponding mature plants. Sicilian cultivars of cauliflower

possessing coloured curds displayed a high content of glucosinolates, glucoraphanin in particular, compared to white curd commercial cultivars; also some wild species had a high content of other glucosinolates (Branca et al. 2002). The glucosinolate content of 27 European cauliflower was similar to the American cauliflower cultivars but contained low amount of 2-hydroxy-3-butenyl-glucosinolate which was absent in the latter varieties (Sones et al. 1984). The major glucosinolates in European cauliflowers were identified as prop-2-enyl-glucosinolate, 3-methylsulphinyl propyl-glucosinolate, 3-indolylmethyl-glucosinolate and 1-methoxy-3-indolylmethyl-glucosinolate. Smaller amounts of but-3-enyl-glucosinolate, 2-hydroxybut-3-enyl-glucosinolate, 3-methylthiopropyl-glucosinolate, 4-methylthiobutyl-, 2-phenylethyl-glucosinolate, pent-4-enyl-glucosinolate, 2-hydroxypent-4-enyl-glucosinolate and 5-methylthiopentyl-glucosinolate were also found in some cultivars. Allyl-glucosinolate, 3-(methylthio)propyl-glucosinolate, 3-(methylsulfinyl)propyl-glucosinolate and 3-indolylmethyl-glucosinolate were present in all five American cultivars of cauliflower curd and were the major glucosinolates in their seeds as well (Carlson et al. 1987). Other glucosinolates present included 4-(methylsulfinyl)butyl-glucosinolate, 4-(methylthio)butyl-glucosinolate, 3-butenyl-glucosinolate, 4-pentyl-glucosinolate and 2-phenyl-ethyl-glucosinolate. Glucosinolates found in cauliflower purchased from local Singapore markets were in nmol/g wet weight: glucoraphanin NQ (not quantified), gluconasturtiin NQ, sinigrin 132 nmol, glucobrassicin 2,850 nmol, 4-hydroxy glucobrassicin 75.8 nmol, 4-methoxy glucobrassicin 231 nmol, 1-methoxy glucobrassicin 743 nmol, glucoiberin NQ, progoitrin (or epiprogoitrin) NQ, glucoalyssin 14.1 nmol, gluconapoleiferin NQ, gluconapin NQ, glucobrassicinapin NQ, glucoerucin NQ, 7-methylthioethyl NQ, 8-methylthioethyl NQ, total glucosinolates 4,190 nmol and glucobrassicins 93.2 % of total glucosinolates (Hecht et al. 2004). Glucobrassicins (glucobrassicin, 1-methoxyglucobrassicin, 4-methoxyglucobrassicin and 4-hydroxyglucobrassicin), precursors to indole-3-carbinols, were the predominant glucosinolates

in seven of the nine vegetables (including cauliflower and broccoli) studied, accounting for 70.0–93.2 % of all glucosinolates.

The following phenolic compounds and glucosinolates were identified in cauliflower: four sinapic acid derivatives (1,2-disinapoyl-diglucoside; 1-sinapoyl-2-feruloyl-diglucoside; 1,2,2'-trisinapoyl-diglucoside; and 1,2'-disinapoyl-feruloyl-diglucoside), three flavonoids (quercetin-3-diglucoside-7-glucoside; kaempferol-3-diglucoside-7-glucoside; and kaempferol-3-diglucoside-7-diglucoside) and six glucosinolates namely 5-methylsulfinylpentyl glucosinolate (glucoalysin); n-hexyl/methylpentyl glucosinolate (n-hexyl/methylpentyl-3-methylthiopropyl (glucoiberin); 3-indolylmethyl glucosinolate (glucobrassicin); N-methoxy-3-indolylmethyl glucosinolate (neoglucobrassicin); 4-hydroxy-3-indolylmethyl glucosinolate (4-hydroxyglucobrassicin); and 4-methoxy-3-indolylmethyl glucosinolate (4-methoxyglucobrassicin)) (Gratacós-Cubarsí et al. 2010). The main hydroxycinnamic acids (sinapic, ferulic, *p*-coumaric and caffeic acids) were isolated from cauliflower by capillary zone electrophoresis (Lee et al. 2011).

The following phenolic compounds were found in cauliflower: quercetin derivatives (quercetin -3-*O*-sophoroside-7-*O*-glucoside and quercetin -3-*O*-(sinapoyl)-sophoroside-7-*O*-glucoside), kaempferol derivatives (kaempferol-3-*O*-sophorotrioside-7-*O*-sophoroside; kaempferol-3-*O*-sophorotrioside-7-*O*-glucoside; kaempferol-3-*O*-sophorotrioside-7-*O*-diglucoside; kaempferol-3-*O*-sophoroside-7-*O*-glucoside; kaempferol-7-*O*-glucoside; kaempferol -3-*O*-(caffeoyl)sophoroside-7-*O*-glucoside; kaempferol-3-*O*-(sinapoyl)-sophoroside-7-*O*-glucoside; and kaempferol-3-*O*-(*p*-coumaroyl)-sophoroside-7-*O*-glucoside) and hydroxycinnamic acids namely 3-caffeoylquinic acid); 1,2-disinapoylgentiobiose; 1-sinapoyl-2-feruloylgentiobiose; 1,2,2'-trisinapoylgentiobiose; and 1,2'-disinapoyl-2-feruloylgentiobiose (Cartea et al. 2011). Eight minor glucosinolates, namely, 1-methylpropyl-glucosinolate, 2-methylpropyl-glucosinolate, 2-methylbutyl-glucosinolate, 3-methylbutyl-glucosinolate, n-pentyl-glucosinolate, 3-methylpentyl-glucosinolate, 4-methylpentyl-

glucosinolate and n-hexyl-glucosinolate were identified in crude sample extracts of cauliflower, broccoli and rocket salad (Lelario et al. 2012). The occurrence of these glucosinolates belonging to the saturated aliphatic side chain families C4, C5 and C6, presumably formed by chain elongation of leucine, homoleucine and dihomoleucine as primary amino acid precursors, was described. Isothiocyanate content in cauliflower juice treated by freezing, pasteurization, and high pressure was found to range from 0.79 to 25.92, 2.80 to 16.15, and 1.04 to 10.92 $\mu\text{mol/l}$, respectively (Totušek et al. 2011). Sulforaphane content in cauliflower juice treated by freezing, pasteurization, and high pressure was found to range from 0.66 to 1.61, 0.69 to 0.98 and 0.64 to 1.29 $\mu\text{g/ml}$, respectively.

No differences in free sugar (glucose, sucrose and fructose) or glucosinolate profiles in cauliflower were found between air and controlled atmosphere (3 % O_2 and 5 % CO_2 at 0 °C) (Hodges et al. 2006) storage treatments. However, the glucosinolates gluconapin (3-butenyl glucosinolate) and glucobrassicin (3-indolylmethyl glucosinolate) increased for each treatment during storage, albeit later in controlled atmosphere storage. Glucobrassicin was the major glucosinolate component, and the dramatic increase in the concentrations of this compound was reflected in increased total glucosinolate levels of air-stored cauliflower on day 28 of storage. Levels of the other glucosinolates (sinigrin (2-propenyl glucosinolate), progoitrin (2-hydroxy-3-butenyl glucosinolate), epiprogoitrin, 4-OH-glucobrassicin and 4-MeOH-glucobrassicin, as well as an unidentified glucosinolate) did not change during storage; glucoiberin content decreased after day 28. Increases in levels of gluconapin and glucobrassicin may be related to metabolic changes associated with natural and/or stress-induced senescence.

Brassica vegetables including cauliflower contain phytochemicals including glucoraphanin, the precursor of sulforaphane (SFN) and glucobrassicin, the precursor of indole-3-carbinol (I3C) and ascorbigen (ABG) (Wagner et al. 2010). Glucobrassicin was found to be enzymatically hydrolyzed to indole-3-carbinol, which in turn

reacted with L-ascorbic acid to yield ascorbigen (Wagner and Rimbach 2009). The degradation of glucobrassicin was induced by plant tissue disruption. The formation of ascorbigen was dependent on pH and temperature. The degradation of ascorbigen in acidic medium released L-ascorbic acid and a formation of methylidenindolenine; in more alkaline medium, the degradation of ascorbigen yielded 1-deoxy-1-(3-indolyl)- α -L-sorbofuranose and 1-deoxy-1-(3-indolyl)- α -L-tagatofuranose.

A total of 28 compounds were identified in cauliflower agroindustrial by-products; of these, 22 were produced naturally by the plant (Llorach et al. 2003b). The main compounds found were kaempferol 3-diglucoside-7-glucoside and its combinations with different hydroxycinnamic acids. The new products isolated were identified as kaempferol 3-diglucoside-7-diglucoside, kaempferol 3-triglucoside-7-diglucoside, kaempferol 3-feruloyldiglucoside-7-diglucoside, kaempferol 3-sinapoyltriglucoside-7-glucoside, kaempferol 3-disinapoyltriglucoside-7-glucoside, kaempferol 3-sinapoyltriglucoside-7-diglucoside and kaempferol 3-disinapoyltriglucoside-7-diglucoside.

Three indole compounds indole-3-acetonitrile, indole-3-carbinol (I3C) and 3,3'-diindolylmethane (DIM) were identified from three cruciferous vegetables, Brussels sprouts, cabbage and cauliflower (Loub et al. 1975; Wattenberg 1975). Four known (isalexin, S-(+)-spirobrassinin, 1-methoxybrassinin, brassicanal C) and three new (caulilexins A–C) phytoalexins were isolated from cauliflower florets under abiotic (UV light) elicitation, and the first synthesis of brassicanal C was reported (Pedras et al. 2006).

Six organoselenium compounds including selenium analogues of known myrosinase-derived *Brassica* volatiles 4-(methylseleno)butanenitrile, 5-(methylseleno)pentanenitrile, 3-(methylseleno)propylisothiocyanate, 4-(methylseleno)butylisothiocyanate and 5-(methylseleno)pentylisothiocyanate were identified in the pentane/ether extracts of broccoli and cauliflower florets and roots of forage rape, all obtained from plants treated with sodium selenate (Matich et al. 2012). LC–MS analysis of ethanol extracts identified

three selenoglucosinolates: 3-(methylseleno)propylglucosinolate (glucoselenoiberberin), 4-(methylseleno)butylglucosinolate (glucoselenoerucin) and 5-(methylseleno)pentylglucosinolate (glucoselenoberteroin).

Serine *trans*-hydroxymethylase, purified 46-fold from cauliflower, was found to be specific to serine (Mazelis and Liu 1967). Polyguanylate polymerase and polyadenylate polymerase were detected in the DNA-dependent RNA polymerase I fraction from cauliflower; poly(G) and poly(A) formed in-vitro by the enzyme fraction had chain length of 25–28 and 84–89 nucleotides (Mizuochi and Fukasawa 1976). Two distinct DNA polymerases, A and B, with molecular weights of 78,000 and 50,000, respectively, were isolated from a rapidly growing apical tissue of cauliflower inflorescence (Fukasawa et al. 1980). Polymerase-A bore strong resemblance to polymerase- α from mammalian cells in all properties examined, while polymerase-B was quite similar to polymerase- β of mammalian cells. An ATP-independent DNA topoisomerase with molecular weight of 54,000 was isolated from chloroplasts of cauliflower leaves (Fukata et al. 1991). Cauliflower chloroplast topoisomerase could relax positive supercoils as well as negative supercoils. From these properties, cauliflower chloroplast topoisomerase could be classified as a eukaryotic type I DNA topoisomerase.

A protein with structure-specific endonuclease activity and a molecular mass of 40 kDa was purified from cauliflower inflorescence (Kimura et al. 1997). A DNA polymerase purified from cauliflower inflorescence-designated cauliflower polymerase 1 was found to be a monopeptide with a molecular mass of 100 kDa (Seto et al. 1998). The enzyme was clearly different from cauliflower mitochondrial polymerase. Tonoplast intrinsic proteins of molecular mass 23–29 kDa were detected in the meristematic tissues of cauliflower (Barrieu et al. 1998). Appreciable differences in the degree of methyl-esterification (ME) of pectic polysaccharides were detected in cauliflower stem (Femenia et al. 1998). About 65 % of galacturonic acid (GalpA) residues were methyl esterified in floret tissues. Relative ME

showed a basipetal decrease, from 94 % in the upper stem to 51 % in the lower stem vascular tissues. The decrease was not related to a basipetal increase in glucuronic acid (GlcA) residues. An acyl-CoA oxidase and a second protein of the plant nucleotide pyrophosphatase family purified from cauliflower inhibited both glutamine synthetase (GS) and nitrate reductase (Moorhead et al. 2003). S-methyl methanethiosulfonate, an antimutagenic compound, was isolated from cauliflower (Nakamura et al. 1993).

Cauliflower was found to accumulate dehydrin-like proteins with molecular weight of 10–100 kDa in the leaf and inflorescence mitochondria during some abiotic (cold) stress (Rurek 2010). A peroxidase, a primer antioxidant enzyme, with molecular weight 44 kDa was purified with 19.3-fold and 0.2 % efficiency from cauliflower buds (Köksal and Gülçin 2008).

Upon treatment with norflurazon, both cauliflower wild type and Or gene calli synthesized significant amounts of phytoene (Li et al. 2006). Phytoene was accumulated at comparable levels, and no major differences in carotenogenic gene expression were observed between the wild-type and Or calli, suggesting Or-induced β -carotene accumulation did not result from an increased capacity of carotenoid biosynthesis.

Studies showed significant differences among broccoli and cauliflower cultivar groups for the glucosinolate proportions as well as the contents of health-promoting and flavour-influencing alkyl, alkenyl and indole glucosinolates (Schonhof et al. 2004). These differences impacted on differences in sensory properties colour, taste properties such as bitter and sweet, flavour such as green/grassy, spicy, broccoli-like, cabbage-like, cauliflower-like, kohlrabi-like, leek-like and mouth-feel pungent. Consumers were seen to prefer cultivars with a bright colour, a lower level of bitter tasting glucosinolates (alkenyl and indole glucosinolates) and a higher sucrose content. Studies showed that neoglucobrassicin and sinigrin were responsible for the bitterness of cooked cauliflower (Engel et al. 2002). Allyl isothiocyanate (AITC), dimethyl trisulphide (DMTS), dimethyl sulphide (DMS) and methanethiol (MT) were the key odorants

of cooked cauliflower ‘sulphur’ odours. They concluded that AITC, DMTS, DMS, MT, sinigrin and neoglucobrassicin were the potential physicochemical determinants of cooked cauliflower acceptance.

Cauliflower and red cabbage showed differences in their anthocyanin profiles: cyanidin-3,5-diglucoside was absent in cauliflower, while it was well represented in red cabbage, together with the characteristic anthocyanin of *Brassica* genus, cyanidin-3-sophoroside-5-glucoside (Scalzo et al. 2008). The *p*-coumaroyl and feruloyl esterified forms of cyanidin-3-sophoroside-5-glucoside were predominant in cauliflower, while the sinapyl one was mostly present in red cabbage. All thermal treatments, except microwave heating, drastically reduced total cauliflower anthocyanin content.

From disrupted leaf tissues of cauliflower, the predominant vapour component was *cis*-hex-3-enyl acetate (Wallbank and Wheatley 1976). Apart from isothiocyanates, dimethyl disulphide was detected from cauliflower, particularly in vapour from disrupted curd tissue. From fresh Romanesco cauliflower Navona variety leaves extract, a total of 61 compounds were identified, representing 96.8 % of the oil (Valette et al. 2006). The major constituent was found to be hex-3(*Z*)-enol (61.1 %). From fresh disrupted inflorescence tissues of Romanesco, 35 compounds were detected, representing 97.7 % of the extract. Dimethyl disulphide, dimethyl trisulphide and hex-3(*Z*)-enol were identified as major constituents of the hydrodistillation products, representing, respectively, 30.2, 24.2 and 21.7 % of the volatiles. From ripening and frozen inflorescence tissues, dimethyl disulphide and trisulphide were again detected as predominant components. In the latter, hex-3(*Z*)-enol had almost disappeared (0.8 %) whereas dimethyl trisulphide represented 49.7 % of the oil. The steam distillation compounds present in the leaves and inflorescence tissues of cauliflower included limonene, α -pinene; β -pinene; α -terpineol; terpinene-4-ol; γ -terpinene; 4-methylene-1-(1-methylethyl)-bicyclo[3.1.0]hexane; nonanal; hexanal; camphor; decanal; eugenol; benzeneacetaldehyde; heptanal; 1-hexanol; (*E*)-2-hexenal; (*Z*)-3-hexen-1-ol;

(*E,E*)-2,4-decadienal; *trans*- β -ionone; furfural; pyridine; 2-buten-1-one, 1-(2,6,6-trimethyl-1,3-cyclohexadien-1-yl)-, (*E*)-; methional; pinocarvone; dimethyl disulphide; dimethyl trisulphide; 2-pentyl-furan; acetic acid, hexyl ester; hexadecanoic acid, methyl ester; benzyl benzoate; (*E,Z*)-2,6-nonadienal; (*Z*)-3-hexen-1-ol, acetate; indole; tetradecanal; 2-methoxy-4-vinylphenol; (*E*)-2-Hexen-1-ol; (*E,E*)-2,4-Heptadienal; 2,6-dimethylpyrazine; 1-(2-furanyl)-ethanone; pentadecanal; 2,6,6-trimethyl-1-cyclohexene-1-carboxaldehyde; tridecanal; 1-docecene; (*Z*)-3-hexen-1-ol, benzoate; 2-pentadecanone; butanoic acid, 3-hexenyl ester, (*Z*)-; 1-tridecene; dimethyl sulphoxide; dimethyl tetrasulphide; 2-acetylthiazole; 3-ethyl-phenol; (*Z*)-2-penten-1-ol; 2,6,6-trimethyl-1,3-cyclohexadiene-1-carboxaldehyde; 4-methyl-1-(1-methylethyl)-bicyclo[3.1.0]hex-3-en-2-one; 4-vinylphenol; 2-hexadecanone; (*E,E*)-3,5-octadien-2-one; 2,2,6-trimethyl-cyclohexanone; 1,2-dihydro-1,1,6-trimethyl naphthalene; 4-(2,2,6-trimethyl-7-oxabicyclo[4.1.0]hept-1-yl)-3-buten-2-one; methyl (methylthio)methyl disulphide; 1-(methylthio)pentane; β -damascone; *trans*-2-(2-pentenyl)furan; benzenepropanenitrile; 2,6,6-trimethyl-1-cyclohexene-1-acetaldehyde; benzene, (2-isothiocyanatoethyl)-; 4-methylthio-butyl isothiocyanate; 5-(methylthio)pentanenitrile; propane, 1-isothiocyanato-3-(methylthio)-; isobutyl isothiocyanate; 1-(methylthio)-3-pentanone; 4-methylthio butanenitrile; 2,6-dimethyl-3-methoxymethyl-p-benzoquinone; and 1,3,5-trimethyl-2-(1,3-butadienyl)benzene.

Environmental stress affecting harvest time was found to impact on the antioxidant properties and lipidic profile as quality indexes of cauliflower in a 3-year (2001–2003) study (Scalzo et al. 2007). Late harvested cauliflowers in 2002 were found to have a very different composition profile (increase of dry and fatty matter, polyphenols and antioxidant activity, decrease in ascorbic acid content) and a difference in fatty acid composition related to a relative increase in unsaturated fatty acids with respect to saturated ones.

Major volatile components identified in cauliflower included nonanal, octanol, 3-methylthiopropyl cyanide, 3-methylthiobutyl

cyanide, 2-phenylethyl cyanide and 2-phenylethyl isothiocyanate (Buttery et al. 1976). Volatiles emitted during blanching of cauliflowers included thiols, sulphides, polysulphides, aldehydes, isothiocyanates, nitriles, furans, esters, terpenes and carbonyl compounds (Van Langenhove et al. 1991). Aldehydes were the most abundant cauliflower volatiles. Blanching of purple, two white and two green varieties of cauliflower, prior to freezing, reduced total aliphatic and indole glucosinolates (GLS) by 31 and 37 %, respectively (Volden et al. 2009). L-ascorbic acid (L-AA), total phenols (TP), anthocyanins, FRAP (ferric reducing ability) and ORAC (oxygen radical absorbance capacity) were on average reduced by 19, 15, 38, 16 and 28 %, respectively. Long-term freezer storage did not markedly affect total aliphatic and indole GLS in cauliflower. Freezer storage did result in an average L-AA decrease of 24 % for all but the purple cultivar; smaller reductions in the TP levels were also found. Reductions in FRAP and ORAC values occurred towards the end of the storage period; the mean reductions were 15 and 37 %, respectively. Long-term freezer storage did not affect the anthocyanin content and only minor effects were found for the colour parameters.

Seed Phytochemicals

Forty-three compounds, representing more than 99.7 % of Romanesco cauliflower seed oil for the Natalino variety, 41 (99.6 %) for the Campidoglio variety and 32 (99.5 %) for the Navona variety, were identified (Valette et al. 2006). The major compounds were cyanides such as 4-(methylthio) butyl cyanide (61.3, 66.3 and 79.6 %, respectively), 3-(methylthio)propyl cyanide (21.7, 21.6 and 10.7 %) and isothiocyanates such as 4-(methylthio)butyl isothiocyanate (5.3, 4.0 and 6.7 %) for the three oils. The majority of identified volatile compounds were obtained by hydrolysis of glucosinolates. The compounds identified included nonanal; hexanal; benzeneacetaldehyde; phenylethyl alcohol; 6 methyl-5-hepten-2-one; (*E,E*)-2,4-decadienal; furfural; (*E*)-2-nonenal; methional; 2-pentyl-furan; indole; 1-hexadecanol; 2-methoxy-4-vinylphenol; 2-furanmethanol;

dihydro-5-pentyl-2(3H)-furanone; benzophenone; 1-octadecanol; 4-methoxy-6-(2-propenyl)-1,3-benzodioxole; benzyl nitrile; hexanenitrile; 6-methyl-5-hepten-2-ol; (*E,E*)-3,5-octadien-2-one; allyl isothiocyanate; benzene, (isothiocyanato-methyl)-; heptanenitrile; 4-isothiocyanato-1-butene; benzenepropanenitrile; isoamyl cyanide; benzene, (2-isothiocyanatoethyl)-; 5-methyl-hexanenitrile; 1-isothiocyanato-3-(methylthio)-propane; isobutyl isothiocyanate; 4-methylpentyl isothiocyanate; 5-methylthiopentyl isothiocyanate; pent-4-enenitrile; 1-isothiocyanato-3-methyl-butane and 4-(methylthio)-butanenitrile.

As seen from the above, cauliflower is low in fat and high in folate, dietary fibre and vitamin C and a good source of vitamin A, calcium, iron, manganese, riboflavin, niacin, thiamin, pantothenic acid and vitamin B6. It has beneficial antioxidant phenolics and flavonoids and glucosinolates and isothiocyanates with anticancer and other positive biological properties.

Antioxidant Activity

Cauliflower by-product extracts showed significant free radical scavenging activity (DPPH and ABTS radicals), ferric reducing ability (FRAP assay) and capacity to inhibit lipid peroxidation (ferric thiocyanate assay) (Llorach et al. 2003a). Furthermore, the antioxidant activity was linearly correlated with the phenolics content. The water and ethanol extraction of cauliflower yielded a phenolic content of 33.8 mg/g freeze-dried extract and 62.1 mg/g freeze-dried extract, respectively. This percentage increased considerably when the extracts were purified yielding a phenolic content of 186 mg/g freeze-dried extract (water extract) and 311.1 mg/g freeze-dried extract (ethanol extract). The results indicated that the cauliflower by-products are a cheap source of antioxidant phenolics.

Cauliflower glucosinolates and their derivatives were found to have significant antioxidant capacity in the oxygen radical absorbance capacity (ORAC) and superoxide radical scavenging activity (SRSA) assays especially glucobrassicin, followed by glucoiberin and gluconapin

(Cabello-Hurtado et al. 2012). In contrast the antioxidant activities of the glucosinolates in the 2,2-diphenyl-1-picrylhydrazyl (DPPH) and 2,2'-azino-bis-(3-ethyl-benzothiazoline-6-sulphonic acid) (ABTS) assays were weak. There was no synergy or antagonism between glucosinolates. Breakdown products of glucosinolates were far more active than the native glucosinolates. The highest increases in antioxidant activity were obtained for enzymatic hydrolysis-derived products (EHDP) from progoitrin, sinigrin and glucoraphanin, progoitrin EHDP being the second most active derivative behind glucobrassicin EHDP. Overall, the contribution of glucosinolates to antioxidant activity of cauliflower appeared low.

Anticancer Activity

In-Vitro Studies

Three indole compounds indole-3-acetonitrile, indole-3-carbinol and 3,3'-diindolylmethane were identified from three cruciferous vegetables, Brussels sprouts, cabbage and cauliflower (Loub et al. 1975; Wattenberg 1975). These indoles were found to be naturally occurring inducers of aryl hydrocarbon hydroxylase (Loub et al. 1975) and microsomal mixed function oxidase system and to exert a protective effect against chemical carcinogens (Wattenberg 1975). Besides these indoles, other naturally occurring inducers include flavones, safrole, isosafrole, β -ionone and oxidized sterols (Wattenberg et al. 1976). Thus, the composition of the diet could play a role in inhibiting the neoplastic response to carcinogenic agents.

Indole-3-carbinol (I3C), a secondary plant metabolite produced in vegetables of the *Brassica* genus, including cabbage, cauliflower and Brussels sprouts, could be both an anti-initiator and a promoter of carcinogenesis (Bjeldanes et al. 1991). Consumption of I3C by humans and rodents could lead to marked increases in activities of cytochrome P-450-dependent monooxygenases and in a variety of phase II drug-metabolizing enzymes. They reported previously that the enzyme-inducing activity of I3C was mediated through a mechanism requiring exposure of the

compound to the low-pH environment of the stomach. They found that indolo[3,2-b]carbazole (ICZ), a major acid condensation product generated from I3C in the order of 0.01 % in-vitro and, after oral intubation, in-vivo to be an aromatic hydrocarbon responsiveness-receptor agonist and to induce cytochrome P4501A1 activity in murine hepatoma Hepa 1c1c7 cells. Isothiocyanates and indoles (e.g. indole-3-carbinol) from *Brassica* vegetables (e.g. broccoli, cauliflower) induce phase I and phase II enzymes responsible for the oxidation, reduction and metabolism of endogenous and exogenous carcinogens (Fowke et al. 2006). Oral administration of indole-3-carbinol (I3C) had been shown to manipulate oestrogen metabolism in humans in a possibly beneficial manner (Brignall 2001). I3C increased the 2/16-hydroxyestrone ratio, a ratio found to be predictive of breast cancer risk in some prospective studies. Animal and in-vitro studies had identified a number of other possibly beneficial effects of I3C and its metabolites, including inhibition of oestrogen binding and modulation of oncogene expression. A chemopreventive effect of I3C had been demonstrated in a number of animal models. Some chemical carcinogenesis models had found a tumour-promoting effect of I3C, however. Ascorbigen, a derivative of indole-3-carbinol may partly mediate the known anticarcinogenic effect of diets rich in Brassicaceae (Wagner and Rimbach 2009). Further, ascorbigen could induce phase I and II enzymes centrally involved in the detoxification of xenobiotics.

Both indole-3-carbinol (I3C) and diindolylmethane (DIM) from *Brassica* vegetables were found to be partial aryl hydrocarbon (Ah) receptor antagonists in the T47D human breast cancer cell line (Chen et al. 1996). In aryl hydrocarbon (Ah)-responsive T47D human breast cancer cells, I3C and DIM did not induce significantly CYP1A1-dependent ethoxyresorufin O-deethylase (EROD) activity or CYP1A1 mRNA levels at concentrations as high as 125 or 31 μ M, respectively. In T47D cells co-treated with 5 nM [3H] TCDD (2,3,7,8-tetrachlorodibenzo-p-dioxin) alone or in combination with 250 μ M I3C or 31 μ M DIM, there was a 37 and 73 % decrease,

respectively, in formation of the nuclear Ah receptor. The more effective inhibition of induced EROD activity by I3C and DIM was due to in-vitro inhibition of enzyme activity. Firestone and Bjeldanes (2003) found that indole-3-carbinol and 3,3'-diindolylmethane antiproliferative signalling pathways controlled cell-cycle gene transcription in human MCF-7 breast cancer cells by regulating nuclear promoter-Sp1 transcription factor interactions.

Following ingestion of *Brassica* vegetables, indole-3-carbinol (I3C) is converted to a series of oligomeric products that presumably are responsible for the in-vivo effects of I3C; tumour-promoting effects of high doses of I3C may be due to activation of aryl hydrocarbon receptor (AhR)-mediated pathways (Riby et al. 2000). Hong et al. (2002) found that 3,3'-diindolylmethane (DIM), a major in-vivo derivative of the putative anticancer agent indole-3-carbinol, could induce apoptosis in breast cancer cells independent of oestrogen receptor status by a process mediated by the modulated expression of the Bax/Bcl-2 family of apoptotic regulatory factors. Degner et al. (2009) found that co-treatment of MCF-7 breast cancer cells with 3,3'-diindolylmethane (DIM) (10 μ mol/l) abrogated the xenobiotic 2,3,7,8 tetrachlorodibenzo (p)dioxin (TCDD)-induced recruitment of the aryl hydrocarbon receptor and acetylated histone H4 to the acetylated histone H4 promoter and the induction of COX-2 mRNA and protein levels. The data suggested that naturally occurring modulators of the aryl hydrocarbon receptor such as DIM may be effective agents for dietary strategies against epigenetic activation of COX-2 expression by aryl hydrocarbon receptor agonists. In another study, 3,3'-diindolylmethane (DIM), a putative anticarcinogenic agent formed in the acidic environment of the stomach following consumption of indole-3-carbinol (I3C), inhibited the proliferation of three human breast cancer cell lines, MCF-7, MDA-MB-231 and SKBr-3 and concomitantly inhibited the expression of transcription factor Sp1 and fatty acid synthase (FAS) but not in nontumorigenic human breast epithelial cell line MCF-10A (Saati and Archer 2011).

A major trimeric product of I3C, 5,6,11,12,17,18-hexahydrocyclonona[1,2-b:4,5-b':7,8-b'']triindole (CTr) was found to be a strong agonist of the oestrogen receptor signalling pathway (Riby et al. 2000; Xue et al. 2005). CTr stimulated the proliferation of oestrogen-responsive MCF-7 cells to a level similar to that produced by estradiol (E(2)) but did not affect the growth of the oestrogen-independent cell line, MDA-MD-231. CTr failed to activate AhR-mediated pathways, consistent with the low-binding affinity of CTr for the AhR reported previously. CTr increased proliferation of oestrogen-dependent breast tumour cells, bound with strong affinity for the oestrogen receptor- α (ER α) and activated expression of oestrogen (E(2))-dependent genes (Xue et al. 2005). Analysis of growth and cell-cycle arrest of indole-treated human breast cancer cells revealed a striking increase in efficacy of the N-alkoxy indole-3-carbinol (I3C) derivatives that was significantly enhanced by the presence of increasing carbon lengths of the N-alkoxy substituents (Jump et al. 2008). Compared to I3C, the half maximal growth arrest responses occurred at 23-fold lower indole concentration for N-methoxy I3C, 50-fold lower concentration for N-ethoxy I3C, 217-fold lower concentration for N-propoxy I3C and 470-fold lower concentration for N-butoxy I3C. At these lower concentrations, each of the N-alkoxy substituted compounds induced the characteristic I3C response in CDK6 gene expression, CDK6 promoter activity and CDK2-specific enzymatic activity for its retinoblastoma protein substrate and was strongly downregulated. 3-Methoxymethylindole and 3-ethoxymethylindole were approximately as bioactive as I3C, whereas both tryptophol and melatonin failed to induce the cell-cycle arrest, showing the importance of the C-3 hydroxy methyl substituent on the indole ring. The results indicated I3C-based N-alkoxy derivatives to be a novel class of potentially more potent experimental therapeutics for breast cancer.

Indole-3-carbinol was found to inhibit the expression of cyclin-dependent kinase-6 (CDK6) and induced a G1 cell-cycle arrest of human MCF7 breast cancer cells independent of oestrogen receptor signalling (Cover et al. 1998). The

antioestrogen tamoxifen also suppressed MCF7 cell DNA synthesis but had no effect on CDK6 expression. Combinations of indole-3-carbinol (I3C) and the antioestrogen tamoxifen inhibited the growth of the oestrogen-dependent human MCF-7 breast cancer cell line more effectively than either agent alone (Cover et al. 1999). This more stringent growth arrest was demonstrated by a decrease in adherent and anchorage-independent growth, reduced DNA synthesis and a shift into the G1 phase of the cell cycle. A combination of I3C and tamoxifen also caused a more pronounced decrease in cyclin-dependent kinase (CDK) 2-specific enzymatic activity than either compound alone but had no effect on CDK2 protein expression. Also, treatment with I3C and tamoxifen eroded expression of the phosphorylated retinoblastoma protein (Rb), an endogenous substrate for the G1 CDKs, whereas either agent alone only partially inhibited endogenous Rb phosphorylation.

Indole-3-carbinol (I3C) could induce a G(1) cell-cycle arrest of human MCF-7 breast cancer cells through inhibition of cyclin-dependent kinase 6 (CDK6) expression by disrupting Sp1 transcription factor interactions with DNA composite element in CDK6 gene promoter (Cram et al. 2001). Sarkar et al. (2003) found that translocation of Bax to the mitochondria followed by mitochondrial depolarization and cytochrome C release was necessary and important that may be responsible for selective induction of apoptosis cell death by indole-3-carbinol (I3C) treatment of breast cancer cells. Matsuzaki et al. (2004) demonstrated that I3C activated the cyclin-dependent kinase (CDK) inhibitor p15INK4b gene through its promoter, accompanied by cell growth inhibition in human adult keratinocyte HaCaT cells. Studies showed that one mechanism by which indole-3-carbinol (I3C)-mediated anticancer effects was by stimulating expression of the interferon IFN- γ R1 and augmenting the IFN- γ response in MCF-7 human breast cancer cells (Chatterji et al. 2004).

Treatment of highly invasive MDA-MB-231 breast cancer cells with indole-3-carbinol (I3C) shifted the stable accumulation of cyclin E protein from the hyperactive lower-molecular-mass 35-kDa form associated with cancer cell

proliferation and poor clinical outcomes to the 50-kDa cyclin E form typically expressed in normal mammary tissue (Nguyen et al. 2008). It was demonstrated that I3C, but not its natural dimer, 3,3'-diindolylmethane, disrupted proteolytic processing of the 50-kDa cyclin E into the lower-molecular-mass forms by direct inhibition of human neutrophil elastase enzymatic activity. The results suggested that the direct I3C inhibition of elastase enzymatic activity implicated the potential use of this indole, or related compounds, in targeted therapies of human breast cancers where high elastase levels were correlated with poor prognosis.

Both indole-3-carbinol (I3C) and genistein induced the expression of both breast cancer susceptibility genes (BRCA1 and BRCA2) in breast (MCF-7 and T47D) and prostate (DU-145 and LNCaP) cancer cell types, in a time- and dose-dependent fashion (Fan et al. 2006). Induction of the BRCA genes occurred at low doses of I3C (20 μ M) and genistein (0.5–1.0 μ M), suggesting potential relevance to cancer prevention. A combination of I3C and genistein afforded greater than expected induction of BRCA expression. Studies using small interfering RNAs (siRNAs) and BRCA expression vectors suggested that the phytochemical induction of BRCA2 was due, partly to BRCA1. Functional studies suggested that I3C-mediated cytotoxicity was, in part, dependent upon BRCA1 and BRCA2. It was also shown that the phytochemical induction of BRCA1 expression was due, in part, to endoplasmic reticulum stress response signalling. Oestrogen receptor (ER)alpha is a critical target of therapeutic strategies to control the proliferation of hormone-dependent breast cancers, and studies had shown that indole-3-carbinol (I3C) eroded ERalpha expression (Marconett et al. 2010). It was found that I3C-dependent activation of the aryl hydrocarbon receptor (AhR) initiated Rbx-1 E3 ligase-mediated ubiquitination and proteasomal degradation of ERalpha protein. I3C inhibited endogenous binding of ERalpha with the 3'-enhancer region of GATA3 and disrupted endogenous GATA3 interactions with the ERalpha promoter, leading to a loss of GATA3 and ERalpha expression. The preclinical results

implicated I3C to be a novel anticancer agent in human cancers that coexpress ERalpha, GATA3 and AhR, a combination found in a large percentage of breast cancers but not in other critical ERalpha target tissues essential to patient health. In-vitro and in-vivo studies in a mouse xenograft model showed that indole-3-carbinol (I3C)-induced activation of the ATM-Chk2 pathway and degradation of cell division cycle 25A (Cdc25A) phosphatase represented a novel molecular mechanism of I3C in arresting the G(1) cell cycle and inhibiting the growth of breast cancer cells (Wu et al. 2010). The finding that I3C induced Cdc25A degradation suggested the potential use of this agent for preventing and treating cancers and other human diseases with Cdc25A overexpression.

Isothiocyanates (ITCs) and indoles derived from cruciferous vegetables had been reported to possess growth-inhibiting and apoptosis-inducing activities in cancer cell lines in-vitro (Pappa et al. 2007). ITCs like sulforaphane (SFN) were cytotoxic, whereas indoles including indole-3-carbinol or its condensation product 3,3'-diindolylmethane (DIM) acted by cytostatic mechanisms in human colon cancer cell lines. In cultured 40–16 colon carcinoma cells, at a total drug concentration of 2.5 microM, all combinations of SFN and DIM were antagonistic. SFN (10 μ M) in combination with DIM (10 μ M) resulted in strong G(2)/M cell-cycle arrest, which was not observed with either compound alone. The results indicated that cytotoxic concentrations of SFN:DIM combinations affected cell proliferation colon cancer cell synergistically.

Indole-3-carbinol (I3C) inhibited the growth of PC-3 prostate cancer cells in-vitro by inducing G1 cell-cycle arrest leading to apoptosis and regulating the expression of apoptosis-related genes (Chinni et al. 2001). They found that I3C-induced apoptosis was partly mediated by the inhibition of Akt kinase activation, resulting in the alterations in the downstream regulatory molecules of Akt/PI3K cell survival pathway, Bcl-x(L) and BAD proteins in PC-3 prostate cancer cells (Chinni and Sarkar 2002). Additionally, I3C abolished epidermal growth factor (EGF)-induced activation of Akt in PC-3 cells.

Zhang et al. (2003) reported that I3C suppressed the growth of LNCaP prostate carcinoma cells in a dose-dependent manner by inducing a G1 block in cell-cycle progression. I3C selectively inhibited the expression of CDK6 protein and transcripts and strongly stimulated the production of the p16 CDK inhibitor. In LNCaP prostate carcinoma cells, I3C treatment inhibited production of PSA, whereas combinations of I3C and the androgen antagonist flutamide more effectively inhibited DNA synthesis and PSA levels compared with either agent alone. In another study, I3C was shown to induce a G(1) cell-cycle arrest in the cells of human lymph node carcinoma of prostate (LNCaP) through regulation of specific G(1)-acting cell-cycle components and to inhibit androgen receptor expression and downregulation of androgen responsiveness in human prostate cancer cells as a part of its antiproliferative mechanism (Hsu et al. 2005). Further, they found that indole-3-carbinol induced G1 arrest of LNCaP human prostate cancer cells necessitating the induced production of the activated phosphorylated forms of p53 tumour suppressor protein, which stimulated transcription of the cyclin-dependent kinase (CDK) 2 inhibitor p21 (Hsu et al. 2006). Wang et al. (2012) found that indole-3-carbinol (I3C) and 3,3'-diindolylmethane (DIM) exerted concentration-dependent pleiotropic effects on prostate cancer cells via signalling pathways that included proliferation, cell cycle and nuclear receptors-mediated pathways. However, the efficacies and mechanisms of these compounds varied according to differences in effective concentrations, a differential effect on androgen receptor binding and a differential effect on xenobiotic metabolic pathway through aryl hydrocarbon receptor-dependent and receptor-independent mechanism. Both compounds inhibited androgen and oestrogen-mediated pathways and induced xenobiotic metabolism pathway at 1–5 μ M. In contrast-induced cyclin inhibitors, indicators of stress/DNA damage only at ≥ 25 μ M.

In-vitro studies by Takada et al. (2005) demonstrated that indole-3-carbinol (I3C) suppressed nuclear factor-kappaB (NF-kappaB) and IkappaBalph kinase activation, inhibited

expression of NF-kappaB-regulated antiapoptotic and metastatic gene products and enhanced apoptosis in myeloid and leukaemia cells. I3C suppressed IkappaBalph kinase, IkappaBalph phosphorylation, IkappaBalph ubiquitination, IkappaBalph degradation, p65 phosphorylation, p65 nuclear translocation, p65 acetylation and NF-kappaB-dependent reporter gene expression. The NF-kappaB-regulated gene products cyclin D1, cyclooxygenase-2 (COX-2), matrix metalloproteinase-9 (MMP-9), survivin, inhibitor of apoptosis protein 1 (IAP1), IAP2, X chromosome-linked IAP (XIAP), Bcl-2, Bfl-1/A1, TNF receptor-associated factor-1 (TRAF1) and Fas-associated death domain protein-like interleukin-1-beta-converting enzyme inhibitory protein (FLIP) were all downregulated by indole-3-carbinol. Another in-vitro study showed that indole-3-carbinol (I3C) inhibited cell viability of human T-cell leukaemia virus type-infected T-cell lines and adult T-cell leukaemia/lymphoma cells in a dose-dependent manner but not uninfected T-cell lines and normal peripheral blood mononuclear cells (Machijima et al. 2009). I3C prevented the G1/S transition by reducing the expression of cyclin D1, cyclin D2, Cdk4 and Cdk6 and induced apoptosis by reducing the expression of XIAP, survivin and Bcl-2 and by upregulating the expression of Bak. The induced apoptosis was associated with activation of caspase-3, -8 and -9 and poly(ADP-ribose) polymerase cleavage. I3C also suppressed IkappaBalph phosphorylation and JunD expression, resulting in inactivation of NF-kappaB and AP-1.

In-vitro, indole-3-carbinol (I3C) had been shown to suppress the proliferation of various tumour cells including breast cancer, prostate cancer, endometrial cancer, colon cancer and leukaemic cells; induce G1/S arrest of the cell cycle; and induce apoptosis (Aggarwal and Ichikawa 2005). The cell-cycle arrest involved downregulation of cyclin D1, cyclin E, cyclin-dependent kinase (CDK) 2, CDK4 and CDK6 and upregulation of p15, p21 and p27. Apoptosis by I3C involved downregulation of antiapoptotic gene products, including Bcl-2, Bcl-xL, survivin, inhibitor of apoptosis protein (IAP), X

chromosome-linked IAP (XIAP) and Fas-associated death domain protein-like interleukin-1-beta-converting enzyme inhibitory protein (FLIP); upregulation of proapoptotic protein Bax; release of mitochondrial cytochrome C; and activation of caspase-9 and caspase-3. Under acidic conditions, I3C had been reported to be converted to a series of oligomeric products (e.g. 3,3'-diindolylmethane a major component) thought to be responsible for its biological effects in-vivo.

In-Vivo Studies

In-vivo, I3C was found to be a potent chemopreventive agent for hormonal-dependent cancers such as breast and cervical cancer (Aggarwal and Ichikawa 2005). These effects were found to be mediated through its ability to induce apoptosis, inhibit DNA-carcinogen adduct formation and suppress free radical production, stimulate 2-hydroxylation of estradiol and inhibit invasion and angiogenesis. Numerous studies had indicated that I3C also had a strong hepatoprotective activity against various carcinogens. Initial clinical trials in women had shown I3C to be a promising agent against breast and cervical cancers.

Indole-3-carbinol (I3C) was found to be an inhibitor in several experimental animal models of carcinogenesis by polynuclear aromatic hydrocarbons or aflatoxin B1 (AFB1) when administered prior to or during carcinogen exposure (Bailey et al. 1987). Pre-initiation exposure to I3C reduced AFB1-initiated hepatocellular carcinomas in trout, but post-initiation I3C exposure strongly enhanced the tumour incidence above the positive AFB1 control.

Studies showed that feeding of rats with S-methyl methanethiosulfonate (MMTS) isolated from cauliflower prevented azoxymethane-induced colon carcinogenesis (Kawamori et al. 1995). In experiment 1, feeding of 100 ppm MMTS for 5 weeks significantly decreased the number of aberrant crypt foci/colon. Colonic mucosal ornithine decarboxylase activity and the number of silver-stained nucleolar organizer regions per nucleus in colonic epithelium were significantly decreased by MMTS treatment compared with those of azoxymethane alone.

In experiment 2, incidence of intestinal neoplasms of rats fed MMTS-containing diets after azoxymethane exposure was reduced in a dose-dependent manner. Feeding of MMTS during the post-initiation phase decreased the number of aberrant crypt foci/colon, colonic ornithine decarboxylase activity, 5-bromodeoxyuridine-labelling index in colonic epithelium and polyamine level in blood compared with those of azoxymethane alone. In another study, compared with control rats given the carcinogen, 2-amino-3-methylimidazo[4,5-f]quinoline (IQ) alone, 0.1 % indole-3-carbinol (I3C) treatment suppressed the multiplicity of IQ-induced colon tumours in male F344 rats and chlorophyllin, a water-soluble derivative of chlorophyll in leafy vegetables, inhibited in a dose-related manner the incidence of IQ-induced liver tumours (Xu et al. 2001). However, 0.001 % chlorophyllin increased significantly the multiplicity of 1,2-dimethylhydrazine-induced colon tumours while having no effect on the colon tumours induced by IQ. The results indicated that both the choice of carcinogen and the dose of the tumour modulator could be important determinants of the events that occur during post-initiation exposure to chlorophyllin or I3C. Based on the present findings and data in the literature, chlorophyllin and I3C could act as tumour promoters or anticarcinogens, depending upon the test species, initiating agent and exposure protocol.

The results of in-vitro studies by Rahman et al. (2006) suggested that indole-3-carbinol (I3C) could be a promising agent for the prevention and/or treatment of breast cancer bone metastasis. In the severe combined immunodeficient (SCID)-human mouse model of experimental bone metastasis with MDA-MB-231 breast cancer cell line, I3C significantly inhibited MDA-MB-231 bone tumour growth. The results were correlated with the downregulation of NF-kappaB. Further, I3C significantly inhibited the expression of multiple genes involved in the control of metastasis and invasion in-vitro and in-vivo, especially the expression of chemokine receptor CXCR4 and matrix metalloproteinases MMP-9 along with pro-MMP-9, with concomitant

decrease in Bcl-2 and increase in the proapoptotic protein Bax. They concluded that the CXCR4/NF-kappaB pathway was critical during I3C-induced inhibition of experimental breast cancer bone metastasis. 3'-Diindolylmethane (DIM), a major in-vivo acid-catalyzed condensation product of I3C, also showed some benefit in breast cancer (Rahman and Sarkar 2005). DIM was found to induce apoptotic processes in MCF10A-derived malignant (MCF10CA1a) cell lines but not in nontumorigenic parental MCF10A cells. DIM specifically inhibited Akt kinase activity and abrogated the epidermal growth factor-induced activation of Akt in breast cancer cells, similar to those observed for I3C. Also DIM reduced phosphorylation of IkappaBalpha, an inhibitor of NF-kappaB. In-vitro and in-vivo studies in a mouse xenograft model showed that indole-3-carbinol (I3C)-induced activation of the ATM-Chk2 pathway degradation of cell division cycle 25A (Cdc25A) phosphatase arrested the G(1) cell cycle and inhibited the growth of breast cancer cells (Wu et al. 2010). The authors suggested that I3C had potential for preventing and treating cancers and other human diseases with Cdc25A overexpression.

Intragastric administration of indole-3-carbinol (I3C) and phenethyl isothiocyanate (PEITC), from *Brassica* plants (cauliflower, broccoli, cabbage, etc.) to male Fischer rats for 5 days, was found to significantly increase bile excretion and γ -glutamyl transpeptidase (γ -GTP) activity compared to control rats, but no difference was observed in the pancreatic juice (Ishibashi et al. 2012). Increases of bile excretion and γ -GTP activity in bile might be a factor involved in the anticancer effect of I3C and PEITC.

Indole-3-carbinol suppressed growth of murine WEHI-3 leukaemia cells in-vitro and caused morphological changes (DNA fragmentation and chromatin condensation) in a concentration- and time-dependent manner (Lu et al. 2012). It elicited G0/G1 phase arrest and the levels of cyclin A, cyclin D and CDK2 and increased the levels of p21, cytochrome C, FADD, GADD153, GRP78 and caspase-12 as well as induced activities of caspase-3, -8 and -9. In vivo, I3C increased the level of T cells and decreased the level of macro-

phages in WEHI-3 leukaemia mice. I3C also reduced the weights of liver and spleen, and it promoted phagocytosis by macrophages as compared to the non-treated leukaemia mice group.

Studies showed that supplementation of the diet of carcinogen (a mixture of 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone (NNK) and benzo[a]pyrene (BaP))-treated mice with indole-3-carbinol (I3C) reduced the elevated levels of pulmonary surfactant-associated protein C (SP-C), L-plastin, annexin A1 and haptoglobin to that of untreated controls (Kassie et al. 2007). The results suggested that the lung tumour chemopreventive activity of I3C might be related to modulation of carcinogen-induced alterations in protein levels.

Preliminary human trials had demonstrated that I3C was well tolerated and had a sustained oestrogen-modifying effect and to be a good candidate for clinical trial in women at increased risk of developing breast cancer (Brignall 2001). *Brassica* intake has been associated with reduced risk of colon, lung, bladder, breast, prostate and other cancers (Fowke et al. 2006). In a randomized crossover trial ($n=20$) comparing the effects of a *Brassica* vegetable supplementation intervention against a micronutrient and fibre (M+F) supplementation, *Brassica* intervention was found to significantly decrease urinary F2-isoprostane levels (F2-iP), a stable biomarker of systemic oxidative stress by 21 % compared to baseline and (M+F) intervention (Fowke et al. 2006). Their results suggested that *Brassica* consumption reduces systemic oxidative stress independent of the vitamin and mineral content of these vegetables.

Hecht et al. (2004) investigated the effects of cruciferous vegetable (including cauliflower, broccoli) consumption on the metabolism of the tobacco-specific lung carcinogen 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone (NNK) in 84 smokers. They found that glucobrassicins, which release indole-3-carbinols on chewing, were the major glucosinolates in seven of the nine cruciferous vegetables, accounting for 70.0–93.2 % of all glucosinolates in these vegetables. There was a significant correlation ($P=0.01$) between increased consumption of glucobrassicins and decreased levels of metabolites of NNK:

4-(methylnitrosamino)-1-(3-pyridyl)-1-butanol (NNAL) and its glucuronides (NNAL-Glucs) in urine after adjustment for number of cigarettes smoked per day. Their results were consistent with those of previous studies, which demonstrated that indole-3-carbinol decreased levels of urinary NNAL probably by inducing hepatic metabolism of NNK.

In a prospective study of fruit and vegetable intake and risk of prostate cancer, involving 1,338 patients with prostate cancer among 29,361 men (average follow-up=4.2 years) in the screening arm of the Prostate, Lung, Colorectal and Ovarian Cancer Screening Trial, Kirsh et al. (2007) found that a high intake of cruciferous vegetables, including broccoli and cauliflower, may be associated with reduced risk of aggressive prostate cancer, particularly extra-prostatic disease.

Review Studies

The results of 7 cohort studies and 87 case-control studies on the association between *Brassica* consumption and cancer risk showed inverse associations between the consumption of cabbage, cauliflower and broccoli and risk of lung cancer; between the consumption of Brassicas and risk of stomach cancer; between broccoli consumption and risk of all cancers taken together; and between *Brassica* consumption and the occurrence of second primary cancers (Verhoeven et al. 1996). Of the case-control studies, 67 % showed an inverse association between consumption of total *Brassica* vegetables and risk of cancer at various sites. For cabbage, broccoli, cauliflower and Brussels sprouts, these percentages were 70, 56, 67 and 29 %, respectively. Although the measured effects might have been distorted by various types of bias, it was concluded that a high consumption of *Brassica* vegetables was associated with a decreased risk of cancer.

Hepatoprotective Activity

Indole-3-carbinol did not show an enhancement effect on quinone reductase activity

(associated with anticarcinogenic processes), but its acidic derivative, indolo[3.2-b]carbazole (ICZ), increased the expression of quinone reductase mRNA, which then caused the augmentation of quinone reductase activity in murine Hepa-1 and human (HepG2) hepatoma cells (Chen and Yang 2002). Indole-3-carbinol (I3C) was found to have protective effect in-vitro on acute ethanol-induced hepatotoxicity and acetaldehyde-stimulated hepatic stellate cells (HSC) activation using precision-cut liver slices (Guo et al. 2010). It was found that the hepatoprotective effect may be associated with the regulation of ethanol metabolic enzymes, attenuation of oxidative injury and acceleration of collagen degradation. Ping et al. (2011b) found that I3C could significantly inhibit hepatic stellate cell proliferation during the course of liver fibrosis, in a concentration-dependent manner with or without platelet-derived growth factor-BB (PDGF-BB) stimulation. I3C could also block hepatic stellate cell in the G(0)/G(1) phase from entering the S phase. They concluded that I3C could inhibit the proliferation of hepatic stellate cell by blocking the NADPH oxidase/reactive oxygen species/p38 MAPK signal pathway. The results suggested that dietary I3C might play a novel role in prevention and treatment of chronic liver disease. Studies showed that indole-3-carbinol (I3C) treatment significantly reduced the number of activated hepatic stellate cells (HSC) in the livers of rats with liver fibrosis (Ping et al. 2011a). I3C significantly increased the HSC-T6 apoptosis rate and the expression ratio of Bax to Bcl-2 by the inhibitor of κ B kinase α /inhibitor of κ B- α /nuclear factor- κ B pathway. Administration of cauliflower extract for 5, 10 and 15 days was found to reduce the level of alanine transaminase and improved the microscopic appearance of hepatic cells in Wistar rats given a single dose of theophylline (Sunarsih et al. 2012). Ethanol extract of cauliflower exhibited cytotoxic effect against hepatic carcinoma induced by diethylnitrosamine (DEN) (1 μ l/100 g b.wt.) in rats (Hamed et al. 2012). The extract elicited 33.30 % inhibition of carcinogenic hepatic cells.

Hypolipidaemic Activity

Indole-3-carbinol (I3C) was found to dose-dependently inhibit apolipoprotein B-100 (apoB) production in HepG2 cells and to have beneficial effects on lipid synthesis that could contribute to their potential cardioprotective effects (Maiyoh et al. 2007). Significant decreases in cellular lipid synthesis, including triglycerides and cholesterol esters, were observed in HepG2 cells treated with I3C, indicating limited lipid availability to be a major factor in the regulation of apoB secretion. The decrease in triglycerides synthesis was associated with significantly decreased diacylglycerol acyltransferase-1 and -2 activity and reduced fatty acid synthase (FASN) gene expression. The decreased cholesterol esters synthesis was associated with significantly decreased acyl CoA:cholesterol acyltransferase gene expression and activity.

In-vitro studies showed that indole-3-carbinol (I3C) ameliorated adipogenesis by activating SIRT1 (silent mating type information regulation 2 homolog 1), a NAD(+)-dependent deacetylase sirtuin in 3T3-L1 (adipose-like) cells (Choi et al. 2012b). I3C treatment reduced mRNA levels of adipogenic genes that encode for C/EBP α , PPAR γ 2, FAS and aP2 in 3T3-L1 cells but not in SIRT1 knockdown cells. Indole-3-carbinol supplementation significantly ameliorated 40 % energy, high fat diet (HFD)-induced increases in mice body weight gain, visceral fat pad weights and plasma lipid levels (Choi et al. 2012a). It was found that indole-3-carbinol prevented obesity and metabolic disorders in mice through multiple mechanisms including decreased adipogenesis and inflammation, along with activated thermogenesis.

Antimutagenic Activity

S-methyl methanethiosulfonate isolated from cauliflower was found to have antimutagenic activity to *Escherichia coli* B/r WP2 (Nakamura et al. 1993). High pressure or freezing treatment of cauliflower juice exerted positive AFTB1 (aflatoxinB1) mutagen inhibition. In the Ames mutagenic test using *Salmonella typhimurium* TA 100, high pressure or freezing treatment of cauli-

flower juice exerted strongly positive test MNU (2-nitroso-2-methylurea) mutagen inhibition (Totušek et al. 2011). In the Ames mutagenic test using *Salmonella typhimurium* TA 98, high pressure or freezing treatment of cauliflower juice exerted strongly positive test on IQ (2-amino-3-methyl-3H-imi-dazo-[4,5-f]quinoline) mutagen inhibition.

Antiinflammatory Activity

In-vitro studies showed that 2-phenylethyl isothiocyanate (PEITC) and indole-3-carbinol (I3C), from *Brassica* vegetables, inhibited lipopolysaccharide (LPS)- and interferon-gamma (IFN-gamma)-induced NO production in RAW 264.7 cells, and this inhibition was associated with lowering the expression of iNOS protein and mRNA (Chen et al. 2003). In contrast, indolo[3,2-b]carbazole (ICZ), a derivative of I3C, had no significant effect on the stimulated NO production. Inhibition of iNOS expression or activity is an important therapeutic goal.

In vitro studies showed that indole-3-carbinol (I3C), a natural hydrolysis product of glucobrassicin, inhibited LPS-induced inflammatory response by blocking TRIF-dependent signalling pathway Raw264.7 cells and THP-1 cells (Jiang et al. 2013). Further, I3C suppressed the infiltration of immune cells into the lung and proinflammatory cytokine production such as IL-6, TNF- α in broncho-alveolar lavage fluid (BALF) in the LPS-induced acute lung injury mouse model and also suppressed IL-1 β secretion in nigericin treated in-vivo model. The results suggested that indole-3-carbinol may provide a valuable therapeutic strategy in treating various inflammatory diseases.

Antiplatelet and Antithrombotic Activity

The results of in-vitro and in-vivo studies suggested that indole-3-carbinol, present in cauliflower, could be a potent antithrombotic agent with antiplatelet activity through the inhibition of GP IIb/IIIa receptor and thromboxane B2 formation (Park

et al. 2008). Indole-3-carbinol significantly and dose-dependently inhibited collagen-induced platelet aggregation in human platelet-rich plasma and fibrinogen binding to the platelet surface glycoprotein IIb/IIIa (GP IIb/IIIa) receptor. Further, the levels of thromboxane B2 and prostaglandin E2 (PGE2) in collagen-stimulated human platelet-rich plasma were significantly inhibited. In-vivo, it dose-dependently suppressed the death of mice with pulmonary thrombosis induced by intravenous injection of collagen and epinephrine.

Antihyperglycaemic Activity

Cauliflower extract was found to decrease the hyperglycaemic but not the area under the glucose tolerance curve (Roman-Ramos et al. 1995).

Microbial Activity

Fresh cauliflower juice was found to be effective both in inhibiting the growth of blastoconidia and reducing the appearance of *C. albicans* germ tubes (Sisti et al. 2003). The juice also inhibited the growth of some pathogenic, filamentous fungi.

Blood Labelling Studies

The cauliflower leaf extract did not alter the labelling of blood elements with technetium-99 m; however, it abolished the lethal effect of SnCl₂ on the *Escherichia coli* culture (Lima et al. 2002). It was suggested that the oxidant action of the substances of the extract would not be strong enough to oxidize the stannous ions altering the 99mTc-labelling. However, the referred substances could oxidize these ions sufficiently to protect the *E. coli* culture against the lethal effect of the stannous ion.

Antilcerogenic Activity

Oral administration of indole-3-carbinol alone or in combination with omeprazole to aspirin-

ulcerated rats for 7 days produced a profound protection to the gastric mucosa from injury induced by aspirin (El-Shinnawy et al. 2012).

Skin Protective Activity

Brassica degradation products of sulforaphane (SFN) and glucobrassicin, the precursor of indole-3-carbinole (I3C) and ascorbigen (ABG), was tested on their efficacy in inducing cytoprotective genes in the skin, namely, Nrf2-dependent gene expression in human keratinocytes in culture (Wagner et al. 2010). They found SFN but not ABG, and its precursors I3C and ascorbic acid induced Nrf2-dependent gene expression at a relatively low concentration (5 µmol/l). This induction was accompanied by an increase in mRNA and protein levels of NADPH quinone oxidoreductase 1, heme oxygenase 1 and gamma-glutamylcysteine synthetase. Also SFN elevated cellular glutathione levels and antagonized tumour necrosis factor- α -induced NF- κ B transactivation. They concluded that sulforaphane treatment may present a strategy for enhancing the cellular defence mechanisms in skin.

Adverse Immunotoxic Activity

Studies found that oral administration of 3,3'-diindolylmethane (DIM) to neonatal mouse induced multiple immunotoxic effects including decreases in various immune cells (F4/80(+), CD11c(+), CD19(+) and CD3(+) cells) in the spleen, induction of splenic white pulp atrophy, an increase in immune cell apoptosis and decreased expression of various toll-like receptors (TLRs) in the spleen and small intestine (Roh et al. 2011). Also DIM administration led to deterioration of rotavirus-induced intestinal disease and delayed viral clearance in the intestine.

Allergy Problems

Work-related symptoms such as rhinitis, conjunctivitis, asthma and urticaria caused by broccoli

and cauliflower pollen were reported by 44 % of the participants (24/54), of whom all but one had positive skin prick tests for cauliflower-and/or broccoli-pollen/flower extracts, and 58 % (14/24) had positive radioallergosorbent test (RAST) results (Hermanides et al. 2006). Symptoms had developed within the first 2 years in 33 % of the patients. Six patients had to stop or change work.

Other Uses

The antifungal activity of phytoalexins caulilexins A–C against the economically important phytopathogenic fungi *Leptosphaeria maculans*, *Rhizoctonia solani* and *Sclerotinia sclerotiorum* was reported (Pedras et al. 2006).

Comments

Refer also to notes under broccoli—*Brassica oleracea* (Italica Group).

Brassica oleracea (Italica Group)

Scientific Name

Brassica oleracea L. (Italica Group)

Synonyms

Brassica oleracea L. var. *italica* Plenck, *Brassica botrytis* subsp. *italica* Lizg., *Brassica cauliflora* subsp. *simplex* Lizg., *Brassica oleracea* var. *asparagoides* Gmel., *Brassica oleracea* var. *botrytis* subvar. *cymosa* Thell.

Family

Brassicaceae

Common/English Names

Asparagus Broccoli, Broccoli, Calabrese, Cape Broccoli, Heading Broccoli, Green Heading Broccoli, Purple Heading Broccoli, Sprouting Broccoli, Winter Cauliflower

Vernacular Names

Afrikaans: Spruitjes, Spruitkool, Winterblomkool, Winterkool

Albanian: Brokoli

Arabic: Brokli

Brazil: Arroz De Brócolis, Brócolis Americano, Brócolos (Portuguese)

Breton: Brouskaolenn

Bulgarian: Vid Cvetno Sele

Catalan: Broquil

Chinese: Gaai Choi Fa, Qing Hua Cai, Sai Lan Fa (Cantonese), Jie Cai Hua, Lu Hua Cai, Nen Jing Hua Ye Cai, Yang Ye Cai Hua, Yi Da Li Jie Lan, Ying Hua Gan Lan (Mandarin)

Croatian: Kelj-Pupčar, Prokula, Prokulica

Czech: Brokolice, Brukev Brokolice

Danish: Broccoli, Brokkoli

Dhivehi: Burokol

Dutch: Broccoli, Broccoli kiemen, Brocolispruiten

Eastonian: Asparkapsas

Esperanto: Brokolo

Finnish: Parsakaali

French: Brocoli Asperge, Brocoli Branchu, Chou Broccoli

Frisian: Brokolli

Gaelic: Callish Rangagh

German: Braunkohl, Brokkoli, Spargelkohl, Sprossenbrokkoli

Greek: Brókola

Haitian: Bwokoli (Creole)

Hungarian: Brokkoli

Icelandic: Spergilkál

India: Phulagobhi, Phoolagobhee, Fulagobhi (Hindi), Brēākkeāḷi (Malayalam), Brōkāḷi (Marathi)

Indonesian: Brokali

Italian: Broccolo, Cavolo Broccoli, Cavolo Broccolo, Cavolo Romano

Japanese: Burokkorii, Italia-Kanran, Karifurawaa

Korean: Beu Ro Kol Li, Nok-Saek-Kkoch-Yang-Bae-Chu

Latvian: Brokoli

Lithuanian: Brokolis

Macedonian: Brokoli

Malaysia: Brokaoli

Maltese: Brokkli

Norwegian: Bróculo, Brokkoli

Philippines: Brokoli (Cebuano), Broccoli (Iloko)

Polish: Brokul, Brokuly, Kapusta Szparagowa

Portuguese: Brócolis, Brócos, Brócolos, Bróculos

Russian: Brokoli

Serbian: Brokoli

Sicilian: Bròcculu, Ciurettu

Slováština: Brokolica

Slovenčina: Brokolica

Romanian: Broccoli

Provencale: Brokoli

Spanish: Brécol, Brecolera, Brócoli, Bróculi

Swedish: Sparriskål

Thai: Břxkh Kho Lř, Sěung Kláai Gà Hřr

Turkish: Brokoli, Italya Lahanasi

Ukrainian: Brokoli

Vietnamese: Cải Bông Xanh

Agroecology

Broccoli requires a cool, moist subtemperate climate, with average daily temperatures of 15–20 °C. Higher temperatures result in no flower-head production, and too low temperature results in small button heads. The plant is cold tolerant, but is not frost hardy. It thrives best in well-drained, moist, fertile loamy, sandy loam or loamy clay soils, rich organic matter and an alkaline pH of 6–7 with sufficient soil boron. Boron deficiency results in blackened hollow stem.

Edible Plant Parts and Uses

Flowering head consisting of unopened flower buds and fleshy upper portion of the stem is consumed as vegetables. Flower head is divided into smaller bits and can be eaten raw or lightly cooked, steam, microwave and stir-fry and eaten as mixed salads or in pickles. The stems need to be cooked longer. Broccoli is available as quick-frozen vegetables and processed in dried mixtures of soup vegetables.

Botany

Erect, glabrous, annual or biennial herb up to 80 cm tall at the mature vegetative stage, up to 130 cm when flowering with unbranched, waxy stem thickening upwards; a shallow, strongly branched tap root system. Leaves are thick, somewhat leathery, smooth oblong, simple, alternate, lamina blade ovate to oblong, up to 80 cm × 40 cm, undulate or irregularly incised to almost entire, greyish blue to green, shortly petiolate and exstipulate (Plate 1). Inflorescence a terminal panicle raceme up to 70 cm long, the thick, fleshy branched inflorescence begins as a compact slightly dome-shaped head up to 40 cm across (Plates 1, 2 and 3) and loses its compactness as the flower stalk enlarges and flowers open. The inflorescence produces bisexual cross-shaped, tetramerous flowers on 1–2 cm pedicel, with four erect, oblong sepals; four yellow

Origin/Distribution

Broccoli and cauliflower are thought to have evolved in Roman times from wild or primitive cultivated forms of *Brassica oleracea* in the eastern Mediterranean region. A remarkable diversity of cauliflower and broccoli-like vegetables has been developed in Italy.

The leading cauliflower- and broccoli-producing countries in terms of total production (tonnes) are as follows: China, 8,935,000; India, 6,745,000; Spain, 513,783; Mexico, 427,884; Italy, 420,989; France, 364,558; United States, 301,590; Poland, 297,649; Pakistan, 227,591; Egypt, 201,200; United Kingdom, 180,577; Bangladesh, 168,238; Turkey, 162,134; Japan, 152,400; Germany, 144,136; Indonesia, 113,492; Algeria, 105,829; Morocco, 104,569; and Belgium, 99,660 (FAO 2012).

Plate 1 Broccoli leaves and flower head

Plate 2 Harvested broccoli

Plate 3 Close-up of broccoli flower head

obovate, clawed petals; six stamens; superior ovary-2-loculed; and a globose stigma. Fruit a slender, linear silique 5–10 cm×0.5 cm, with a tapering beak 5–15 mm long, dehiscent when dry, 20–40 seeded. Seeds globose, 2–4 mm in diameter, finely reticulate, brown.

Nutritive/Medicinal Properties

Nutrients and Phytochemicals

Nestle (1997) listed the following potentially anticarcinogenic attributes and components of broccoli and other cruciferous vegetables: low fat, low energy, macronutrients, micronutrients, vitamin A, vitamin C, vitamin E, folic acid, selenium, fibre, carotenoids, coumarins, dithiolthiones, flavonoids, glucosinolates, indoles, isothiocyanates, phenols and terpenes.

The proximate nutrient value per 100 g edible portion of raw broccoli (USDA 2012) was reported as follows: water, 89.30 g; energy, 34 kcal (141 kJ); protein, 2.82 g; total lipid, 0.37 g; ash, 0.87 g; carbohydrate, 6.64 g; total dietary fibre, 2.6 g; total sugars, 1.7 g; sucrose, 0.10 g; glucose, 0.49 g; fructose, 0.68 g; lactose, 0.21 g; maltose, 0.21 g; minerals Ca, 47 mg; Fe, 0.73 mg; Mg, 21 mg; P, 66 mg; K, 316 mg; Na, 33 g; Zn, 0.41 mg; Cu, 0.049 mg; Mn, 0.210 mg; Se, 2.5 µg; vitamins vitamin C, 89.2; thiamine, 0.071 mg; riboflavin, 0.117 mg; niacin, 0.639 mg; pantothenic acid, 0.573 mg; vitamin B 6, 0.175 mg; total folate, 63 µg; total choline, 18.7 mg; betaine, 0.1 mg; vitamin A, 623 IU; vitamin A, 31 µg RAE; β-carotene, 361 µg; lutein+zeaxanthin, 1,403 µg; vitamin E (α-tocopherol), 0.78 mg; β-tocopherol, 0.01 mg; γ-tocopherol, 0.17 mg; vitamin K (phylloquinone), 101.6 µg; total saturated fatty acids, 0.039 g; 14:0 (myristic acid), 0.001 g; 16:0 (palmitic acid), 0.029 g; 18:0 (stearic acid), 0.006 g; 20:0 (arachidic acid), 0.002 g; 22:0 (behenic acid), 0.002 g; total monounsaturated fatty acids, 0.011 g; 17:1 (heptadecenoic acid), 0.001 g; 18:1 undifferentiated, 0.010 g; total polyunsaturated fatty acids, 0.038 g; 18:2 undifferentiated (oleic acid), 0.017 g; 18:3 undifferentiated (linolenic acid), 0.021 g; and amino acids tryptophan, 0.033 g; threonine, 0.088 g; isoleucine, 0.079 g; leucine, 0.129 g; methionine, 0.038 g; cystine, 0.028 g; phenylalanine, 0.117 g; tyrosine, 0.050 g; valine, 0.125 g; arginine, 0.191 g; histidine, 0.059 g; alanine, 0.104 g; aspartic acid, 0.325 g; glutamic acid, 0.542 g;

glycine, 0.089 g; proline, 0.110 g; and serine, 0.121 g.

Maximum mean vitamin C (52.9 mg/100 g), β -carotene (0.81 mg/100 g), lutein (0.68 mg/100 g), dl- α -tocopherol content (0.47 mg/100 g) and phenol content (63.4 mg/100 g) were recorded in broccoli (Singh et al. 2007). The following carotenoids were found in broccoli: neoxanthin, neochrome, violaxanthin, luteoxanthin, auroxanthin, lutein-5,6-epoxide, flavoxanthin, lutein and β -carotene (Khachik et al. 1986, 1991). Studies found substantial variation in α -carotene, β -carotene, α -tocopherol, γ -tocopherol and ascorbate contents within and between subspecies of *Brassica oleracea* (50 broccoli and 13 cabbage, kale, cauliflower and Brussels sprouts accessions) (Kurilich et al. 1999). Kale had the highest levels of vitamins, followed by broccoli and Brussels sprouts with intermediate levels and then by cabbage and cauliflower, with comparatively low concentrations. Variability in vitamin content among the broccoli accessions suggested potential health benefits associated with consumption were genotype dependent. Broccoli and other vegetables and fruit were found to contain glucaric acid, the content of which varied from a low of 1.12–1.73 mg/100 g for broccoli and potatoes to a high of 4.53 mg/100 g for oranges (Dwivedi et al. 1990). The predominant glucosinolates in broccoli were 4-methylsulphinylbutyl glucosinolate (glucoraphanin), 3-butenyl glucosinolate (gluconapin) and 3-indolylmethyl glucosinolate (glucobrassicin) (Kushad et al. 1999). Glucoraphanin concentration in broccoli ranged from 0.8 μ mol/g⁻ DW in cv. EV6-1 to 21.7 μ mol/g DW in cv. Brigadier. Concentrations of the other glucosinolates in broccoli varied similarly over a wide range.

Glucosinolates identified in broccoli inflorescences included the following: 3-methylsulphinylpropyl-glucosinolate (glucoiberin), 2-hydroxy-3-butenyl-glucosinolate (progoitrin), 4-methylsulphinylbutyl-glucosinolate (glucoraphanin), 5-methylsulphinylpentyl-glucosinolate (glucoalysyn), 3-butenyl-glucosinolate (gluconapin), 4-hydroxy-3-indolylmethyl-glucosinolate (4-hydroglucobrassicin), 4-pentenyl-glucosinolate (glucobrassicinapin), 3-indolylmethyl-glucosinolate (glucobrassicin), 2-phenylethyl-glucosinolate (gluconasturtin), 4-methoxy-3-indolylmethyl-glucosinolate (4-methoxyglucobrassicin) and 1-methoxy-3-indolylmethyl-glucosinolate (neoglucobrassicin) (Rosa and Rodrigues 2001; Vallejo et al. 2003a, b; Moreno et al. 2006). The predominant glucosinolates in all broccoli cultivars were 4-methylsulphinylbutyl-glucosinolate (glucoraphanin), 3-indolylmethyl-glucosinolate (glucobrassicin) and 1-methoxy-3-indolylmethyl-glucosinolate (neoglucobrassicin) (Rosa and Rodrigues 2001; Vallejo et al. 2003a). A new glucosinolate cinnamoyl derivative 6'-O-trans-(4"-hydroxy cinnamoyl)-4-(methylsulphinyl) butyl glucosinolate was isolated from broccoli florets (Survay et al. 2010). Two glucosinolates, glucoiberin and 3-hydroxy, 4(α -L-rhamnopyranosyloxy) benzyl glucosinolate, were identified in aqueous Broccoli extract (Hashem et al. 2012b). Further, two compounds were isolated after enzymatic hydrolysis of the aqueous extract by myrosinase; one of them was identified as 4-vinyl-3-pyrazolidinone and the second compound (sulphoraphane) 1-isothiocyanate-4-methyl-sulphinyl butane was converted to the most stable form of thiourea (sulphoraphane thiourea).

Total and individual glucosinolate levels varied significantly between seasons, among cultivars and between inflorescences. The cv. 'Shogun' contained the highest total glucosinolate levels (between 35.2 mmol/kg dry weight in primary inflorescences of the early crop and 47.9 mmol/kg in secondary inflorescences of the late crop) (Rosa and Rodrigues 2001). Total and individual glucosinolate levels were generally higher in the late than in the early crop. Similarly total glucosinolates were detected more significantly in the late than in the early season and all broccoli cultivars showed a higher content of indolic glucosinolates than aliphatic glucosinolates (Vallejo et al. 2003a). Broccoli florets were characterized by particularly high glucoraphanin content, 17.95 μ mol/g dry weight on average, which comprised about 50 % of total glucosinolates (Borowski et al. 2008). High individual variation was observed for several bioactive compounds, as well as for DPPH•

and OH[•] radical-scavenging activity. Among glucosinolates, the highest coefficient of variation (CVs) was noted for progoitrin (34.22 %), 4-hydroxyglucobrassicin (27.32 %) and neoglucobrassicin (24.44 %). High CVs were also observed for vitamin C (29.11 %), including dehydroascorbic acid (26.72 %), and for OH[•] (25.76 %) and DPPH (21.77 %) radical-scavenging activities. Smaller variations were found for glucoraphanin (CV = 14.84 %) and polyphenols (CV = 14.95 %). The highest concentration of glucoraphanin occurred in young broccoli seedlings and seeds (Rangkadilok et al. 2002a). The glucoraphanin concentration decreased from the start of seed germination to the flowering stages. The lowest concentration was also found at the flowering stage. A higher concentration of glucoraphanin was detected in the green broccoli heads and flower heads than in other reproductive tissues. Each kilogram of extracted broccoli seed yielded approximately 4.8 g of sulforaphane and 3.8 g of sulforaphane nitrile (Matusheski et al. 2001). Vitamin C was not detected in dormant broccoli seeds, and its content increased with the germination, reaching values ranging from 53 (cv. Nubia) to 64 (cv. Marathon) mg/100 g FW, at the end of the monitored period (14 days) (Pérez-Balibrea et al. 2011). The total glucosinolate content in seeds and 3-day-old sprouts was higher in cv. Marathon (1,005 and 556 mg/100 g FW, respectively); however, cv. Viola sprouts registered the highest glucosinolate content 7 and 14 days after sowing (235 and 208 mg/100 g FW, respectively). Glucoraphanin was the predominant glucosinolate in cv. Nubia and cv. Marathon, whereas glucoiberin was the major glucosinolate in cv. Viola. The flavonoid and total phenolic content was significantly higher in cv. Viola. Also, seeds of this cultivar showed the highest antioxidant capacity (2.7 mg Trolox/g FW) .

Broccoli cvs. was found to have a predominance of 4-(methylsulfinyl)butyl-glucosinolate and 4-(methylthio)butyl-glucosinolate in the head and 2-hydroxy-3-butenyl-glucosinolate as secondary component; other glucosinolates present included allyl-glucosinolate, 3-(methylthio)propyl-glucosinolate, 3-(methylsulfinyl)-propyl- glucosinolate,

3-butenyl- glucosinolate, 4-pentyl- glucosinolate, 2-phenyl-ethyl- glucosinolate and 3-indolyl-methyl- glucosinolate (Carlson et al. 1987). Eight aliphatic glucosinolates, four indole glucosinolates and one aromatic glucosinolate were identified and quantified in the florets of 5 main Chinese broccoli and 143 parent materials (Wang et al. 2012b). Glucoraphanin, glucobrassicin, 4-methoxyglucobrassicin and neoglucobrassicin were present in all samples. The anticancer glucoraphanin concentration ranged from 0.06 to 24.17 $\mu\text{mol/g}$ in pure lines and from 1.57 to 5.95 $\mu\text{mol/g}$ in commercial cultivars. The progoitrin concentration in commercial cultivars varied from 1.77 to 6.07 $\mu\text{mol/g}$ with a mean value of 3.20 $\mu\text{mol/g}$. Significant variations were observed in the concentration of individual glucosinolates and in each class of glucosinolates among broccoli populations.

Phenolics found in broccoli inflorescences included: caffeoylquinic derivatives (3-*O*-caffeoylquinic (neochlorogenic acid), 5-*O*-caffeoylquinic (chlorogenic acid)); sinapic derivatives (1,2-disinapoylgentiobiose, 1-sinapoyl-2-feruloylgentiobiose, 1,2,2-trisinapoylgentiobiose, 1,2-disinapoyl-2-feruloylgentiobiose, 1-sinapoyl-2,2-diferuloylgentiobiose, 1,2,2-trisinapoylgentiobiose); and feruloyl acid derivatives (1,2-diferuloylgentiobiose) (Vallejo et al. 2003b). The main hydroxycinnamic acids (sinapic, ferulic, *p*-coumaric and caffeic acids) were isolated from broccoli and broccolini by capillary zone electrophoresis (Lee et al. 2011). Eight minor glucosinolates, viz., 1-methylpropyl-glucosinolate, 2-methylpropyl-glucosinolate, 2-methylbutyl-glucosinolate, 3-methylbutyl-glucosinolate, *n*-pentyl-glucosinolate, 3-methylpentyl-glucosinolate, 4-methylpentyl-glucosinolate and *n*-hexyl-glucosinolate, were identified in crude sample extracts of broccoli, cauliflower and rocket salad (Lelario et al. 2012). The occurrence of these glucosinolates belonging to the saturated aliphatic side chain families C4, C5 and C6, presumably formed by chain elongation of leucine, homoleucine and dihomoleucine as primary amino acid precursors, was described. Two nitrogenous compounds were uridine and uridine 9-acetate isolated from the ethyl acetate broccoli extract (Hashem et al. 2012a).

A large number of hydroxycinnamic acid esters of kaempferol and quercetin glucosides were characterized in broccoli inflorescences (Vallejo et al. 2004b). The structures of the flavonoid glycosides were analyzed after alkaline hydrolysis and were identified as 3-sophorose/sophorotriose-7-glucoside/sophorose of kaempferol, quercetin and isorhamnetin. Additionally, several less complex glucosides based on the same aglycones were identified. Flavonoids acylated with hydroxycinnamic acid derivatives included sinapoyl/feruloyl gentiobioside compounds; 1,2-disinapoylgentiobiose; 1-sinapoyl-2-feruloylgentiobiose; 1,2-diferuloylgentiobiose; 1,2,2'-trisinapoylgentiobiose; 1,2'-disinapoyl-2-feruloylgentiobiose; 1-sinapoyl-2,2'-diferuloylgentiobiose; 1,2,2'-trisinapoylgentiobiose; and 1,2,2'-triferuloylgentiobiose. Some of the flavonoids identified included: quercetin-3-*O*-sophorotriose-7-*O*-glucoside; quercetin-3-*O*-sophorose-7-*O*-glucoside; quercetin-3-*O*-sophorotriose-7-*O*-sophorose; kaempferol-3-*O*-sophorotriose-7-*O*-glucoside; kaempferol-3-*O*-sophorotriose-7-*O*-sophorose; kaempferol-3-*O*-sophorose-7-*O*-glucoside; isorhamnetin-3-*O*-sophorotriose-7-*O*-glucoside; kaempferol-3-*O*-sophorose-7-*O*-sophorose; isorhamnetin-3-*O*-sophorotriose-7-*O*-sophorose; quercetin-3,7-di-*O*-glucoside; quercetin-3-*O*-glucoside-7-*O*-sophorose; kaempferol-3,7-di-*O*-glucoside; kaempferol-3-*O*-glucoside-7-*O*-sophorose; isorhamnetin-3,7-di-*O*-glucoside; isorhamnetin-3-*O*-glucoside-7-*O*-sophorose; quercetin-3-*O*-sophorose; kaempferol-3-*O*-sophorose; quercetin-3-*O*-glucoside; kaempferol-3-*O*-glucoside; quercetin-3-*O*-(feruloyl/sinapoyl)-sophorotriose-7-*O*-glucoside; and kaempferol-3-*O*-(caffeoyl/sinapoyl)-sophorotriose-7-*O*-sophorose. Using liquid chromatography-photodiode array-solid-phase extraction-nuclear magnetic resonance/mass spectrometry, five related glycosylated phenolic acids were identified in broccoli: 1,2-di-*O*-*E*-sinapoyl- β -gentiobiose; 1-*O*-*E*-sinapoyl-2-*O*-*E*-feruloyl- β -gentiobiose; 1,2-di-*O*-*E*-feruloyl- β -gentiobiose; 1,2,2'-tri-*O*-*E*-sinapoyl- β -gentiobiose; and 1,2'-di-*O*-*E*-sinapoyl-2-*O*-*E*-feruloyl- β -gentiobiose (Moco and Vervoort 2012).

Major volatile components identified in broccoli included nonanal, octanol, 3-methylthiobutyl cyanide, 2-phenylethyl cyanide and 2-phenylethyl isothiocyanate (Buttery et al. 1976). The major volatiles identified in blanched, cooked broccoli florets were: n-pentanal, 3-methyl-2-pentanone, n-hexanal, n-heptanal, ethyl acetate, cyclopentanecarboxaldehyde, 3-methylbutanal, 3-butenitrile, 2-methylbutanal, dimethyl trisulfide and dimethyl disulfide (Kallio et al. 1999). In broccoli and cabbage, exogenous methyl jasmonate induced the emission of the volatiles sesquiterpene (*E,E*)- α -farnesene, the homoterpene (*E*)-4,8-dimethyl-1,3,7-nonatriene (DMNT) and green leaf volatiles (*Z*)-3-hexenyl acetate and octanal (Ibrahim et al. 2005). Volatiles produced by the action of endogenous cystine lyase on S-methyl-cysteine sulfoxide present in Broccoli florets showed three sulphur components: dimethyl disulphide, dimethyl trisulphide and 3,5-dimethyl-1,2,4-trithiolane (Motawea et al. 2010). Four isothiocyanate compounds were also present. Cystine lyase enzymatic fission of endogenous myrosinase yielded the unsaturated glucosinolates ethenyl isothiocyanate and allyl isothiocyanate, together with the saturated 4-methylthiobutyl isothiocyanate (erucin) and the aromatic 2-phenylethyl isothiocyanate (PEITC).

Glucosinolates found in broccoli purchased from local Singapore markets were in nmol/g wet weight: glucoraphanin, 522 nmol; gluconasturtin, NQ (not quantified); sinigrin, NQ; glucobrassicin, 4,250 nmol; 4-hydroxy glucobrassicin, 198 nmol; 4-methoxy glucobrassicin, 432 nmol; 1-methoxy glucobrassicin, 1,100 nmol; glucoiberin, 40.9; progoitrin (or epiprogoitrin), NQ; glucoalyssin, 18.4 nmol; gluconapoleiferin, NQ; gluconapin, NQ; glucobrassicinapin, NQ; glucoerucin, NQ; 7-methylthioethyl, NQ; 8-methylthioethyl, NQ; total glucosinolates, 6,570 nmol; and glucobrassicins, 91 % of total glucosinolates (Hecht et al. 2004). Glucobrassicins (glucobrassicin, 1-methoxyglucobrassicin, 4-methoxyglucobrassicin and 4-hydroxyglucobrassicin), precursors to indole-3-carbinols, were the predominant glucosinolates in seven of the nine vegetables (including cauliflower and broccoli) studied, accounting for 70.0–93.2 % of

all glucosinolates. Six individual desulfo-glucosinolates, including progoitrin, glucoraphanin, sinigrin, gluconapin, glucobrassicinapin and glucobrassicin, were commonly identified in the flower head of 95 Korean broccoli accessions (Lee et al. 2012). The total glucosinolate contents varied from 4.2 to 29 $\mu\text{mol/g DW}$, and the glucoraphanin (1.6–13.9 $\mu\text{mol/g DW}$) was confirmed as a major constituent in the total glucosinolate profile; in contrast, progoitrin was only detected in 13 accessions. Glucobrassicinapin, glucoraphanin, glucobrassicin, and gluconapin were the major glucosinolates.

Two novel glucosinolates identified as 2-mercaptomethyl sulfinyl glucosinolate [(Z)-4-(methylsulfinyl)-N-(sulfooxy)-2-((2'S,3'R,4'S,5'S,6'R)-3',4',5'-trihydroxy-6'(hydroxymethyl)-2'-mercapto tetrahydro-2H-pyran-2-yl) butane amide] and (Z)-1-((2S,5S)-5-hydroxytetrahydro-2H-pyran-2-ylthio)-2-(1H-indol-3-yl) ethylidene amino sulfate along with one known cinnamoyl [6'-O-trans-(4"-hydroxy cinnamoyl)4-(methylsulphanyl)butyl glucosinolate] were isolated from broccoli florets (Survay et al. 2012).

Six organoselenium compounds including selenium analogues of known myrosinase-derived *Brassica* volatiles, 4-(methylseleno)butanenitrile, 5-(methylseleno) pentanenitrile, 3-(methylseleno)propylisothiocyanate, 4-(methylseleno) butylisothiocyanate and 5-(methylseleno) pentylisothiocyanate, were identified in the pentane/ether extracts of broccoli and cauliflower florets and roots of forage rape, all obtained from plants treated with sodium selenate (Matich et al. 2012). LC-MS analysis of ethanolic extracts identified three selenoglucosinolates: 3-(methylseleno) propylglucosinolate (glucoselenoiberberin), 4-(methylseleno) butylglucosinolate (glucoselenoerucin) and 5-(methylseleno)pentylglucosinolate (glucoselenoberteroin). In broccoli, concentrations of the selenoglucosinolates and their aglycones (mainly nitriles) were up to 60 and 1,300 %, respectively, of their sulphur analogues.

A DNA topoisomerase I with an 80 kDa monomer was isolated from broccoli (Kieber et al. 1992). Three isoforms (a, b and c) of cystine lyase were found in broccoli inflorescence tissues

(Ukai and Sekiya 1999). Cystine lyase b, the most abundant isoform, had a molecular weight of 160,000 and composed of four identical subunits with a molecular weight of 40,000. The purified cystine lyase b utilized l-cystine and S-alkyl l-cysteine sulfoxide as substrates. Cystine lyase a and b were localized in cytosolic and/or vacuole fraction. Three peroxidase (POD) isoenzymes were purified from a soluble extract of broccoli stems (Thongsook and Barrett 2005). The neutral and basic PODs had molecular masses of approximately 43 kDa, and the acidic POD had a molecular mass of 48 kDa. All three of the purified isoenzymes were glycosylated. Two cDNAs encoding proteins with homocysteine S-methyltransferase (HMT) activity were isolated from broccoli and functionally characterized (Lyi et al. 2007). While one gene product exhibited only HMT activity, the other displayed both HMT and selenocysteine Se-methyltransferase (SMT) activities, indicating the gene had evolved to include an additional function in sulfur/selenium accumulating species. The presence of acidic metalloproteases, serine proteases and cysteine proteases was found in broccoli florets (Rossano et al. 2011). Post-harvest senescence of broccoli florets was characterized by decrease in protein and chlorophyll contents and increase of protease activity, particularly cysteine protease. Pheophytinase (PPH) activity in broccoli florets increased concomitantly with a decline in chlorophyll *a* and *b*, suggesting that PPH may be involved in chlorophyll degradation (Aiamla-or et al. 2012). PPH activity in broccoli flowers treated with a UVB dose of 19 kJ/m^2 was repressed for the first 2 days of storage at 15 °C, whereas it increased gradually with senescence of broccoli florets. UVB treatment delayed upregulation of chlorophyll-degrading enzyme chlorophyllase genes resulting in the suppression of floret yellowing in stored broccoli.

Brassica plants (e.g., broccoli and cauliflower) contain substantial quantities of isothiocyanates (mostly in the form of their glucosinolate precursors), some of which (e.g., sulforaphane or 4-methylsulfinylbutyl isothiocyanate) are very potent inducers of phase 2 enzymes (Fahey et al. 1997). Three-day-old sprouts of cultivars of

certain crucifers including broccoli and cauliflower were found to contain 10–100 times higher levels of glucoraphanin (the glucosinolate of sulforaphane) than do the corresponding mature plants. Broccoli seedlings cultivated using a 30/15 °C (day/night) temperature regime had significantly higher glucosinolate levels (measured at six consecutive days postemergence) than did sprouts cultivated at lower temperatures (22/15 and 18/12 °C). Both higher (33.1 °C) and lower (11.3 °C) constant temperatures induced higher glucosinolate levels in sprouts grown to a uniform size (Pereira et al. 2002). Glucosinolate levels were highest in cotyledons and lowest in roots of sprouts dissected both early and late in the 11-day developmental span investigated. Nongerminated seeds have the highest glucosinolate levels and concordantly greater induction of mammalian phase 2 detoxication enzymes. Levels declined as sprouts germinated and developed, with consistently higher glucosinolate content in younger developmental stages, independent of the temperature regime. Temperature stress or its associated developmental anomalies induced higher glucosinolate levels, specific elevations in glucoraphanin content and parallel induction of phase 2 chemoprotective enzymes. Pérez-Balibrea et al. (2008) found broccoli (flower head) to be a rich source of phytochemicals (glucosinolates and phenolic compounds) and micronutrients (vitamins and minerals), but germinated broccoli sprouts were found to contain much higher levels (10–100 times) of aliphatic (glucoraphanin) and indolic glucosinolates than the inflorescences. Broccoli sprouts grown in the light were found to have much higher concentrations of vitamin C (by 83 %), glucosinolates (by 33 %) and phenolic compounds (by 61 %) than those grown in the dark. Among the different organs studied (seeds, cotyledons, stems and roots), the cotyledons contained the highest levels of bioactive compounds, while the roots contained the lowest. Glucosinolate concentration in broccoli sprouts was strongly influenced by germination, causing a rapid increase during the first 3 days after sowing, and decreasing afterwards (Pérez-Balibrea et al. 2010). Fertilization with potassium sulphate 15,

30 and 60 mg/l at 9 and 12 days after sowing enhanced glucosinolate content.

Using liquid chromatography–mass spectrometry, Maldini et al. (2012) validated the presence of eight glucosinolates: glucobrassicin, glucoraphanin, glucoiberin, glucoerucin, progoitrin, gluconapin, sinigrin and glucocheirolin in broccoli sprouts with an overall recovery of 99 % for the eight glucosinolates. Using high-performance liquid chromatography–electrospray ionization–tandem mass spectrometry, Tian et al. (2005) quantified ten individual glucosinolates in broccoli, broccoli sprouts, Brussels sprouts and cauliflower. Detection limits for glucoiberin, sinigrin, progoitrin, glucoerucin and glucotropaeolin were 1.75, 1.38, 1.36, 0.6 and 0.63 pmol, respectively. Aliphatic glucosinolates (glucoraphanin, glucoiberin and glucoerucin) and a group of indole glucosinolates including 4-hydroxy-glucobrassicin and folates preformed in broccoli seeds were detected in broccoli sprouts (Rychlik and Adam 2008). In the early stage of sprouting, a reduction (approx. 20 %) of the aliphatic glucosinolates was determined, and levelling off up to the 12th day while 4-hydroxy-glucobrassicin declined continuously, three minor indole derivatives increased steadily, but remained at a comparatively low level. During germination, the contents of total folates increased to 72 µg/100 g fresh mass and 546 µg/100 g dry mass on the 4th day decreased again to 13 µg/100 g fresh mass until the 8th day of germination and remained at this low level. 5-Methyltetrahydrofolate was found as the predominant vitamer at each stage. Vitamin C, phenolic compounds, and glucosinolates in these purple sprouting varieties, EEP (Extra Early), EP (Early) and LP (Late) grown in Spain, were higher than in traditionally grown green broccolis and other purple broccolis grown under different climate conditions (Rodríguez-Hernández et al. 2012).

The following acylated anthocyanins were identified in broccoli sprouts: cyanidin-3-*O*-diglucoside-5-*O*-glucoside acylated and double acylated with *p*-coumaric, sinapic, caffeic, ferulic or sinapic acids, with at least three predominant anthocyanins isomers of cyanidin 3-*O*-(acyl) diglucoside-5-*O*-glucoside, cyanidin 3-*O*-(acyl 1)

(acyl 2)diglucoside-5-*O*-glucoside and cyanidin 3-*O*-(acyl 1)(acyl 2)diglucoside-5-*O*-(malonyl) glucoside (Moreno et al. 2010). The early purple sprouting broccoli sprouts ('Viola') showed significantly higher concentrations of cyanidin 3-*O*-(sinapoyl) diglucoside-5-*O*-glucoside, cyanidin 3-*O*-(feruloyl) diglucoside-5-*O*-glucoside, cyanidin 3-*O*-(sinapoyl) (sinapoyl) diglucoside-5-*O*-glucoside and cyanidin 3-*O*-(sinapoyl) (feruloyl) diglucoside-5-*O*-(malonyl) glucoside. The total concentration of anthocyanins identified in 'green head' broccoli cultivars (Marathon, Nubia) and the green variety-for-sprouts (Intersemillas) was similar (0.23–0.29 mg/100 g) and significantly lower than that in cv. 'Viola' (0.64 mg/100 g).

Processing/Storage and Broccoli Phytochemicals

Broccoli offers many health-promoting properties owing to its content of antioxidant and anticarcinogenic compounds (Mahn and Reyes 2012). The concentration and bioavailability of polyphenols, glucosinolates, sulforaphane and selenium depend on plant biochemistry, cultivation strategy and type of processing. Steaming and drying had been reported to result in an apparent increment of sulforaphane content as well as antioxidant activity, most likely due to an increase of the extractability of antioxidants and sulforaphane. Freezing and boiling were found to diminish polyphenols concentration, mainly due to volatilization and leaching into the cooking water. The two main flavonol glycosides quercetin 3-*O*-sophoroside and kaempferol 3-*O*-sophoroside and three minor glucosides of quercetin and kaempferol, namely, isoquercitrin, kaempferol 3-*O*-glucoside and a kaempferol diglucoside, were identified in broccoli florets (Price et al. 1998). The sophorosides of quercetin and kaempferol were present in raw florets at a level of 65 and 166 mg/kg fresh weight, respectively. The total content of quercetin and kaempferol glycosides expressed as aglycone was 43 and 94 µg/g fresh weight, respectively, and these agree with other recently published data. During

the cooking process, only 14–28 % of the individual glucosides were retained in the cooked tissue, the remainder being largely leached into the cooking water with only a small loss attributed to the formation of the respective aglycones. Studies showed a general decrease in the levels of glucosinolates, phenolic compounds, and vitamin C compounds except for mineral nutrients which were stable under all microwave cooking conditions (López-Berenguer et al. 2007). Vitamin C showed the greatest losses mainly because of degradation and leaching, whereas losses for phenolic compounds and glucosinolates were mainly due to leaching into water. In general, the longest microwave cooking time and the higher volume of cooking water should be avoided to minimize losses of nutrients. Studies showed that during stir-frying of broccoli, phenolics and vitamin C were more affected than glucosinolates and minerals (Moreno et al. 2007). Stir-fry cooking with extra virgin olive, soybean, peanut or safflower oil did not reduce the total glucosinolate content of the cooked broccoli compared with that of the uncooked sample. The vitamin C content of broccoli stir-fried with extra virgin olive or sunflower oil was similar to that of the uncooked sample, but greater than those samples stir-fried with other oils.

The predominant sinapic acid derivatives in broccoli inflorescence after cooking were identified as 1,2,2'-trisinapoylgentiobiose and 1,2'-disinapoyl-2-feruloylgentiobiose; 1,2-diferuloylgentiobiose and 1-sinapoyl-2,2'-diferuloylgentiobiose were also identified (Vallejo et al. 2003c). The results showed large differences in flavonoid and hydroxycinnamoyl derivative contents in broccoli among the four cooking treatments. Clear disadvantages were detected when broccoli was microwaved, namely, high losses of flavonoids (97 %), sinapic acid derivatives (74 %) and caffeoylquinic acid derivatives (87 %). Conventional boiling led to a significant loss of flavonoids (66 %) from fresh raw broccoli, while high-pressure boiling caused considerable leaching (47 %) of caffeoylquinic acid derivatives into the cooking water. In contrast, steaming had minimal effects, in terms of loss, on both flavonoid and hydroxycinnamoyl derivative contents.

Isothiocyanate content in broccoli juice treated by freezing, pasteurization and high pressure was found to range from 1.45 to 10.68, 1.94 to 5.54 and 1.87 to 11.27 $\mu\text{mol/l}$, respectively (Totušek et al. 2011). Sulforaphane content in broccoli juice treated by freezing, pasteurization and high pressure was found to range from 7.77 to 14.25, 8.87 to 15.67 and 8.24 to 14.64 $\mu\text{g/ml}$, respectively.

Production of nitrile during hydrolysis of unheated broccoli cultivars varied among cultivars from 91 to 52 % of hydrolysis products (Pinnacle>Marathon>Patriot>Brigadier) (Wang et al. 2012a). Boiling and microwave heating caused an initial loss of nitrile, with a concomitant increase in sulforaphane, followed by loss of sulforaphane, all within a minute. In contrast, steaming enhanced sulforaphane yield between 1 and 3 minutes in all but cv. Brigadier. The data indicated that steaming for 1–3 minutes provided less nitrile and more sulforaphane yield from a broccoli meal. Processing was found to reduce the glucosinolate content of broccoli, among other aspects due to thermally induced degradation (Hanschen et al. 2012). In broccoli sprouts, methylsulfinylalkyl glucosinolates were more susceptible to degradation at high temperatures, whereas methylsulfinylalkyl glucosinolates were revealed to be more affected in aqueous medium under alkaline conditions. Besides small amounts of isothiocyanates, the main thermally induced breakdown products of sulfur-containing aliphatic glucosinolates were nitriles. Although nitriles were most rapidly formed at comparatively high temperatures under dry heat conditions, their highest concentrations were found after cooking in acidic medium, conditions being typical for domestic processing.

The highest content of glucoraphanin and quinone reductase activity was found in broccoli florets stored under controlled atmosphere storage of 21 % O_2 + 10 % CO_2 at 5 °C (Xu et al. 2006). These conditions were able to maintain the visual quality, glucoraphanin content and quinone reductase activity of the broccoli florets for 20 days.

Vapor cooking of fresh broccoli did not generate 2,3,5-trithiahexane (TTH), but cutting broccoli into pieces followed by cooking in water

allowed the detection of this odorant (Spadone et al. 2006). Cutting broccoli activates cysteine sulfoxide lyase transforming methylcysteine sulfoxide into methylsulfenic acid, which upon heating gives rise to dimethylsulfide and dimethyl trisulfide that react to TTH. The formation of TTH was enhanced upon frozen storage of cut broccoli pieces for a few weeks. Visual quality of broccoli heads declined significantly with increasing temperature and length of storage, caused primarily by increasing yellowing and loss of turgor (Winkler et al. 2007). Glucoraphanin, quercetin and kaempferol contents were not significantly affected by storage and marketing temperature and time. The results suggested that current transport and marketing practices were not likely to have a deleterious effect on the levels of aliphatic glucosinolates and flavonols in broccoli.

Studies showed significant differences among broccoli and cauliflower cultivar groups for the glucosinolate proportions as well as the contents of health-promoting and flavour-influencing alkyl, alkenyl and indole glucosinolates (Schonhof et al. 2004). These differences impacted on differences in sensory properties such as colour; taste properties such as bitter and sweet; and flavour such as green/grassy, spicy, broccoli-like, cabbage-like, cauliflower-like, kohlrabi-like, leek-like and mouthfeel pungent. Consumers were seen to prefer cultivars with a bright colour, a lower level of bitter-tasting glucosinolates (alkenyl and indole glucosinolates) and a higher sucrose content.

Endogenous folate poly- γ -glutamates in broccoli florets were found predominantly as hepta- and hexa- γ -glutamates (Munyaka et al. 2009). Crushing raw broccoli, acidification and LTLT (low temperature long time, 60 °C/40 minutes) blanching enhanced folate deconjugation, resulting in monoglutamate, di- and tri- γ -glutamates. Compared to other treatments, HTST (high temperature short time, 90 °C/4 minutes) blanching performed prior to crushing resulted in the highest concentration of long-chain poly- γ -glutamates. Acidification combined with LTLT blanching decreased folate poly- γ -glutamates stability, whereas HTST blanching combined

with different sequences of blanching and crushing did not affect folate poly- γ -glutamates stability. It was concluded that crushing (prior to heating), acidification and blanching could be strategically applied to increase the folate monoglutamate content of broccoli. Crushing of raw broccoli resulted in significant poly- γ -glutamate profile changes in broccoli, indicating γ -glutamyl hydrolase catalyzed hydrolysis (Munyaka et al. 2010). During treatments at 25–140 °C, folate retention was higher at 80 and 100 °C than at the other temperatures. A similar trend in thermal stability was observed for folates, vitamin C, total phenols and Trolox equivalent antioxidant capacity (TEAC) value, an indication that conditions that resulted in endogenous antioxidants degradation might also result in folate degradation.

Green colour of broccoli florets was retained under N₂ flow (<0.01 % O₂ and <0.25 % CO₂) and no flow (down to 1.3 % O₂ and up to 30 % CO₂), but these same conditions led to increased sour and sulfurous odors of the fresh product (Hansen et al. 1993). The relative concentration of ethanol, 3-hydroxy-2-butanone, and 2,3-butanediol increased, and C₅–C₇ aldehydes and alcohols decreased in the cooked broccoli which was stored fresh under N₂ or no flow conditions as compared to fresh samples and samples stored under air flow (20.5 % O₂ and <0.5 % CO₂), or restricted air flow (down to 17.2 % O₂ and up to 3.7 % CO₂). Schonhof et al. (2007) found elevated atmospheric CO₂ concentration had a differing effect on individual glucosinolates and glucosinolate groups in broccoli grown in the green house. Total glucosinolate content increased at elevated atmospheric CO₂ concentration as a result of a strong increase in both methylsulphinyllalkyl glucosinolates glucoraphanin and glucoiberin. In contrast, indole glucosinolates simultaneously decreased, predominantly because of a reduction of glucobrassicin and 4-methoxy-glucobrassicin contents. Elevated CO₂ concentration increased photochemical quenching coefficient values in broccoli leaves by up to 100 and 89 % in heads, while glucose and sucrose in leaves increased by about 60 % (Krumbein et al. 2010). Further, in broccoli heads, elevated CO₂ concentration induced

approximately a twofold increase in concentrations of three fatty acid-derived C(7) aldehydes ((*E*)-2-heptenal, (*E,Z*)-2,4-heptadienal and (*E,E*)-2,4-heptadienal), two fatty acid-derived C(5) alcohols (1-penten-3-ol, (*Z*)-2-pentenol), and two amino acid-derived nitriles (phenyl propanenitrile, 3-methyl butanenitrile). Contrariwise, concentrations of the sulfur-containing compound 2-ethylthiophene and C(6) alcohol (*E*)-2-hexenol decreased. Finally, elevated CO₂ concentration increased soluble sugar concentrations due to enhanced photochemical activity in leaves and heads, which may account for the increased synthesis of volatiles. Both applied modified atmospheres (1 % O₂ + 21 % CO₂; 8 % O₂ + 14 % CO₂) provided by two different microperforated biaxial-oriented polypropylene films maintained aliphatic glucosinolates in cauliflower florets, whereas in broccoli florets, the aliphatic glucosinolate concentration decreased slightly in each modified atmosphere (Schreiner et al. 2007). In addition, total indole glucosinolate concentration for both broccoli and cauliflower florets was maintained. Thus, to simultaneously maintain glucosinolates and external appearance as well as to prevent off-odor, a modified atmosphere of 1 % O₂ + 21 % CO₂ provided a suitable environment for storage of *Brassica* floret medley for up to 7 days at 8 °C. Rangkadilok et al. (2002b) found the best method for preserving glucoraphanin concentration in broccoli heads after harvest was storage of broccoli in modified atmosphere packaging treatments and refrigeration at 4 °C. Such condition maintained the glucoraphanin concentration for at least 10 days and also maintained the visual quality of the broccoli heads.

The organosulfur chemicals, namely, glucosinolates and the S-methyl cysteine sulfoxide, found in broccoli (Stoewsand 1995; Vasanthi et al. 2009) in concert with other constituents such as vitamins E, C and K and the minerals such as iron, zinc and selenium and the polyphenols, namely, kaempferol, quercetin glucosides and isorhamnetin, were reported to be responsible for various health benefits of broccoli (Vasanthi et al. 2009). Thus, broccoli consumption had been reported to mediate a variety of functions including providing

antioxidants, regulating enzymes and controlling apoptosis and cell cycle. Thus, the cancer chemopreventive effects of *Brassica* vegetables (like broccoli) that had been shown in human and animal studies may be due to the presence of both types of sulfur-containing phytochemicals (i.e., certain glucosinolates and S-methyl cysteine sulfoxide) (Stoewsand 1995). The cancer protective effect of cruciferous vegetables had been attributed to the presence of isothiocyanates, and sulforaphane, present in broccoli and broccoli sprouts, was by far the most extensively studied (Juge et al. 2007; Clarke et al. 2008). Sulforaphane had proved to be an effective chemoprotective agent in cell culture, carcinogen-induced, and genetic animal cancer models, as well as in xenograft models of cancer. These protective effects of sulforaphane involved multiple mechanisms activated in response to sulforaphane, including suppression of cytochrome P450 enzymes, induction of apoptotic pathways, suppression of cell cycle progression and inhibition of angiogenesis and antiinflammatory activity. Sulforaphane from broccoli had been reported to be an important potent inducer of cytoprotective proteins (also known as phase 2 enzymes) and to act as antioxidants with a dual protective role by (i) scavenging hazardous oxidants directly and instantaneously and (ii) inducing cytoprotective enzymes involved in the detoxification of carcinogens in carcinogenesis (Dinkova-Kostova and Talalay 2008).

Antioxidant Activity

Studies found that the antioxidant capacity of hydrophilic extracts of eight broccoli genotypes ranged from 65.8 to 121.6 μmol Trolox equivalents (TE)/g of tissue and the capacity of lipophilic extracts ranged from 3.9 to 17.5 μmol TE/g using the oxygen radical absorbance capacity (ORAC) assay (Kurilich et al. 2002). Ascorbic acid and flavonoid content of the hydrophilic extracts did not account for the total variation in antioxidant capacity of those extracts, suggesting either the presence of other antioxidant components that have yet to be identified or that the

known antioxidants are producing synergistic effects. The carotenoids did correlate with antioxidant capacity of the lipophilic extracts and accounted for the majority of the variability in that fraction. Studies in noncellular assay systems indicated that broccoli extracts possessed a high capacity for scavenging free radicals or interrupting free radical reactions (Kurilich et al. 2003). Broccoli extracts were also found to protect against reactive oxygen species in HepG2 cells using the dichlorofluorescein–diacetate assay. In HepG2 cells, the level of protection against AAPH (2,2'-azobis (2-amidinopropane) dihydrochloride)-induced reactive oxygen species differed among broccoli genotypes tested. It was concluded that the HepG2 cell assay provided more information about the antioxidative lipid-soluble fraction than the commonly reported ORAC assay. Total antioxidant activity (as determined by ferric reducing antioxidant power) of North Indian broccoli cultivars ranged from 2.05 to 3.56 μmol Trolox/g fresh weight (Kaur et al. 2007). Free radical scavenging activity, as estimated by 2, 2-diphenyl-1-picrylhydrazyl, ranged from 57 to 74 %. Free phenolics ranged from 19.60 to 41.40 mg/100 g fresh weight and on an average constituted 73 % of total extractable phenolics. There was strong positive correlation between free phenolics and antioxidant activity.

For lipophilic broccoli extracts, oxygen radical absorbance capacity (ORAC-L) correlated with inhibition of cellular oxidation of dichlorofluorescein (dichlorofluorescein-L, $R^2=0.596$) (Eberhardt et al. 2005). Also, DNA damage in the presence of the lipophilic extract was negatively correlated with both chemical and cellular measures of antioxidant activity as measured by ORAC-L ($R^2=-0.705$) and dichlorofluorescein-L ($R^2=-0.671$), respectively. However, no correlations were observed for hydrophilic (–H) broccoli extracts, except between polyphenol content and ORAC (ORAC-H; $R^2=0.778$). Inhibition of cellular oxidation by hydrophilic extracts (dichlorofluorescein-H) and ORAC-H was approximately 8- and 4-fold greater than dichlorofluorescein-L and ORAC-L, respectively. Studies showed that steam processing of broccoli elevated the total ORAC (hydrophilic, lipophilic)

value by 2.3-fold (Roy et al. 2009). The hydrophilic part of a steam-processed broccoli had a significant reduction of 2,2'-azobis [2-amidinopropane] dihydrochloride (AAPH)-induced intracellular ROS level in comparison to that of fresh counterpart. Total phenolic content and total flavonoid content also increased in steam-processed broccoli.

The chloroform and ethanol extracts of broccoli florets showed 100 % antioxidant activity in the DPPH assay at 10 mg/1 ml concentration resembling that of vitamin C (ascorbic acid), and the crude extract gave 90.7 % (Motawea et al. 2010). Two novel glucosinolates identified as 2-mercaptomethyl sulfinyl glucosinolate (1) and (Z)-1-((2S,5S)-5-hydroxytetra-hydro-2H-pyran-2-ylthio)-2-(1H-indol-3-yl) ethylidene amino sulfate (2) and a known cinnamoyl [6'-O-trans-(4"-hydroxy cinnamoyl)4-(methylsulphonyl)butyl glucosinolate] (3) isolated from broccoli florets exhibited antioxidant activity (Survay et al. 2012). Compound 1 exhibited scavenging activity against DPPH with an inhibitory concentration IC₅₀ of 20 mM, whereas compound 3 was a weak antioxidant when compared to the standard quercetin (5 mM) as a positive control. Total phenolic content (TPC), total flavonoid content (TFC) and total glucosinolate content (TGsC) were almost higher in Calabrese cultivar than Southern star cultivar (Naguib et al. 2012). Calabrese cultivar showed higher 1, 1-diphenyl-2-picrylhydrazyl DPPH scavenging activity with IC₅₀ value of 16.56 µg/ml compared to Southern star 19.42 µg/ml. Additionally, Calabrese showed higher chelating power (75.36 µg/ml) than Southern star (72.43 µg/ml) at 30 µg/ml when the organic fertilizer was applied. The results indicated that there is a good margin for enhancing antioxidant compounds of broccoli for economic production using organic fertilization. Studies showed that combined hot air and UVC treatment of minimally processed broccoli may enhance protection against oxidative molecules not only by increasing levels of phenolics and ascorbic acid but also by enhancing the activity of enzymes (catalase and ascorbate peroxidase) involved in removing reactive oxygen species (Lemoine et al. 2010).

The major phenolic compounds in broccoli, two flavonol glycosides (quercetin 3-O-sophoroside and kaempferol 3-O-sophoroside) and four hydroxycinnamic acid esters (1,2'-disinapoyl-2-feruloyl gentiobiose, 1-sinapoyl-2-feruloyl gentiobiose, 1,2,2'-trisinapoyl gentiobiose and 1,2-disinapoyl gentiobiose), were exhibited antioxidant activity in the Trolox C equivalent antioxidant capacity (TEAC) and inhibition of iron/ascorbate-induced lipid peroxidation of phosphatidyl choline vesicle assays (Plumb et al. 1997). In the aqueous phase TEAC assay, the two flavonol glycosides were less active than their respective aglycones. TEAC values for the hydroxycinnamic acid esters were less than the sum of their constituent hydroxycinnamic acids on a molar basis. Quercetin 3-O-sophoroside was a potent inhibitor of lipid peroxidation, in contrast to kaempferol 3-O-sophoroside. The hydroxycinnamic acid esters were highly effective at preventing lipid damage with the exception of 1,2,2'-trisinapoyl gentiobiose.

Anticancer Activity (Refer Also to Notes Under B. oleracea (Botrytis Group))

Organic isothiocyanates occurring in *Brassica* vegetables had been reported to block the production of tumours induced in rodents by diverse carcinogens (polycyclic aromatic hydrocarbons, azo dyes, ethionine, N-2-fluorenylacetamide and nitrosamines) (Zhang and Talalay 1994). Protection had been reported to be afforded by α-naphthyl-, β-naphthyl-, phenyl-, benzyl-, phenethyl- and other arylalkyl isothiocyanates against tumour development in liver, lung, mammary gland, forestomach and esophagus. The anticarcinogenic effects of isothiocyanates appeared to be mediated by tandem and cooperating mechanisms: (a) suppression of carcinogen activation by cytochrome P450, probably by a combination of downregulation of enzyme levels and direct inhibition of their catalytic activities, which thereby lower the levels of ultimate carcinogens formed, and (b) induction of phase 2 enzymes such as glutathione transferases and NAD(P)H: quinone reductase, which detoxify

any residual electrophilic metabolites generated by phase I enzymes and thereby destroy their ability to damage DNA. Among isothiocyanates sulforaphane had received a great deal of attention because of its ability to simultaneously modulate multiple cellular targets involved in cancer development, including (i) DNA protection by modulating carcinogen-metabolizing enzymes and blocking the action of mutagens; (ii) inhibition of cell proliferation and induction of apoptosis, thereby retarding or eliminating clonal expansion of initiated, transformed and/or neoplastic cells; and (iii) inhibition of neoangiogenesis, progression of benign tumours to malignant tumours and metastasis formation (Fimognari and Hrelia 2007). Sulforaphane had been reported to prevent, delay or reverse preneoplastic lesions, as well as to act on cancer cells as a therapeutic agent. Isothiocyanates and indoles (e.g., indole-3-carbinol) from *Brassica* vegetables (e.g., broccoli) induce phase I and phase II enzymes responsible for the oxidation, reduction and metabolism of endogenous and exogenous carcinogens (Fowke et al. 2006). *Brassica* intake had been associated with reduced risk of colon, lung, bladder, breast, prostate and other cancers.

Numerous epidemiological studies indicated that *Brassica* vegetables in general and broccoli in particular being rich sources of glucosinolates as well as possessing a high content of flavonoids, vitamins and mineral nutrients could protect humans against cancers (Moreno et al. 2006).

In-Vitro Studies

Broccoli contained selenium in the form of methylated selenium compounds (e.g., Se-methylselenocysteine), which can readily be converted into the methylselenol (Keck and Finley 2004). In-vitro studies showed that methylselenol inhibited the migration and invasive potential of HT1080 fibrosarcoma tumour cells (Zeng et al. 2009).

By monitoring quinone reductase induction in cultured murine hepatoma cells as the biological assay, Zhang et al. (1992) isolated and identified (–)-1-isothiocyanato-(4R)-(methylsulphinyl) butane [$\text{CH}_3\text{-SO-(CH}_2\text{)}_4\text{-NCS}$, sulforaphane] as a major and very potent phase II enzyme inducer

in SAGA broccoli. Sulforaphane was found to be a monofunctional inducer, like other anticarcinogenic isothiocyanates and induced phase II enzymes selectively without the induction of aryl hydrocarbon receptor-dependent cytochrome P450 (phase I enzymes). In murine hepatoma cells, sulforaphane was the most potent inducer. Sulforaphane and its sulfide and sulfone analogues induced both quinone reductase and glutathione transferase activities in several mouse tissues. The induction of detoxication enzymes by sulforaphane may be a significant component of the anticarcinogenic action of broccoli. Steam-processed broccoli gave significant cytoprotection in PC-12 (rat adrenal pheochromocytoma) cell line, and the authors asserted that this neuroprotective efficacy warranted further investigation (Roy et al. 2009).

Indole-3-carbinol (I3C) significantly inhibited cell adhesion, spreading and invasion associated with an upregulation of PTEN (a tumour suppressor gene) and E-cadherin (a regulator of cell–cell adhesion) expression in T47-D human breast cancer cells (Meng et al. 2000). Thus, I3C exhibited anticancer activities by suppressing breast tumour cell growth and metastatic spread. Studies demonstrated that extracts of broccoli and water cress suppressed TPA(12-*O*-tetradecanoylphorbol-13-acetate)-induced matrix metalloproteinase-9 activity and invasiveness of human MDA-MB-231 breast cancer cells in a concentration-dependent manner (Rose et al. 2005). The inhibitory effects of each vegetable were associated with the presence of 4-methylsulfinylbutyl (sulforaphane) and 7-methylsulphinylheptyl isothiocyanates. Sulforaphane and 2-oxohexyl isothiocyanate were found to be potent inducers of detoxication phase 2 enzymes in mouse tissues and murine hepatoma cells in culture (Misiewicz et al. 2003). Sulforaphane was shown to induce cell growth arrest of murine leukemia L-1210 and human melanoma ME-18 cells in a dose-dependent manner, followed by cell death via an apoptotic process. The mammary MCF-7 cancer suppressive action of sulforaphane was found to involve mitotic cell cycle arrest and disruption of normal tubulin polymerization (Jackson and Singletary 2004).

Moon et al. (2009) found that sulforaphane suppressed that tumour necrosis factor- α (TNF- α)-induced NF- κ B activity and induced apoptosis through activation of reactive oxygen species S-dependent caspase-3 in TNF- α -resistant leukemia cells (THP-1, HL60, U937 and K562). Studies showed that the anti-proliferative effects of benzyl and phenethyl isothiocyanates (PEITC) towards Caco-2 cells were due at least in part to the activation of the G₂/M DNA damage checkpoint and that sustained G₂/M phase cell cycle arrest in response to benzyl and phenethyl isothiocyanates may be maintained through upregulation of p21 (Visanji et al. 2004). The crude extract (80 % alcohol extract) of broccoli florets showed good inhibition of colon cancer (IC₅₀ 3.88 μ g/ml) (Hashem et al. 2012b). In contrast each of the successive extracts (petroleum ether, chloroform, ethyl acetate and ethanol) showed no significant cytotoxic activity. When myrosinase hydrolysate was tested for cytotoxic activity on the colon cancer cell line, it showed very high activity—95 % lethality up to 0.78 μ g/ml.

Zhang et al. (2003) reported that indole-3-carbinol (I3C) suppressed the growth of LNCaP prostate carcinoma cells in a dose-dependent manner by inducing a G1 block in cell cycle progression. I3C selectively inhibited the expression of CDK6 protein and transcripts and strongly stimulated the production of the p16 CDK inhibitor. In LNCaP prostate carcinoma cells, I3C treatment inhibited production of PSA, whereas combinations of I3C and the androgen antagonist flutamide more effectively inhibited DNA synthesis and PSA levels compared with either agent alone.

Animal Studies

Dietary supplementation of calcium-D-glucarate, the calcium salt of glucaric acid, contained in broccoli, had been shown to inhibit β -glucuronidase, an enzyme produced by colonic bacterial flora and involved in phase II liver detoxification (Dwivedi et al. 1990). A 4 % calcium glucarate-supplemented diet inhibited β -glucuronidase activity by 70 and 54 % of the bacterial flora obtained from proximal (small intestine) and

distal (colon) segments of intestine, respectively. Elevated β -glucuronidase activity had been found to be associated with an increased risk for various cancers, particularly hormone-dependent cancers such as breast, prostate and colon cancers. One of glucaric acid derivatives, the potent β -glucuronidase inhibitor D-glucaro-1,4-lactone (1,4-GL), had been found to increase detoxification of carcinogens and tumour promoters/progessors by inhibiting β -glucuronidase and preventing hydrolysis of their glucuronides (Walaszek et al. 1997). 1,4-GL and its precursors, such as potassium hydrogen D-glucarate and calcium D-glucarate, may exert their anticancer action, in part, through alterations in steroidogenesis accompanied by changes in the hormonal environment and the proliferative status of the target organ. Thus, GA and its derivatives may be useful as new or adjuvant cancer preventive and therapeutic agents. Other potential clinical applications of oral calcium-D-glucarate include regulation of estrogen metabolism and as a lipid-lowering agent (Anonymous 2002).

Talalay et al. (1995) reported that phase 2 enzymes (e.g., glutathione transferase, NAD(P)H-quinone reductase, UDP-glucuronosyltransferases) and high intracellular levels of glutathione in mammalian cells played a prominent role in providing protection against the toxic and neoplastic effects of electrophilic metabolites of carcinogens and reactive oxygen species. Phase 2 enzymes are transcriptionally induced by low concentrations of a wide variety of chemical agents such as phenolic antioxidants, Michael reaction acceptors, isothiocyanates, 1,2-dithiole-3-thiones, trivalent arsenicals, HgCl₂ and organomercurials, hydroperoxides and vicinal dimercaptans. Such induction suppressed chemical carcinogenesis via the antioxidant/electrophile response element (ARE/EpRE). Search for such inducer activity in broccoli afforded the isolation of sulforaphane, an isothiocyanate, as a very potent phase 2 enzyme inducer that suppressed mammary tumour formation in rats (Talalay et al. 1995). Studies confirmed that sulforaphane and three synthetic norbornyl isothiocyanates acted as norbornyl isothiocyanates in blocking the formation of mammary tumours in Sprague–Dawley

rats treated with single doses of 9,10-dimethyl-1,2-benzanthracene (Zhang et al. 1994).

Studies found that extracts of 3-day-old broccoli sprouts (containing either glucoraphanin or sulforaphane as the principal enzyme inducer) were highly effective in reducing the incidence, multiplicity and rate of development of mammary tumours in dimethylbenz(a)anthracene-treated rats (Fahey et al. 1997). Hence, small quantities of crucifer sprouts may protect against the risk of cancer as effectively as much larger quantities of mature vegetables of the same variety.

Studies in male F344 rats showed that phenethyl isothiocyanate (PEITC), a broccoli component, selectively inhibited lung metabolic activation of carcinogens, 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone (NNK) and 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanol (NNAL), a major metabolite of NNK (Staretz et al. 1997). The results supported the hypothesis that PEITC inhibited NNK-induced lung tumours by inhibiting metabolic activation of NNK in the lung. This study also demonstrated that PEITC inhibited lung alpha-hydroxylation of NNAL; this may play a role in PEITC inhibition of lung tumorigenesis by NNK. Boysen et al. (2003) demonstrated that dietary 2-phenethyl isothiocyanate (PEITC), or a dietary mixture of benzyl isothiocyanate (BITC) plus PEITC, inhibited the formation of 4-hydroxy-1-(3-pyridyl)-1-butanone (HPB) releasing adducts of benzo[a]pyrene (B[a]P) and 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone (NNK) in the lung of A/J mice, leading to inhibition of lung tumorigenesis induced by NNK. Oral administration of sulforaphane (SFN) to benzo(a)pyrene [B(a)P]-induced lung cancer in Swiss albino mice mitigated the damaging effects of B(a)P in mice by upholding the GSH redox cycle and stabilizing the thiol status (Kalpana et al. 2011). SFN was also found to prevent formation of leaky membranes by boosting the antioxidant status, leading to maintenance of ATPase activity in B(a)P-treated animal and reduced carcinogen-associated morphological changes in the lung tissue. Further, they found that sulforaphane treatment decreased hydrogen peroxide production in benzo(a)pyrene [B(a)P]-induced lung cancer in Swiss albino mice, confirming its

antioxidant potential (Kalpana et al. 2013). Apoptosis was induced by increasing the release of cytochrome c from mitochondria, decreasing expression of Bcl-2 and increasing expression of Bax. Caspase-3 activity was also enhanced leading to DNA fragmentation in SFN-treated groups.

Sulforaphane blocked benzo[a]pyrene-evoked forestomach tumours in ICR mice (Fahey et al. 2002). This protection resulted from induction of phase 2 detoxication and antioxidant enzymes and was abrogated in mice lacking the *nrf2* gene, which regulated phase 2 enzymes. Studies demonstrated that *ApcMin/+* mice fed with sulforaphane-supplemented diet developed significantly less and smaller polyps with higher apoptotic and lower proliferative indices in their small intestine in a dose-dependent manner (Hu et al. 2006). Immunohistochemical staining of the adenomas indicated that sulforaphane significantly suppressed the expression of phosphorylated c-Jun N-terminal kinase (p-JNK), phosphorylated extracellular signal-regulated kinases (p-ERK) and phosphorylated-Akt (p-Akt), which were found to be highly expressed in the adenomas of *ApcMin/+* mice. It was found that the concentrations between 3 and 30 nmol/g of sulforaphane and its metabolite sulforaphane-GSH were required to prevent, or retard, adenoma formation in the gastrointestinal tract of *ApcMin/+* mice.

Administration of sulforaphane (SFN) and phenethyl isothiocyanate (PEITC), major ITCs in broccoli and watercress, respectively, and their corresponding N:-acetylcysteine (NAC) conjugates showed chemopreventive activity towards azoxymethane (AOM)-induced colonic aberrant crypt foci (ACF) in F344 rats (Chung et al. 2000). SFN, SFN-NAC, PEITC and PEITC-NAC all significantly reduced the formation of total ACF from 153 to 100–116 and multicrypt foci from 52 to 27–38 (more than four crypts/focus) during the post-initiation treatment. However, only SFN and PEITC were effective during the initiation phase, reducing the total ACF from 153 to 109–115 and multicrypt foci from 52 to 35 (more than four crypts/focus). The NAC conjugates were inactive as anti-initiators against AOM-induced ACF. The results indicated a potential role of sulforaphane

and phenethyl isothiocyanate in the protection against colon cancer. Recent studies demonstrated that the chemopreventive effects of sulforaphane on human colon cancer Caco-2 cells may have been partly attributed to Nrf2-mediated UDP-glucuronosyltransferase 1A (UGT1A) induction and apoptosis induction, providing experimental basis for clinical application of sulforaphane to human colon cancer prevention (Wang et al. 2012c).

A broccoli sprout isothiocyanate-rich extract significantly induced both glutathione S-transferase (GST) or NAD(P)H-quinone oxidoreductase 1 (NQO1) in cultured bladder cells in-vitro and in rat bladder tissues in-vivo (Zhang et al. 2006). Deficiency GST or (NQO1) in humans had been reported to be associated with increased risk of urothelial bladder cancer. The study showed broccoli sprout ITC extract to be a potent inducer of GST and NQO1 in the bladder and to be a promising agent for prevention of bladder cancer. Studies showed that combinations of tomato and broccoli enhanced antitumour activity in dunning r3327-h prostate adenocarcinomas in rats (Canene-Adams et al. 2007). Broccoli decreased tumour weights by 42 %, whereas the 10:10 combination with tomato caused a 52 % decrease. Lycopene at 23 or 224 nmol/g of the diet insignificantly reduced tumour weights by 7 or 18 %, respectively, whereas tomato reduced tumour weight by 34 %.

Broccoli and broccoli sprout extracts and pure isothiocyanates were found to inhibit normal, noninvasive (RT4) and invasive (J82, UMUC3 bladder cancer cells) human urothelial cell viability (Abbaoui et al. 2012). Sulforaphane ($IC_{50}=5.66 \mu M$) and erucin ($IC_{50}=8.79 \mu M$) were found to be the most potent inhibitors, and normal cells were least sensitive. This inhibition was associated with downregulation of survivin, epidermal growth factor receptor (EGFR) and human epidermal growth factor receptor 2 (HER2/neu), G₂/M cell cycle accumulation and apoptosis. In a murine UMUC3 xenograft model, feeding semipurified diets containing 4 % broccoli sprouts or 2 % broccoli sprout isothiocyanate extract, or gavaged pure sulforaphane or erucin (each at 295 $\mu mol/kg$, similar to dietary exposure) elicited report tumour weight reduction of

42, 42, 33, and 58 %, respectively. Sulforaphane and erucin metabolites were present in mouse plasma (micromolar range) and tumour tissue, with *N*-acetylcysteine conjugates as the most abundant. Interconversion of sulforaphane and erucin metabolites was observed.

Clinical Studies

In both men and women, oral ingestion of dietary indole-3-carbinol (I3C), which is present in cruciferous vegetables (e.g., cabbage, cauliflower and broccoli), significantly increased the urinary excretion of C-2 estrogens (Michnovicz et al. 1997). The urinary concentrations of nearly all other estrogen metabolites, including levels of estradiol, estrone, estriol and 16 α -hydroxyestrone, were lower after I3C treatment. The results confirmed the hypothesis that I3C induced estrogen 2-hydroxylation, resulting in decreased concentrations of several metabolites known to activate the estrogen receptor. This effect may have a beneficial effect on estrogen metabolism and may lower estrogenic stimulation in women. I3C may have chemopreventive activity against breast cancer in humans.

Hecht et al. (2004) investigated the effects of cruciferous vegetable (including cauliflower, broccoli) consumption on the metabolism of the tobacco-specific lung carcinogen 4-(methyl-nitrosamino)-1-(3-pyridyl)-1-butanone (NNK) in 84 smokers. They found that glucobrassicins, which release indole-3-carbinols on chewing, were the major glucosinolates in seven of the nine cruciferous vegetables, accounting for 70.0–93.2 % of all glucosinolates in these vegetables. There was a significant correlation ($P=0.01$) between increased consumption of glucobrassicins and decreased levels of metabolites of NNK: 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanol (NNAL) and its glucuronides (NNAL-Glucs) in urine after adjustment for number of cigarettes smoked per day. Their results were consistent with those of previous studies, which demonstrated that indole-3-carbinol decreased levels of urinary NNAL probably by inducing hepatic metabolism of NNK. In a randomized crossover trial ($n=20$) comparing the effects of a *Brassica* vegetable supplementation intervention against a

micronutrient and fibre (M+F) supplementation, *Brassica* intervention was found to significantly decreased urinary F2-isoprostane levels (F2-IP), a stable biomarker of systemic oxidative stress by 21 % compared to baseline and (M+F) intervention (Fowke et al. 2006). Their results suggested that brassica consumption reduces systemic oxidative stress independent of the vitamin and mineral content of these vegetables.

Sulforaphane (SFN), an anticarcinogenic isothiocyanate found in cruciferous vegetables such as broccoli and cauliflower, was first identified as a potent inducer of phase 2 enzyme (Myzak et al. 2007). They found that when consumed in the diet at an average daily dose of 7.5 μ mol per animal for 21 days, SFN suppressed the growth of human PC-3 prostate cancer cells by 40 % in male nude mice. There was a significant decrease in histone deacetylase (HDAC) C activity in the xenografts, as well as in the prostates and mononuclear blood cells (MBC), of mice treated with SFN, compared to controls. There also was a trend towards increased global histone acetylation in the xenografts, prostates and MBC. In human subjects, a single dose of 68 g Broccoli Sprouts inhibited HDAC activity significantly in peripheral blood mononuclear cells (PBMC) 3 and 6 hours following consumption. These findings provided evidence that one mechanism through which SFN acted as a cancer chemopreventive agent in-vivo was through the inhibition of HDAC activity. A study on a group of Jordanians men and women found that dietary consumption of broccoli induced the activities of cytochromes CYP1A2 and CYP2A6 (Hakooz and Hamdan 2007). Induction or inhibition of cytochrome P450 (CYP) enzyme activities, enzymes that activate or detoxify xenobiotics, is one mechanism by which vegetables may alter cancer risk.

In a study of 628 men diagnosed with prostate cancer, conducted at the Fred Hutchinson Cancer Research Center in Seattle, WA, those eating 28 or more servings of vegetables per week showed a 35 % decreased risk for prostate cancer when compared with those eating fewer than 14 servings per week (Cohen et al. 2000). There was also a 41 % decreased risk among men eating three or more servings of cruciferous

vegetables (broccoli, cabbage, Brussels sprouts, cauliflower) per week compared with those eating less than one serving per week, even after controlling for total vegetable intake. In a prospective study of fruit and vegetable intake and risk of prostate cancer, involving 1,338 patients with prostate cancer among 29,361 men (average follow-up=4.2 years) in the screening arm of the Prostate, Lung, Colorectal and Ovarian Cancer Screening Trial, Kirsh et al. (2007) found that a high intake of cruciferous vegetables, including broccoli and cauliflower, may be associated with reduced risk of aggressive prostate cancer, particularly extraprostatic disease.

The results of 7 cohort studies and 87 case-control studies on the association between brassica consumption and cancer risk showed inverse associations between the consumption of cabbage, cauliflower and broccoli and risk of lung cancer; between the consumption of brassicas and risk of stomach cancer; between broccoli consumption and risk of all cancers taken together; and between brassica consumption and the occurrence of second primary cancers (Verhoeven et al. 1996). Of the case-control studies, 67 % showed an inverse association between consumption of total brassica vegetables and risk of cancer at various sites. For cabbage, broccoli, cauliflower and Brussels sprouts, these percentages were 70, 56, 67 and 29 %, respectively. Although the measured effects might have been distorted by various types of bias, it was concluded that a high consumption of brassica vegetables was associated with a decreased risk of cancer.

Antimutagenic/Anticlastogenic Activities

Studies found that glucosinolate-rich broccoli seed extracts inhibited mutagenesis induced by the S9-dependent mutagen (2-aminofluorene) more significantly than direct-acting mutagens (Rampal et al. 2010). Out of the four extracts tested, 0.1 mol/l of HCl extract was found to be the most effective in inhibiting mutagenesis with both TA 98 and TA 100 strains of *Salmonella*

typhimurium. All other extracts also showed pronounced antimutagenic potential. The results of this study indicated the presence of potent antigenotoxic factors in broccoli. In the Ames mutagenic test using *Salmonella typhimurium* TA 100, high pressure or freezing treatment of broccoli juice exerted strongly positive test MNU (2-nitroso-2-methylurea) mutagen inhibition (Totušek et al. 2011). In the Ames mutagenic test using *Salmonella typhimurium* TA 98, high pressure or freezing treatment of broccoli juice exerted strongly positive test on IQ (2-amino-3-methyl-3H-imidazo-[4,5-f]quinoline) mutagen inhibition. In the clastogenicity test assessed using the micronucleus test animals administered broccoli juice and MNU or broccoli and IQ, a statistically significant reduction in micronuclei number was found compared to MNU- or IQ-treated animals, both with high micronuclei numbers. The results indicated the suppressive action of broccoli juice on clastogenic effects of MNU.

Antiviral Activity

Sulforaphane was found to inhibit Epstein–Barr virus (EBV) reactivation in nasopharyngeal carcinoma cells, thereby decreasing virus production (Wu et al. 2012). It was found that sulforaphane inhibited transactivation activity of the EBV immediate-early gene Rta but not Zta and had the capability to inhibit EBV lytic cycle.

Antimicrobial Activity

It was found that 23 out of 28 different microbial species were inhibited in-vitro by sulforaphane (found abundantly in broccoli) with a minimal inhibitory concentration (MIC) ranging from 1 to 4 µg/ml (Johansson et al. 2008). Five pathogens—*Pseudomonas aeruginosa*, three methicillin-resistant *Staphylococcus aureus* (MRSA) isolates and *Candida albicans*—were considered resistant to sulforaphane having MICs ≥ 16–32 µg/ml.

Two novel glucosinolates identified as 2-mercaptomethyl sulfinyl glucosinolate (1) and

(Z)-1-((2S,5S)-5-hydroxytetra-hydro-2H-pyran-2-ylthio)-2-(1H-indol-3-yl) ethylidene amino sulfate (2) and a known cinnamoyl [6'-O-trans-(4''-hydroxy cinnamoyl)4-(methylsulphonyl)butyl glucosinolate] (3) isolated from broccoli florets exhibited antimicrobial activity (Survay et al. 2012). Both compounds 1 and 3 showed a significant and similar antimicrobial activity against *Staphylococcus aureus* with an IC₅₀ of <625 µg/ml when compared to antibiotic Duricef. Against *Salmonella typhimurium*, the IC₅₀ of 1 and 3 was determined as <625 and <1,250 µg/ml, respectively, when compared to ampicillin (IC₅₀ ≤ 39 µg/mL) as a positive control. Ethyl acetate and chloroform extracts of broccoli were found to be effective against Gram-positive bacteria *Bacillus cereus* and *Bacillus subtilis* and *Candida albicans* (Hashem et al. 2012a). The ethyl acetate and ethanol extracts were highly active against *E. coli* (Gram negative). Sulforaphane and erucin, two natural isothiocyanates highly abundant in broccoli, were found to strongly inhibit quorum sensing and virulence in *Pseudomonas aeruginosa* (Ganin et al. 2013). Mechanistic evaluations of these effects suggested that these isothiocyanates were antagonists of the transcriptional activator LasR.

Gastroprotective Activity

Studies found that sulforaphane, a component in broccoli and broccoli sprouts, exhibited potent bacteriostatic activity against 3 reference strains and 45 clinical isolates of *Helicobacter pylori* with MIC₉₀ value of <4 g/ml (Fahey et al. 2002). *H. pylori* was completely eradicated in 8 of the 11 sulforaphane-treated human gastric xenografts implanted in nude mice, suggesting that sulforaphane might be beneficial in the treatment of *H. pylori*-infected individuals (Haristoy et al. 2003). Twelve isothiocyanates (ITC) including sulforaphane exerted antibacterial activity against 25 strains of *H. pylori* in-vitro (Haristoy et al. 2005). The MIC₉₀ values for these ITCs ranged between 4 and 32 µg/ml, and 4 of the most potent compounds exhibited bactericidal activity against both extra- and intracellular bacteria.

Nine *Helicobacter pylori*-positive patients completed the oral treatment with broccoli sprouts (14, 28 or 56 g) twice daily for 7 days (Galan et al. 2004). Seven of nine (78 %) patients were stool antigen negative immediately after the completion of therapy, and 6 remained negative at day 35. Urea breath testing was completed on six patients. Two patients were negative, two positive and two indeterminate. Six patients rated the taste of broccoli sprouts from okay to very good; one patient stated they were “not good.” Consumption of oral broccoli sprouts was temporally associated with eradication of *H. pylori* infection in three of nine patients. Most patients found broccoli sprouts palatable.

Dietary treatment of C57BL/6 female mice infected with *H. pylori* Sydney strain 1 with sulforaphane-rich broccoli sprouts reduced gastric bacterial colonization, attenuated mucosal expression of tumour necrosis factor- α and interleukin-1 β , mitigated corpus inflammation and prevented expression of high salt-induced gastric corpus atrophy (Yanaka et al. 2009). This therapeutic effect was not observed in mice in which the *nrf2* gene was deleted, strongly implicating the important role of Nrf2-dependent antioxidant and antiinflammatory proteins in sulforaphane F-dependent protection. In a randomized, placebo-controlled study of 48 patients, 8-week dietary intervention with broccoli sprouts, but not with placebo, decreased the levels of urease and *H. pylori* stool antigen (both biomarkers of *H. pylori* colonization) and serum pepsinogens I and II (biomarkers of gastric inflammation). Daily intake of sulforaphane-rich broccoli sprouts for 2 months reduced *H. pylori* colonization in mice and improved the sequelae of infection in infected mice and in humans. This treatment appeared to enhance chemoprotection of the gastric mucosa against *H. pylori*-induced oxidative stress.

Cardiovascular Protective (Antihypertensive/Antihypercholesterolemic) Activities

An in-vivo study in rats showed that dietary intake of broccoli sprouts containing glucoraphanin, which metabolized into the phase 2 protein inducer

sulforaphane, resulted in significantly decreased oxidative stress in cardiovascular and kidney tissues, as shown by increased glutathione (GSH) content and decreased oxidized GSH, decreased protein nitrosylation, as well as increased GSH reductase and GSH peroxidase activities (Wu et al. 2004). Decreased oxidative stress correlated with better endothelial-dependent relaxation of the aorta and significantly lowered (20 mmHg) blood pressure. Thus, consuming broccoli containing phase 2 protein inducers reduces the risk of developing cardiovascular problems of hypertension and atherosclerosis.

Studies showed that consumption of broccoli sprouts containing 20 μ mol of glucoraphanin (BS10X) had more marked effects on cholesterol homeostasis than glucoraphanin-rich broccoli sprout (GRE) and sulforaphane-rich broccoli sprout (SFE) extracts in Syrian hamsters with dietary-induced hypercholesterolemia (Rodríguez-Cantú et al. 2011). Hepatic cholesterol was reduced by BS10X and SFE treatments in all animals. This correlated with a downregulation of gene expression of sterol regulatory element-binding proteins (SREBP-1 and SREBP-2) and fatty acid synthase caused by GRE and SFE diets. BS10X caused changes in gene expression in a gender-specific manner; additionally, it increased coprostanol excretion in females.

In a phase 1 study of 12 subjects, it was found that consuming broccoli sprouts 100 g daily for a week showed a reduction in total cholesterol, LDL cholesterol and an increase in HDL cholesterol (Murashima et al. 2004). All subjects showed decreased plasma cysteine, plasma PCOOH (phosphatidylcholine hydroperoxide), urinary 8-isoprostane and urinary 8-OHdG (8-hydroxydeoxyguanosine) and increased serum coenzyme Q(10). There was improved cholesterol metabolism and decrease in oxidative stress markers.

Photoprotective Activity

The UV radiation-induced skin carcinogenesis in “initiated high-risk mice” was substantially inhibited by broccoli sprout extracts containing sulforaphane (Dinkova-Kostova et al. 2006).

After completion of the UV irradiation schedule (30 mJ/cm²/session twice a week for 20 weeks), mice treated topically with broccoli sprout extract containing 1.0 µmol (high-dose) sulforaphane for 5 days a week for 11 weeks had their tumour burden, incidence and multiplicity reduced by 50 % compared to 100 % tumour incidence in untreated control mice. Sulforaphane inhibited cytokine-dependent (gamma-interferon or lipopolysaccharide) induction of iNOS in RAW 264.7 macrophages. The results showed topical application of sulforaphane-containing broccoli sprout extracts to be a promising strategy. Treatment of murine and human keratinocytes with the isothiocyanate sulforaphane elevated phase 2 enzymes and glutathione and protected against oxidant toxicity. Topical application of sulforaphane-containing broccoli sprouts extracts induced the phase 2 response in mouse skin *in vivo*. Topical application of broccoli sprout extract delivering 100 nmol sulforaphane/cm(2) increased the protein levels of NAD(P)H-quinone oxidoreductase 1 (NQO1), glutathione S-transferase A1 and heme oxygenase 1, three representative phase 2 enzymes, in mouse skin epidermis (Dinkova-Kostova et al. 2007). Quantitative assessment of the activity of NQO1 24 hours after dosing showed increases of 1.5- and 2.7-fold after application of single and multiple (thrice, every 24 hours) doses, respectively. A dose-escalation safety study in healthy human subjects revealed no adverse reactions when doses as high as 340 nmol of sulforaphane in the form of broccoli sprout extracts were applied topically to the center of a 1 cm diameter circle drawn on the volar forearm. The enzyme activity of NQO1 in homogenates of 3 mm full thickness skin punch biopsies increased in a dose-dependent manner, with maximum increases of 1.5- and 4.5-fold after application of 150 nmol doses, once or three times (at 24-hours intervals), respectively, thus providing direct evidence for induction of the phase 2 response in humans. Further they found that feeding broccoli sprout extracts (providing daily doses of 10 µmol of glucoraphanin) to SKH-1 hairless mice with prior chronic exposure to UV radiation (30 mJ/cm²) of UVB, twice a week, for 17 weeks) inhibited the development

of skin tumours during the subsequent 13 weeks (Dinkova-Kostova et al. 2010). Compared to the controls, tumour incidence, multiplicity and volume were reduced by 25, 47 and 70 %, respectively, in the animals that received the protective agent.

Studies showed that topical application of sulforaphane-rich extracts of 3-day-old broccoli sprouts stimulated phase 2 enzymes in the mouse and human skin, protected against UV radiation-induced inflammation and edema in mice, and reduced susceptibility to erythema arising from narrowband 311-nm UVR in humans (Talalay et al. 2007). Mean erythema reduction in six human subjects was 37.7 %, and protection was catalytic and long-lasting.

Anticataract Activity

After treatment of human adult retinal pigment epithelial cells for 24 hours with 0–5 µM concentrations of sulforaphane (a potent phase 2 enzyme inducer isolated from broccoli), the toxicities of the oxidants (menadione, tert-butyl hydroperoxide, 4-hydroxynonenal and peroxynitrite) were markedly reduced as shown by 1.5- to 3-fold increases in D(m) values (Gao et al. 2001). Protection was prolonged and persisted for several days after removal of sulforaphane before returning to control levels. The sulforaphane-dependent increases in specific activities of cytosolic quinone reductase and the glutathione levels were highly significantly correlated with the degree of protection as measured by D(m) values. Antioxidant protection was also demonstrated for human HaCaT keratinocytes and L1210 murine leukemia cells. Significant protection of retinal pigment epithelial cells against UV light (320–400 nm) photooxidative cytotoxicity was obtained by prior treatment with phase 2 gene inducers, such as the isothiocyanate sulforaphane or a bis-2-hydroxybenzylideneacetone Michael reaction acceptor (Gao and Talalay 2004). The degree of protection was correlated with the potencies of these inducers in elevating cytoprotective glutathione levels and activities of NAD(P)H-quinone oxidoreductase.

The flavonoid fraction of broccoli was found to prevent selenite-induced cataractogenesis in Sprague–Dawley albino rat pups, possibly by maintaining antioxidant status and ionic balance through Ca^{2+} ATPase pump, inhibition of lipid peroxidation, calpain activation and protein insolubilization (Vibin et al. 2010).

In a prospective cohort study of 36,644 men (45–75 years), it was found that men who consumed specific foods high in carotenoids, lutein and zeaxanthin, like broccoli and spinach, twice a week, had a modestly lower risk of cataract (Brown et al. 1999).

Immunomodulatory Activity

Administration of allyl isothiocyanate (AITC) and phenyl isothiocyanate (PITC) was found to stimulate the immunological response in Balb/c mice (Manesh and Kuttan 2003). Both isothiocyanates augmented total WBC count and alpha-esterase positive cell number. Treatment with AITC and PITC along with the antigen sheep red blood cells (SRBC) produced an enhancement in the circulating antibody titer and the number of plaque-forming cells in the spleen. Similarly intraperitoneal administration of sulforaphane to Balb/c mice enhanced total WBC count and alpha-esterase positive cell number (Thejass and Kuttan 2007a). Treatment with sulforaphane along with the antigen, sheep red blood cells (SRBC), produced an enhancement in the circulating antibody titre and the number of plaque-forming cells in the spleen and in the phagocytic activity of peritoneal macrophages. Also sulforaphane significantly reduced the elevated level of TNF-alpha production by LPS-stimulated macrophages. They also found that administration of sulforaphane significantly enhanced natural killer cell activity and antibody-dependent cellular cytotoxicity in B16F-10 melanoma-induced metastasis-bearing C57BL/6 mice (Thejass and Kuttan 2007b). Administration of sulforaphane significantly enhanced the production of IL-2 and IFN-gamma in metastatic tumour-bearing animals and sulforaphane significantly down-regulated the serum levels of proinflammatory

cytokines such as IL-1beta, IL-6, TNF-alpha and GM-CSF during metastasis. The results suggested that sulforaphane effectively inhibited the spread of metastatic tumour cells through the stimulation of cell-mediated immune response, upregulation of IL-2 and IFN-gamma and downregulation of proinflammatory cytokines IL-1beta, IL-6, TNF-alpha and GM-CSF.

Antiinflammatory Activity

Heiss et al. (2001) found a potent decrease in lipopolysaccharide (LPS)-induced secretion of proinflammatory and pro-carcinogenic signaling factors (NO, prostaglandin E(2) and tumour necrosis factor alpha) in cultured Raw 264.7 macrophages after sulforaphane treatment. Sulforaphane selectively reduced DNA binding of NF-kappa B, a pivotal transcription factor in LPS-stimulated proinflammatory response, without interfering with LPS-induced degradation of the inhibitor of NF-kappa B nor with nuclear translocation of NF-kappaB. Their data indicated that antiinflammatory mechanisms contribute to sulforaphane-mediated cancer chemoprevention.

In animal studies, dietary intake of dried broccoli sprouts containing high amounts of glucoraphanin that afforded phase 2 protein-inducing isothiocyanate sulforaphane was found to decrease aging-associated degenerative and inflammatory changes in spontaneously hypertensive rat stroke-prone rat central nervous system (Noyan-Ashraf et al. 2005). Recent animal studies showed that treatment of rats under noninflamed conditions with broccoli extract and the essential oils of turmeric, thyme and rosemary promoted intestinal health by reducing the proinflammatory adhesion molecule VCAM-1 and by increasing the tight junction marker Cldn3, leading to an improved gut barrier (Mueller et al. 2013). These phytogetic additives also exhibited antiinflammatory properties as indicated by the reduction of the dextran sulphate sodium-induced increase in proinflammatory mediators like NFkB, VCAM-1, MCP-1 and COX2 to varying degree in rats.

Weight Loss Activity

The chloroform extract, the combined ethyl acetate and ethanol extracts and the crude extract of broccoli florets at 5 and 1 % of diet elicited significant body weight loss in female rats, 180, 85 and 75 g total loss in body weight, respectively (Motawea et al. 2010). When these results were compared with the water extract of green tea (117 g loss), the chloroform broccoli extract was more active. No toxicity was observed in the crude broccoli extract up to 10 g/kg body weight in rats in the LD₅₀ test.

Pharmacokinetic Studies

The gastric digestion (in-vitro) of broccoli caused high losses in glucosinolates (69 % loss), whereas phenolics and vitamin C presented higher stability under these conditions (Vallejo et al. 2004a). There were no losses in flavonoids, a 7 % loss of vitamin C and a variable rate of loss (6–25 %) in hydroxycinnamic acid derivatives were observed. Under in-vitro intestinal conditions, flavonoids and hydroxycinnamoyl acid derivatives were of low availability, due to their significant losses (84 and 80 % loss, respectively) under these conditions, at the end of the experiment. Vitamin C showed greater decrease after intestinal digestion (91 % loss). Regarding the remaining glucosinolates, these compounds presented higher stability under intestinal conditions, rendering an availability similar to that found for phenolics (75 % loss). The study showed glucosinolates were mainly degraded by gastric conditions, whereas phenolic compounds and vitamin C were degraded by intestinal conditions.

In a crossover study of healthy volunteers, urinary dithiocarbamate excretion increased sharply after administration of broccoli sprout glucosinolates or isothiocyanates (Shapiro et al. 2001). Cumulative excretion of dithiocarbamates following 111- μ mol doses of isothiocyanates was greater than that after glucosinolates. In subjects fed four repeated 50 μ mol doses of isothiocyanates, the intra- and intersubject variation in dithiocarbamate excretion was very small, and

after escalating doses, excretion was linear over a 25–200 μ mol dose range. Dithiocarbamate excretion was higher when intact sprouts were chewed thoroughly rather than swallowed whole. The studies indicated that isothiocyanates were about six times more bioavailable than glucosinolates, which must first be hydrolyzed. Thorough chewing of fresh sprouts exposed the glucosinolates to plant myrosinase and significantly increased dithiocarbamate excretion. In another crossover study of 12 subjects, the bioavailability of sulforaphane and erucin (two important isothiocyanates from broccoli) was dramatically lower when subjects consumed broccoli supplements compared to fresh broccoli sprouts (Clarke et al. 2011). The peaks in plasma concentrations and urinary excretion were also delayed when subjects consumed the broccoli supplement. Interconversion of sulforaphane and erucin metabolites was observed. The study confirmed that consumption of broccoli supplements devoid of myrosinase activity did not produce equivalent plasma concentrations of the bioactive isothiocyanate metabolites compared to broccoli sprouts.

Food Safety Studies

Putrescine, cadaverine, histamine, tyramine, spermidine and spermine increased during broccoli and radish sprout production although these levels were below those permitted by legislation (5 mg/100 g of edible food) (Martínez-Villaluenga et al. 2008). Broccoli and radish sprouts demonstrated no toxic effects on proliferation and viability of human promyelocytic leukemia cells and should be included in diets as healthy and safe fresh foods. Owing to the effect of broccoli constituents on the cytochrome P450 system, involved in the metabolism of various medicines, interactions could occur with these medicines (Fahey et al. 2001). Isothiocyanates had been reported to have a goitrogenic effects, but Fahey et al. (2001) asserted that there was no reason to assume that consumption of (isothiocyanates from) *Brassica* varieties should have a negative effect on the thyroid in people who do not have

a thyroid condition, particularly where iodine intake was adequate.

Allergy Problems

Work-related symptoms such as rhinitis, conjunctivitis, asthma and urticaria caused by broccoli and cauliflower pollen were reported by 44 % of the participants (24/54), of whom all but one had positive skin-prick tests for cauliflower- and/or broccoli-pollen/flower extracts, and 58 % (14/24) had positive radioallergosorbent test (RAST) results (Hermanides et al. 2006). Symptoms had developed within the first 2 years in 33 % of the patients. Six patients had to stop or change work.

Traditional Medicinal Uses

One unusual phytotherapeutic role of broccoli is for skin diseases—the juice of the leaves is used to treat warts (Moreno et al. 2006).

Other Uses

Broccoli by-products (harvest remains) resulting from greenhouse cultivation still contained bioactive compounds (glucosinolates, phenolic acids and flavonoids), and nutrients (vitamin C, minerals and trace elements), with radical-scavenging capacity, and may be useful as sources of nutrients and potentially functional ingredients, giving the opportunity to obtain added-value products and reduce agrowaste costs and environmental problems (Domínguez-Perles et al. 2010).

Comments

Cauliflower and broccoli have been classified in convar. *botrytis* (L.) Alef. as *Brassica oleracea* var. *botrytis* L. and var. *italica* Plenck, respectively (Tjeertes 2004). They can best be considered as cultivar groups and as such have been called *B. oleracea* (Cauliflower Group) and (Broccoli

Group) (Van der Vossen 1994; Tjeertes 2004) or *B. oleracea* (Botrytis Group) or *B. oleracea* (Italica Group) (Porcher et al. 1995–2020). However, most scientific papers use the name *B. oleracea* var. *botrytis* and *B. oleracea* var. *italica* for cauliflower and broccoli, respectively.

Brassica oleracea italica
x alboglabra

Scientific Name

Brassica oleracea italica x alboglabra

Synonyms

Brassica oleracea (Italica x Alboglabra Group)

Family

Brassicaceae

Common/English Names

Asparation, Asparations, Baby Broccoli, Bimi, Broccollette, Broccoletti, Broccolini, Sweet Baby Broccoli, Tenderstem, Tenderstem Broccoli

Vernacular Name

Brazil: broccolis

Origin/Distribution

The hybrid cultivar was developed by the Sakata Seed Company of Yokohama, Japan, in 1993 and named 'aspabroc'. In 1994, Sakata Seed Company in partnership with Sanbon Incorporated began growing 'aspabroc' commercially in Mexico under the name Asparation®. Asparation® first appeared in US markets in 1996. In 1998, Mann Packing Company in collaboration with Sakata Seed Company began marketing 'Aspabroc' throughout the United States under the name Broccolini.

Agroecology

Broccolini is a cool climate crop, sharing the same agroecological requirements as broccoli. It is intolerant of temperature extremes and is more sensitive to cold temperatures than broccoli and is more tolerant of slightly higher temperatures than broccoli.

Edible Plant Parts and Uses

The entire vegetable (leaves, tender young stems, unopened flowering shoots and flowers) is consumable. Broccolini is usually sold as the young tender unopened flowering shoot of 15–20 cm length; some supermarket chains allow a maximum of four opened flowers in the unopened flowering shoot product. Broccolini's flavour is sweet, with notes of both broccoli and asparagus. Broccolini can be sauteed, steamed, boiled, roasted, grilled and stir-fried. Broccolini makes a great appetizer, pasta or risotto ingredient and pizza topping. Broccolini's flavour goes well with butter, olive oil, light-bodied vinegars, lemon, lime, garlic, tomatoes, chillies, cured meats such as pancetta and prosciutto, barbecued

meat, flaky white fish, hard cheeses (parmesan and pecorino) or fresh cheeses (chevre and feta).

Botany

The plant has a structure similar to the sprouting type of broccoli. It is erect, annual or biennial, herbaceous and glabrous up to 80 cm high with an elongated slender, green stem, 15–30 cm long, branching at the top with relatively small, loosely arranged racemose heads. Leaves alternate, petiolate, simple, ovate to ovate-oblong, 40–50×30–40 cm, pinnatipartite or lobed with undulating, shallowly dentate margin, grey-green or blue green. The racemose flower heads are fully exposed from an early stage on slender rachis and peduncles unlike the heading or calabrese broccoli with larger compact head and thick peduncle and rachis. Flowers tetramerous; bisexual; four green sepals; four yellow, spatulate petals; six stamens, four long and two short; superior, two-loculed ovary. Fruit a slender silique with 10–30 subglobose seeds.

Nutritive/Medicinal Properties

Broccolini was reported to have the following nutrient composition: energy 35 kcal, protein 2.98 g carbohydrate 6.04 g, total dietary fibre 1 g, total sugars 2.04 g, calcium 60 mg, iron 0.68 mg, sodium 25 mg, vitamin C 78 mg and vitamin A 1,500 IU (Anonymous 2012).

The main hydroxycinnamic acids (sinapic, ferulic, *p*-coumaric and caffeic acids) were isolated from broccoli and broccolini by capillary zone electrophoresis (Lee et al. 2011).

Sixteen volatile constituents were identified from the ethanolic extract of broccolini leaves (Wang et al. 2012). The major components were 5-phenyl-undecane (11 %), n-hexadecanoic acid (9.34 %), octadecanoic acid (6.39 %), 1,1,3-trimethyl-3-phenyl-indan (4.0 %), 3-(2-phenylethyl)benzonitrile (3.48 %) and phytol (3.37 %). Three purified fractions (BLF1, BLF2 and BLF3) were obtained from broccolini leaves by extraction of solvents (petroleum ether, ethyl acetate and

n-butanol), and polyamid resin chromatography and the flavonoids content of purified product increased from 10.2 to 41.6 % (Wang and Zhang 2012b). BLF1 was primarily consisted of quercetin (content up to 85.4), BLF2 was primarily composed of kaempferol (content up to 78.5 %), and BLF3 contains two major constituents kaempferol and apigenin (contents up to 82.6 %).

The following isothiocyanates were isolated and identified from broccolini seeds: 3-BITC (3-benzyl-isothiocyanate) (10.8 %), 4-methylpentyl-isothiocyanate (0.5 %), 1-isothiocyanatobutane (26.8 %), PEITC (phenethylisothiocyanate) (22.6 %) and sulforaphane (19.2 %) (Zhang et al. 2011). The glucosinolates contents of broccolini, broccoli and Chinese broccoli seeds were determined to be 39.96, 37.77 and 37.25 $\mu\text{mol/g}$, respectively (Yang and Zhang 2012). Six, eight and four major glucosinolates were identified in broccolini, broccoli and Chinese broccoli seeds, respectively. The common glucosinolates in the three vegetables included 4-methylsulphenylbutyl, 3-butenyl and 4-methylthiobutyl glucosinolates. However, three glucosinolates were different for broccolini and broccoli, one glucosinolate was different for broccolini and Chinese broccoli, and six glucosinolates were different for broccoli and Chinese broccoli.

Anticancer Activity

Studies showed that broccolini leaf flavonoids exhibited a dose-dependent antiproliferative effects in-vitro on four human cancer cell lines (SW480, HepG2, Hela and A549) and induce apoptosis in SW480 cell line (Wang and Zhang 2012a). Studies showed that the crude broccolini Leaf crude extract and the purified flavonoid extracts (BLF1, BLF2 and BLF3) all exhibited an inhibitory effect on the growth of human colon cancer SW480 cell line; the IC_{50} values were estimated to be 88.14, 65.06, 72.62 and 79.42 $\mu\text{g/ml}$, respectively (Wang and Zhang 2012b). The antiproliferative activities on SW480 cells were increased by 10–26 % after purification. Broccolini seed extract exhibited antiproliferative effects on

human lung A549 and ovarian OVCAR-3 cancer cells in a dose-dependent manner by using MTT assay, giving IC_{50} values of 81.49 and 78.6 $\mu\text{g/ml}$, respectively (Yang and Zhang 2011). Further, at high dosage (90–120 $\mu\text{g/ml}$), the morphology structure of OVCAR-3 cells became irregular and exhibited characteristics of apoptosis such as cell membrane shrinkage, condensation and fragmentation of nuclear chromatin, as well as formation of apoptotic bodies. Isothiocyanates from broccolini seeds induced apoptosis in human colon cancer SW480 cells in a dose-dependent manner in the MTT assay, and the IC_{50} was calculated to be 77.72 $\mu\text{g/ml}$, superior to the chemotherapeutic drug 5-fluorouracil (Yang et al. 2011).

Other Uses

See notes under broccoli.

Comments

There is a purple broccolini sold under the registered name peacock broccolini. This purple broccolini has small beautifully purple racemose loose flower heads, purple stem and side shoots and large flamboyant purple-tinged edible leaves.

Welsh: Alyswn Pêr, Cuddlin, Cyddlin, Cydlyn

Origin/Distribution

Alyssum is native to southern Europe (France, Portugal, Spain, Italy, Albania and Greece), northern Africa (northern Algeria, Egypt, northern Libya, Morocco and Tunisia), the Azores, the Madeira Islands and the Canary Islands. It has naturalized in other areas in the world, including the United States, Australia, China and Taiwan and some Pacific Islands, e.g. Hawaii and New Caledonia. In Australia, it has widely naturalized in the coastal and subcoastal districts of southeastern

Australia (in eastern New South Wales, southern Victoria, Tasmania, southeastern South Australia and southwest Western Australia) and in south-eastern Queensland, on Norfolk and Lord Howe Islands.

Agroecology

Alyssum does best in areas with a Mediterranean climate where temperatures are mild in winter and warmer in summer and with autumn and spring rainfall and drier periods in summer. It is common on sandy beaches and dunes but can also grow in cultivated fields, stony areas, yards, walls, slopes and waste ground, preferably on calcareous soil, from sea level to 300 m (–2,000 m) altitude. It does well on free-draining sandy and sandy loam soils in full sun but will also grow in partial shade.

Edible Plant Parts and Uses

The young leaves, stems and flowers are used to flavour salads and other dishes where pungency is required (Facciola 1990).

Botany

An erect, ascending or procumbent, pubescent, annual to short-lived perennial herb, 10–30 cm (–40 cm) high with basal branching. Leaves are sessile, simple, linear-lanceolate to lanceolate, 1.5–5 cm long by 0.2–0.4 cm wide, pubescent, green, margin entire, base attenuated and apex acute to subacute (Plates 1, 2, 3 and 4). Inflorescence corymbose-globose, many-flowered and lax when fruiting. Flowers small, fragrant; sepals 1.5–2 mm long, pubescent; petals obovate or suborbicular, 2–3 by 1.5–2.5(–3) mm, clawed, white, pink, apricot, purple to deep purple; stamens short and long with nectar glands at the base and ovate anthers (Plates 1, 2, 3 and 4). Silicula obovate to suborbicular, 2.5–3.5 mm long, sparsely pubescent. Seeds one per locule, ellipsoidal, light to reddish brown, 1–1.5 mm.

Nutritive/Medicinal Properties

Five nucleosides (deoxycytidine, 5-methyldeoxycytidine, deoxyadenosine, deoxyguanosine and thymidine) in the amount of 18.5 % were found in the DNA of *Lobularia maritima* (Wagner and Capesius 1981). The following flavonoids were isolated from the plant: kaempferol, kaempferol 7-rhamnoside, kaempferol 3-glucoside-7-rhamnoside, kaempferol 3-diglucoside and *E*-quercetin 7-glucoside (Matlawska et al. 1989). Sweet alyssum seed had been reported to contain high levels of 6-(methylthio)hexyl- and 6-(methylsulfinyl) hexyl glucosinolates, both of which yielded hydrolysis products of interest, 1-isothiocyanato-6-(methylthio) hexane (lesquerellin) and hesperin (Daxenbichler et al. 1991). Vaughn and Berhow (2005) found alyssum afforded high amounts of glucosinolate hydrolysis products: 3-butenyl isothiocyanate and lesquerellin.

Davis et al. (1998) found that six Brassicacean species including *L. maritima* produced nectar from both lateral nectaries (associated with the short stamens) and median nectaries (outside the long stamens); on average 95 % of the total nectar carbohydrate was collected from the lateral ones. Nectar from these glands possessed a higher glucose/fructose ratio (usually 1.0–1.2) than that from the median nectaries (0.2–0.9) within the same flower. Comparatively little sucrose was detected in any nectar samples. The volatile compound acetophenone was isolated from the flowers (Rohrig et al. 2008).

Four pigments were isolated from *Lobularia maritima* together with a known pigment, as well as three pigments from *Lunaria annua* L. and two known pigments from *Cheiranthus cheiri* (Tatsuzawa et al. 2006). These pigments were determined to be cyanidin 3-*O*-[2-*O*-((acyl-II)-(β -D-xylopyranosyl))-6-*O*-(acyl-I)- β -D-glucopyranoside]-5-*O*-[6-*O*-(acyl-III)- β -D-glucopyranoside], in which the acyl-I group is represented by glucosyl-*p*-coumaric acid, *p*-coumaric acid and ferulic acid; acyl-II by caffeic acid and ferulic acid; and acyl-III by malonic acid, respectively. Four acylated cyanidin 3-sambubioside-5-glucosides were isolated from the purple-violet flowers of *Lobularia maritima* cv. 'Easter Bonnet Violet' along with six known anthocyanins (Tatsuzawa et al. 2007). These new pigments were cyanidin 3-*O*-[2-*O*-(2-*O*-(*trans*-feruloyl)- β -D-xylopyranosyl)-6-*O*-(4-*O*-(β -D-glucopyranosyl)-*trans*-*p*-coumaroyl)- β -D-glucopyranoside]-5-*O*- β -D-glucopyranoside; cyanidin 3-*O*-[2-*O*-(β -D-xylopyranosyl)-6-*O*-(*trans*-feruloyl)- β -D-glucopyranoside]-5-*O*- β -D-glucopyranoside; cyanidin 3-*O*-[2-*O*-(2-*O*-(*trans*-caffeoyl)- β -D-xylopyranosyl)-6-*O*-(*trans*-feruloyl)- β -D-glucopyranoside]-5-*O*- β -D-glucopyranoside or cyanidin 3-*O*-[2-*O*-(2-*O*-(*trans*-feruloyl)- β -D-xylopyranosyl)-6-*O*-(*trans*-caffeoyl)- β -D-glucopyranoside]-5-*O*- β -D-glucopyranoside; and cyanidin 3-*O*-[2-*O*-(2-*O*-(*trans*-feruloyl)- β -D-xylopyranosyl)-6-*O*-(*trans*-feruloyl)- β -D-glucopyranoside]-5-*O*- β -D-glucopyranoside.

Six acylated pelargonidin 3-*O*-sambubioside-5-*O*-glucosides were isolated from red-purple flowers of *Lobularia maritima* cv 'Easter Bonnet Deep Rose' (Tatsuzawa et al. 2010). These pigments were pelargonidin 3-*O*-[2-*O*-(2-*O*-(*trans*-caffeoyl)-xylosyl)-6-*O*-(4-glucosyl-*trans*-*p*-coumaroyl)-glucoside]-5-*O*-glucoside (1); pelargonidin 3-*O*-[2-*O*-(2-*O*-(*trans*-feruloyl)-xylosyl)-6-*O*-(4-glucosyl-*trans*-*p*-coumaroyl)-glucoside]-5-*O*-glucoside (2); pelargonidin 3-*O*-[2-*O*-(2-*O*-(*trans*-caffeoyl)-xylosyl)-6-*O*-(*trans*-coumaroyl)-glucoside]-5-*O*-glucoside (3); pelargonidin 3-*O*-[2-*O*-(caffeoyl)-xylosyl-6-*O*-(feruloyl)-glucoside]-5-*O*-glucoside (4);

pelargonidin 3-*O*-[2-*O*-(2-*O*-(*trans*-feruloyl)-xylosyl)-6-*O*-(*trans*-*p*-coumaroyl)-glucoside]-5-*O*-glucoside (5); and pelargonidin 3-*O*-[2-*O*-(2-*O*-(*trans*-feruloyl)-xylosyl)-6-*O*-(*trans*-feruloyl)-glucoside]-5-*O*-glucoside (6).

Six kaempferol glycosides, four of them characterized for the first time, were isolated from the leaf extract of *Lobularia maritima* (Fiorentino et al. 2009). The four new ones were kaempferol 3-*O*-β-glucopyranosyl-(1 → 2)-*O*-α-xylopyranoside; kaempferol 3-*O*-α-rhamnopyranosyl-(1 → 2)-*O*-α-arabinopyranoside; kaempferol 3-*O*-β-glucopyranosyl-(1 → 2)-*O*-β-glucopyranosyl-7-*O*-α-rhamnopyranoside; and kaempferol 3-*O*-β-glucopyranosyl-(1 → 2)-*O*-β-galactopyranosyl-7-*O*-α-rhamnopyranoside.

Traditional Medicinal Uses

In Spain, Alyssum is commonly used as a diuretic and antiscorbutic (Chopra et al. 1986). It is also highly regarded as an astringent in the treatment of gonorrhoea. In the Amalfi Coast, Campania (Southern Italy), *Lobularia maritima* subsp. *maritima* is used in folk phytotherapy to treat abdominal pains, cold and coughs (Savo et al. 2011).

Other Uses

Alyssum is primarily grown as an ornamental in pots, hanging baskets, mass planting in border fronts or rock gardens. Alyssum also provides a wonderful ground cover.

A hymenopteran parasitoid attractant, acetophenone, was isolated from *L. maritima* flowers (Rohrig et al. 2008). In flight tunnels test, the volatile chemical attracted females of the tephritid fruit fly parasitoid *Diachasmimorpha longicaudata*. The authors suggested that acetophenone could be a valuable monitoring tool in augmenting biological control using parasitoid species particularly species such as *D. longicaudata*.

Comments

Alyssum (*Lobularia maritima*) is deemed as an emerging environmental weed in Tasmania and as a potential environmental weed in other parts of southern Australia (Anonymous 2011). This widely cultivated garden ornamental has escaped cultivation and has become a weed of parks, footpaths, roadsides, waste areas, disturbed sites and coastal environs in southern and eastern Australia.

Origin/Distribution

It is native to the coastal areas of southern and western Europe and has naturalized elsewhere. It has been introduced into the New World and Australia.

Agroecology

Matthiola incana is a cool climate species, growing best in temperatures of 15–24 °C. It thrives in full sun to light shade and grows best in well-drained, moist, fertile, organic rich soil with a neutral or slightly alkaline pH range.

Edible Plant Parts and Uses

Its flowers are eaten as a vegetable or used as a garnish, especially with sweet desserts (Tanaka 1976; Facciola 1990). Studies reported that *M. incana* seeds contained oil rich (55–65 %) in omega-3 linolenic acid and could replace marine oils and thereby contribute beneficially to the human diet (Yaniv et al. 1999).

Botany

A biennial or perennial tomentose herb, 15–75 cm high, unbranched or with sparingly basal branching. Basal leaves rosulate; cauline leaves shortly petioled or sessile, oblanceolate, 3–16 cm long, (0.5–) 1–2 cm broad margin entire; base attenuate to cuneate, apex rounded (Plates 1 and 2). Racemes 10–30-flowered. Flower: sepals linear-lanceolate to

narrowly oblong, 10–15 by 2–3 mm; petals purple, violet, pink, red or white (Plates 1, 2 and 3), obovate to ovate, 20–30 by 7–15 mm, long clawed, apex rounded or emarginate; stamens 7–9, filaments 5–8 mm, anthers 2–4 mm; style 1–5 mm, stigma bilobed, erect, sessile. Siliquae (7–) 10–15 cm long, 2.5–4 mm wide, pubescent-glandular. Seed sub-orbicular, 2 mm across, brown, winged.

Nutritive/Medicinal Properties

Phytochemicals in Flowers

The flavonoid glycoside dactylin with the structure 5,7,3,4'- tetrahydroxy-3'-methoxyflavone-3-O-B-D-glucopyranoside was isolated from *M. incana* (Rahman and Khan 1962). The following phenolic compounds *p*-coumaric, caffeic, ferulic and sinapic acids and kaempferol and anthocyanin pigments were found in the flowers of healthy and virus-infected plants of *Matthiola incana* (Feenstra et al. 1963). In healthy red flowers larger amounts of cinnamic acids were present, bound to the acylated anthocyanins and other compounds and possibly also as free acids. When anthocyanin synthesis was blocked, the formation of cinnamic acids was also inhibited, except for small amounts of sinapic and ferulic acids. In anthocyanin-producing flowers of *Matthiola incana*, the presence of naringenin, naringenin 7-glucoside, dihydrokaempferol and dihydrokaempferol 7-glucoside was detected (Forkmann 1979). The four isolated compounds initiated anthocyanin synthesis after administration to acyanic flowers of genetically defined lines of *Matthiola incana* and *Antirrhinum majus*.

Nine anthocyanin pigments were reported to be present in the flowers of *M. incana*: 3-glucoside, 3,5-diglucoside and 3-feruloyl-*p*-coumaroylsambubioside-5-glucoside of pelargonidin and 3-glucoside, 3-sambubioside-5-glucoside, 3-caffeoylglucoside, 3-*p*-coumaroylglucoside, 3-*p*-coumaroylsambubioside and 3-caffeoylsambubioside of cyanidin (Harborne 1964, 1967; Seyffert 1960; Teusch et al. 1994). Anthocyanidin 3-glucosides and 3-sambubiosides acylated with 4-coumarate or caffeate were identified in flower extracts of lines of *Matthiola incana* with wild-type alleles of the gene *u* (Teusch et al. 1994). Accumulation of acylated 3-glycosides during bud development was correlated with acyltransferase activity. Four acylated cyanidin 3-sambubioside-5-glucosides were isolated from purple-violet flowers of *Matthiola incana* (Saito et al. 1995). Three acylated anthocyanins were cyanidin 3-O-(6-O-acyl-2-O-(2-O-sinapyl-β-

D-xylopyranosyl)-β-D-glucopyranosides)-5-O-(6-O-malonyl-β-D-glucopyranosides), in which the acyl group was *p*-coumaryl, caffeyl or ferulyl, respectively. The remaining pigment was free from malonic acid and was identified as cyanidin 3-O-(6-O-*trans*-ferulyl-2-O-(2-O-*trans*-sinapyl-β-D-xylopyranosyl)-β-D-glucopyranoside)-5-O-(β-D-glucopyranoside). Analysis of the anthocyanin constituents in 16 purple-violet cultivars revealed that they contained the above triacylated anthocyanins in variable amounts as main pigments. An aromatic pair of pigments containing sinapic and ferulic acids was considered to produce an important intramolecular effect, making bluish colours in these flowers. Ten acylated pelargonidin 3-sambubioside-5-glucosides were isolated from the red-purple flowers of *Matthiola incana*, and pelargonidin 3-glucoside was isolated from the brownish-red flowers of *Matthiola incana* (Saito et al. 1996). Seven of the ten pigments were determined to be pelargonidin 3-O-[2-O-(2-O-(acyl-I)-β-D-xylopyranosyl)- 6-O-(acyl-II)-β-D-glucopyranoside]-5-O-[6-O-(malonyl)-β-D-glucopyranoside], in which acyl moieties varied between sinapic, ferulic, caffeic and *p*-coumaric acids. The acylated pelargonidin 3-sambubioside-5-glucosides were present as the dominant pigments in the red-purple, salmon-pink and apricot colour cultivars. In contrast, pelargonidin 3-glucoside was present as a dominant anthocyanin in the copper colour cultivars, and also pelargonidin 3-sambubioside-5-glucoside was found as a minor pigment in the copper colour flowers.

Tatsuzawa et al. (2012) classified *M. incana* flower colours into eight groups, A–H, based on the hue values of their flowers and the major anthocyanin pigment found as follows: in violet flowers (hue values $b^*/a^* = -0.66$ and -0.69 , V 84A) of group A, cyanidin 3-dihydroxycinnamoylsambubioside-5-malonylglucosides; in purple flowers (-0.43 and -0.45 , P 75A) and red-purple flowers (-0.14 and -0.16 , RP 74A) of groups B and D, pelargonidin 3-dihydroxycinnamoylsambubioside-5-malonylglucosides; in red-purple flowers (-0.21 and -0.24 , RP 72A) of group C, cyanidin 3-monohydroxycinnamoylsambubioside-5-malonylglucosides; in red flowers

(0.05 and 0.06, RP 66A) of group E, pelargonidin 3-monohydroxycinnamoyl-sambubioside-5-malonyl-glucosides; in copper (0.23 and 0.16, R 54A) and peach (2.37 and 2.09, R38C) flowers of groups F and G, pelargonidin 3-glucoside; and a small amount of pelargonidin 3-glucoside was present in yellow flowers of group H.

Phytochemicals in Seeds

The fatty acid composition of *M. incana* seed oil was found to be myristic (2.60 %), palmitic (4.73 %), stearic (4.37 %), arachidic (2.50 %), lignoceric (0.73 %), oleic (32.17 %), linoleic (21.70 %), linolenic (10.70 %), erucic (13.10 %) and resin acids (7.40 %) (Rahman and Khan 1961). Sitosterol was found in the unsaponifiable matter.

Studies reported that *M. incana* seeds contained oil rich (55–65 %) in omega-3 ($n-3$) linolenic acid and elicited a beneficial effect when fed to animals by reducing cholesterol levels and increasing ($n-3$) fatty acid levels in the plasma (Yaniv et al. 1999). Cholesterol levels were significantly lowest in rats fed with diets rich in *M. incana* oil (27 % reduction) for 6 weeks, and triglycerides were significantly lower in rats receiving either *M. incana* or sunflower oil (36 % reduction). The contents of arachidonic acid and other ($n-6$) fatty acids were significantly the lowest in the liver and plasma of rats that had received *M. incana* oil. The levels of ($n-3$) fatty acids were significantly greater in both the liver and plasma of rats fed with *M. incana* oil. The ratio of ($n-3$)/($n-6$) long-chain fatty acids in the plasma was seven times higher in rats fed with *M. incana* oil than in those fed with sunflower oil and 6 times higher than in those fed with coconut oil. *M. incana*, being a rich source of ($n-3$) fatty acids, could replace marine oils and thereby contribute beneficially to the human diet. Earlier, Ecker et al. (1991) found the breeding lines of *Matthiola incana* tested differed significantly with respect to the levels of palmitic, oleic, linoleic and linolenic acids in the seed oils. Embryonic-stage heterosis in linolenic acid concentration was demonstrated by F1 hybrid

seeds, derived from mating horticulturally different lines. Linolenic acid content was negatively correlated with both oleic acid content ($R^2 = -0.85$) and linoleic acid content ($R^2 = -0.66$). A moderate negative correlation was found between the level of palmitic acid and that of oleic acid ($R^2 = -0.40$). None of the breeding lines or the F1 hybrids significantly passed the limit of 67 % linolenic acid. Studies by Heuer et al. (2005) found that total yield, seed number and oil content of *M. incana* seeds were not affected by salinity, whereas the content of omega-3 was significantly increased.

Traditional Medicinal Uses

The seeds are reported to be aphrodisiac, bitter, diuretic, expectorant, stimulant, stomachic and tonic (Chopra et al. 1986). An infusion has been employed to treat cancer, and when mixed with wine it has been used as an antidote to poisonous bites.

Other Uses

Matthiola incana is a popular ornamental plant. The flowers are often harvested for use in floral arrangements and decorative displays.

Comments

The plant is readily propagated from seeds.

Origin/Distribution

The species is native to Central America and Northern South America. It can be found from Mexico, Guatemala to Venezuela, as well as Brazil. It also can be found, cultivated in parts of America with warmer temperature such as Texas or California. It is widely cultivated elsewhere in tropical and subtropical areas and has escaped from cultivation and naturalized in many places.

Agroecology

A warm climate species, widely cultivated in tropical and subtropical areas from 75 to 2,000 m altitude. The plant is epiphytic or lithophytic. It grows well in full sun or light afternoon shade. The plant requires compost containing humus and adequate moisture during the dry months.

Edible Plant Parts and Uses

The mucilaginous flower is often eaten in a vegetable soup (Hu 2005; Li and Taylor 2007).

Botany

An epiphytic cactus with aerial roots. Stems erect, ascending, scandent or sprawling, profusely branched, old primary stems woody at the base and basal shoots terete, flattened to 2–6 m long; secondary stems flattened, leaflike, lanceolate to oblong-lanceolate, to 30 × 10–12 cm, thin; margins shallowly to deeply crenate and undulate (Plate 1). Areoles small, spineless. Flowers produced from flattened portions, to 30 cm long, 12–17 cm wide, funnel form, nocturnal, very fragrant. Receptacle tube 13–18 cm, base green, 4–9 mm across, slightly angled, with triangular to lanceolate scales 3–10 mm. Sepaloids often recurved, pale green or pinkish red, linear to oblanceolate. Petaloids white, oblanceolate to obovate, 7–10 × 3–4.5 cm. Stamens numerous with white, slender filaments, 2.5–5 mm and pale cream anthers, 3–3.5 mm. Style usually white (or orangey, red), 20–22 cm long and curved, stigmas 15–20, usually white, cream (or yellow), narrowly linear, 1.6–1.8 mm (Plates 1 and 2). Fruits are rare, purplish red, oblong, 16 × 5.7 cm. Seed 2–2.5 × 1.5 mm.

Nutritive/Medicinal Properties

The main aroma ingredients of *E. oxypetalum* flowers were found to be benzyl salicylate and methyl linoleate (Matsuura 2002). The flavonoid,

Plate 1 Flowers arising from the axils of the leaflike flattened stems (HF Chin)

Plate 2 Close-up of the flower (HF Chin)

kaempferol-3-*O*-L-rhamnopyranosyl-(1 → 6)-β-D-glucopyranoside was isolated from *E. oxypetalum* (Hsu et al. 2008).

Epiphyllum oxypetalum leaves were found to contain saponins, phenolic compounds, steroids, glycosides, tannins, terpenoids and resins, while reducing sugars, alkaloids, flavonoids, sterols, phlobatanins and acidic compounds were absent (Supendra and Khandelwal 2012). The leaves were found to have 14 mg/g protein, 4.6 mg/g lipids and 0.19 mg/g niacin dry basis. The acetone and petroleum ether leaf extracts showed inhibitory activity against *Escherichia coli* and *Staphylococcus aureus*, the acetone leaf extract against *Klebsiella pneumonia*, while the petroleum ether leaf extract against *Bacillus subtilis*. All the three leaf extracts were found to be ineffective against fungi (*Aspergillus niger*,

Aspergillus terreus, *Aspergillus oryzae* and *Rhizopus oryzae*) tested.

Epiphyllum oxypetalum extract was found to have moisturizing effect on the skin (Suzaki 2005). The extract increased ATP content, cell propagating activity and the yield of natural moisturizing factor in the epidermal cells.

Traditional Medicinal Uses

Epiphyllum oxypetalum is used in homeopathy and recommended for urinary tract infections, for heart conditions such as the crushing pain of angina and for spasmodic pain and haemorrhage (Yên 2008). In folk medicine, the plant has also been used to treat the spitting up of blood sputum and heavy or painful menstrual periods (Yên 2008). The juice of the plant has been used for bladder infections, shortness of breath and water retention. Applied externally, it has been used for rheumatism. It is also assumed to be an aphrodisiac.

Other Uses

Epiphyllum oxypetalum is by far the most popular and widely cultivated ornamental species from this genus of cacti.

Comments

The plant is easily propagated from the leaflike stem cuttings.

Mesua ferrea

Scientific Name

Mesua ferrea L.

Synonyms

Calophyllum nagassarium Burm. f., *Mesua nagassarium* (Burm. f.) Kosterm

Family

Calophyllaceae

Common/English Names

Ceylon Ironwood, Cobra's Saffron, Indian Rose Chestnut, Ironwood, Ironwood Tree, Ironwood Of Assam, Mesua, Poached Egg Tree, Sembawang Tree

Vernacular Names

Arabic: Narae-Kaisar

Bangladesh: Nageshwar

Burmese: Gungen, Kenga

Chinese: Tie Li Mu

Dutch: Ijzerhout

French: Arbe De Fer, Bois D'anis, Bois De Fer

German: Eisenholzbaum, Nagasbaum, Nagassamen

India: Nahar, Nahor, Nageshwar, Negeshvar, Nokte (Assamese), Nagesvara, Nagkesar, Punnaga (Bengali), Nagachampa, Nagkesara, Nagchampa, Pilunagkesar, Sachunagkeshara, Tamranagkesar (Gujarati), Nagakeshara, Nagchampa, Nagesar, Naghesar, Nagkesara, Nahar, Narmishka, Pila Nagkesara (Hindi), Nagakesari, Nagasampige (Kannada), Nagkesarah (Kashmiri), Churuli, Nagppu, Nagappovu, Nangaa, Nauga, Peri, Vainav, Veluthapalau (Malayalam), Nageshor (Manipuri), Nagakesara Nagchampa, Thorlachampa (Marathi), Nahar, Herhse (Mizo), Nageswar (Oriya), Nageswar (Punjabi), Champeryah, Gajakesara, Hema, Kesara, Naga, Nagakesara, Nagakeshara, Nagkesar, Nagakesarah, Nagkeshara, Nagkeshwar, Nagpushpa, Nagapuspah (Sanskrit), Charu-Nagapu, Nagappu, Nakecuram, Naugu, Naugaliral, Nagachampakam, Sirunagappoo, Tadinangu, Veillutta Champakam (Tamil), Kesaramu, Nagachampakamu, Nagakesaramu, Nagashappu (Telugu), Nagkesar, Narmishka, Narmushk (Urdu)

Indonesia: Nagasari Gede, Nagasari

Italian: Croco Di Cobra

Vietnamese: Vấp, Vếp

Origin/Distribution

Mesua ferrea is indigenous to the wet, tropical parts of Sri Lanka, India, southern Nepal, Burma, Thailand, Indochina, the Philippines, Malaysia and Sumatra.

Agroecology

In its native range, it occurs from near sea level to 2,300 m, as a canopy component in lowland evergreen forest, especially in river valleys, but also commonly features as an understory tree in montane evergreen or semievergreen forest. In Borneo, the species is associated with dipterocarps. It thrives best in a well-drained, moist, fairly fertile soil.

Edible Plant Parts and Uses

The ripe fruit (surli nuts) is edible, reddish and wrinkled when ripe and resembles chestnut in size, shape, rind, substance and taste. The oily seeds are edible when well cooked but unpleasant and not suitable as a cooking oil (Pongpangan and Poobrasert 1985). Young, tender leaves have a sour astringent taste and can be eaten raw. The flowers are edible and eaten in Thailand (Wessapan et al. 2007; Wetwitayaklung et al. 2008).

Botany

A medium to tall, evergreen, perennial tree growing 20 m to over 30 m high (Plate 1) with a buttressed base, smooth or weakly scaly, dark ash grey with a red-brown blaze bark and a trunk up to 2 m in diameter. Leaves are simple, opposite, narrow, oblong to lanceolate, blue-grey to dark green, 7–15 cm long and 1.5–3.5 cm wide, with a whitish underside (Plates 2 and 4). Juvenile leaves are reddish-yellowish pink. Flowers are terminal or axillary, fragrant, usually solitary, 4–7.5 cm across and borne on pedicels with small paired bracts. Flowers are bisexual with four white petals and a centre of numerous yellow stamens, free or connate only at the base (Plate 3). The ovary is superior with 1–2 axillary ovules, with a slender style and peltate to 4-lobed stigma. Fruit is an ovoid to subglobose, dehiscent capsule (Plate 4), often beaked, thinly woody containing 1–2 seeds.

Plate 1 Habit of tree

Plate 2 Flower buds and leaves

Plate 3 Flowers in bloom (HF Chin)

Nutritive/Medicinal Properties

Between 32 and 50 components were identified in the oils from the bark, leaves, buds and flowers (full bloom) of *Mesua ferrea*, accounting for

Plate 4 Fruits

82–97 % of the total yields (Choudhury et al. 1998). The bark oil was rich in (*E*)- α -bisabolene (31.3 %) and α -selinene (12.2 %). The predominant components in the oils of tender and mature leaves were α -copaene (19.3 and 99 %) and β -caryophyllene (18.8 and 26.0 %). The bud and flower oils also contained α -copaene (28.7 and 20.2 %) and in addition germacrene D (190 and 16.1 %).

Flower Phytochemicals

Mesuaferrone-b, a new biflavanone, was isolated from *Mesua ferrea* stamens (Raju et al. 1976). Petrol extracts of the stamens of *Mesua ferrea* afforded β -amyrin, β -sitosterol and a new cyclohexadione compound named mesuaferrol (Dennis et al. 1988).

A series of 4-alkyl and 4-phenyl 5,7-dihydroxycoumarins were extracted from *Mesua ferrea* blossoms (Verotta et al. 2004). The nine compounds were 5,7-dihydroxy-6-(isobutyryl)-8-(3-methylbut-2-enyl)-4-phenyl-2H-chromen-2-one (mesuol) (1); 5,7-dihydroxy-6-(2-methylbutanoyl)-8-(3-methylbut-2-enyl)-4-phenyl-2H-chromen-2-one (mammea A/AB) (1a); 5,7-dihydroxy-6-(3-methylbutanoyl)-8-(3-methylbut-2-enyl)-4-phenyl-2H-chromen-2-one (mammea A/AA) (mammeisin) (1b); 5,7-dihydroxy-6-(2-methylbutanoyl)-8-[(*E*)-3,7-dimethylocta-2,6-dienyl]-4-phenyl-2H-chromen-2-one (2); 5,7-dihydroxy-

6-(3-methylbutanoyl)-8-[(*E*)-3,7-dimethylocta-2,6-dienyl]-4-phenyl-2H-chromen-2-one (2a); 5,7-dihydroxy-8-(2-methylbutanoyl)-6-(3-methylbut-2-enyl)-4-phenyl-2H-chromen-2-one (mammea A/BB) (isomammeisin) (3); 5,7-dihydroxy-8-(3-methylbutanoyl)-6-(3-methylbut-2-enyl)-4-phenyl-2H-chromen-2-one (mammea A/BA) (3a); 5,7-dihydroxy-8-(2-methylbutanoyl)-6-[(*E*)-3,7-dimethylocta-2,6-dienyl]-4-phenyl-2H-chromen-2-one (4); 5,7-dihydroxy-8-(3-methylbutanoyl)-6-[(*E*)-3,7-dimethylocta-2,6-dienyl]-4-phenyl-2H-chromen-2-one (4a); 8,9-dihydro-5-hydroxy-8-(2-hydroxypropan-2-yl)-6-(2-methylbutanoyl)-4-phenylfuro[2,3-*h*]chromen-2-one (mammea A/AB cyclo F) (5a); 8,9-dihydro-5-hydroxy-8-(2-hydroxypropan-2-yl)-6-isobutyl-4-phenylfuro[2,3-*h*]chromen-2-one (mammea A/AD cyclo F) (5); 8,9-dihydro-5-hydroxy-8-(2-hydroxypropan-2-yl)-6-(3-methylbutanoyl)-4-phenylfuro[2,3-*h*]chromen-2-one (mammea A/AA cyclo F) (5b); 5,7-dihydroxy-4-(1-hydroxypropyl)-8-(2-methylbutanoyl)-6-(3-methylbut-2-enyl)-2H-chromen-2-one (assamene) (6); 5,7-dihydroxy-4-(1-hydroxypropyl)-8-(2-methylbutanoyl)-6-[(*E*)-3,7-dimethylocta-2,6-dienyl]-2H-chromen-2-one (surangin C) (6a); 8,9-dihydro-5-hydroxy-6-(2-methylbutanoyl)-4-phenyl-8-(prop-1-en-2-yl)furo[2,3-*h*]chromen-2-one (7); 8,9-dihydro-5-hydroxy-6-(3-methylbutanoyl)-4-phenyl-8-(prop-1-en-2-yl)furo[2,3-*h*]chromen-2-one (7a); 5-hydroxy-6-isobutyl-8,8-dimethyl-4-phenyl-2H-pyrano[2,3-*h*]chromen-2-one (mammea A/AD cyclo D) (mesuagin) (8); 5-hydroxy-8,8-dimethyl-6-(2-methylbutanoyl)-4-phenyl-2H-pyrano[2,3-*h*]chromen-2-one (mammea A/AB cyclo D) (mammeigin) (8a); 5-hydroxy-8,8-dimethyl-6-(3-methylbutanoyl)-4-phenyl-2H-pyrano[2,3-*h*]chromen-2-one (mammea A/AA cyclo D) (8b); 5-hydroxy-6-isobutyl-8-methyl-8-(4-methylpent-3-enyl)-4-phenyl-2H-pyrano[2,3-*h*]chromen-2-one (9); and 5-hydroxy-8-methyl-6-(2-methylbutanoyl)-8-(4-methylpent-3-enyl)-4-phenyl-2H-pyrano[2,3-*h*]chromen-2-one (9a). Fourteen major volatile components of the methanol flower extract of *Mesua ferrea* (Nordin et al. 2004).

Seed Phytochemicals

Two different samples of *Mesua ferrea* seed oil yielded coumarins mammeigin and mesuol as the main phenolic components (Bala and Seshadri 1971). The synthesis of mammeisin and mammeigin and also the conversion of mesuol into mesuagin were carried out.

Mesua ferrea seeds were found to contain total lipid (66.91–70.23 g %), moisture (4.02–5.05 g %), ash (1.46–1.50 g %), total protein (6.99–7.19 g %), water-soluble protein (2.98–3.11 g %), starch (5.51–5.85 g %), crude fibre (1.22–1.98 g %), carbohydrate (15.88–18.68 g %) and energy value (700.55–724.15 kcal/100 g) (Abu Sayeed et al. 2004).

Mesua ferrea seed oils were found to have the following physicochemical characteristics: specific gravity (0.9287–0.9312), refractive index (1.4690–1.4739), solidification point [–4.0–(–4.3)], pour point [–1.0–(–1.3)], cloud point (5.5–6.0), flashpoint (90–98), fire point (110–116), smoke point (44–47), iodine value (89.17–93.01), saponification value (199.03–206.40), saponification equivalent (271.80–281.86), acid value (9.64–11.87), free fatty acid (4.85–5.96), ester value (188.95–1.95.44), unsaponifiable matter (1.44–1.50), acetyl value (2.70–2.84), peroxide value (3.58–3.64), Reichert–Meissl value (5.852–6.031) and Polenske number (0.7891–0.8401) (Abu Sayeed et al. 2004). Glyceride classes were estimated to be monoglycerides (1.05–1.35 %), diglycerides (2.12–2.32 %) and triglycerides (87.65–89.50 %), whereas total lipid extracts were fractionated into neutral lipid (89.83–92.18 %), glycolipid (3.65–4.15 %) and phospholipid (1.98–2.68 %). Saturated and unsaturated fatty acids present in the oils were separated and amounted to be (27.40–29.11 %) and (65.85–68.31 %), respectively. The oil contained the highest amount of oleic acid 55.93 %, while linoleic acid, stearic acid and palmitic acid contents were found to be 13.68, 14.19 and 10.87 %, respectively. The oil also contained small amount of myristic acid (2.13 %) and arachidic acid (2.92 %). Konwer et al. (1989) found *M. ferrea* seed oil consisted of triglycerides of linoleic, oleic, palmitic and stearic acids.

Leaf Phytochemicals

Mesua ferrea leaves were found to contain total lipid (2.32–2.44 g %), moisture (65.12–72.19 g %), ash (2.60–2.71 g %), total protein (4.23–4.85 g %), water-soluble protein (1.47–2.01 g %), starch (3.06–3.27 g %), crude fibre (3.12–3.29 g %), carbohydrate (14.82–22.30 g %) and energy value (100.24–128.40 kcal/100 g) (Abu Sayeed et al. 2004).

Furano-naphthyl-hydroxy cyclohexyl type of compound was isolated from the ethyl acetate leaf extract of *Mesua ferrea* and identified as 12, 13-furano-8-hydroxy naphthyl-6- β -2',3',4',6'-tetrahydroxy-5',5' dimethyl cyclohexyl ether (Rahman et al. 2008).

Thirty-five components constituting 81.4 % total volatile components were obtained from *M. ferrea* leaf essential oil (Keawsaard and Kongtaweelert 2012). The oil comprised 60–7 % sesquiterpene hydrocarbons (60.7 %), diterpenes and triterpenes (0.4 %), terpene-related compounds (0.4 %), carboxylic acids (0.5 %), saturated hydrocarbons (0.3 %) and others (0.2 %). Major components were *trans*-caryophyllene (30.9 %), β -caryophyllene oxide (19.9 %), α -humulene (6 %), δ -cadinene (4.1 %), γ -muurolene (3.5 %), γ -cadinene (2.3 %), β -selinene (1.9 %), germacrene D (1.8 %) and β -bisabolene (1.6 %). Other minor components included (*Z*)-3-hexanol (0.1 %), linalool (trace), edulan I (trace), α -cubebene (0.3 %), α -ylangene (0.3 %), α -copaene (1.1 %), β -bourbonene (0.8 %), β -elemene (0.5 %), (*cis*)-caryophyllene (0.4 %), (+)-aromadendrene (0.7 %), (–)-alloaromadendrene (1.1 %), valence (1 %), α -selinene (1.1 %), α -muurolene (0.7 %), (*cis*)-calamenene (0.5 %), α -calacorene (0.3 %), caryophyllenyl alcohol (0.5 %), τ -muurolol (0.5 %), hexahydrofarnesyl acetone (0.5 %), *n*-hexadecanoic acid (0.5 %), phytol (0.2 %), 4,8,12,16-tetramethyl heptadecan-4-olide (0.1 %), hexadecanoic acid bis(2ethylhexyl) ester (0.1 %), heptacosane (0.1 %), squalene (0.2 %) and nonacosane (0.2 %).

Wood/Trunk/Root Phytochemicals

Two new yellow pigments, mesuaxanthone-A and mesuaxanthone-B, and the known euxanthone were isolated from the heartwood extracts of *Mesua ferrea* (Govindachari et al. 1967a). Mesuaxanthone-A was elucidated as 1,5-dihydroxy-3-methoxy-xanthone and mesuaxanthone-B as 1,5,6-trihydroxyxanthone. Ferruol A, C23H30O5, a new 4-alkylcoumarin isolated from the trunk bark (Govindachari et al. 1967b). The heartwood of *Mesua ferrea* was found to contain 1,5-dihydroxyxanthone (II), euxanthone 7-methyl ether (IV) and β -sitosterol, in addition to the two xanthenes previously isolated (Chow and Quon 1968). The following xanthenes dehydrocycloguanandin, calophyllin-B, jacareubin, 6-desoxy jacareubin, mesuaxanthone-A, mesuaxanthone-B and euxanthone were found in *M. ferrea* (Gopalakrishnan et al. 1980). A new xanthone, ferrxanthone, was isolated from the heartwood of *Mesua ferrea* and its structure determined as 1,3-dimethoxy-5,6-dihydroxyxanthone (Walia and Mukerjee 1984). The root bark extracts of *Mesua ferrea* afforded two new pyranoxanthenes, mesuaferrin A (1) and mesuaferrin B (2), and five other compounds—caloxanthone C (3), 1,8-dihydro-3-methoxy-6-methylanthraquinone (4), β -sitosterol (5), friedelin (6) and betulinic acid (7) (Teh et al. 2011).

Some of the pharmacological proprieties of the various plant parts are elaborated below.

Antioxidant Activity

Four edible flower extracts including *M. ferrea* elicited antioxidant activity in ABTS assay with the Trolox equivalent antioxidant capacity (TEAC) of 0.15–0.70 (Wessapan et al. 2007). Antioxidant activity in the flower extract was low, TEAC value=0.15, IC₅₀=61 μ g/50 μ l (Wetwitayaklung et al. 2008). Total polyphenol yield was 33.78 %, and total polyphenol content in the dried flowers was 1.94 g/100 g and in the crude methanol flower extract was 5.74 g/g.

The water and hot water extracts of *M. ferrea* flowers exhibited strong DPPH radical scavenging activity with EC_{50} =7.49, 6.95 μ g/ml, respectively, which were stronger than BHT (Makchuchit et al. 2010). The ethanol flower extract exhibited potent inhibitory activity on LPS-induced NO production in RAW 264.7 cells with IC_{50} value 26.32 μ g/ml.

The extracts of *M. ferrea* leaves showed good antioxidant activity with the ethanol (70 %) extract showing better activity than other extracts (methanol, ethyl acetate and hexane) in DPPH, superoxide and hydroxyl radical scavenging activities (Prasad et al. 2012). However, the antioxidant activities were lower than ascorbic acid. The leaf essential oil showed antioxidant in the DPPH assay with IC_{50} of 31.67 mg/ml (Keawsaard and Kongtaweelert 2012).

Analgesic Activity

The *n*-hexane extract of *M. ferrea* leaves administered orally to mice produced significant antinociceptive action against acetic acid-induced visceral pain models of nociception in mice (Hassan et al. 2006). In acetic acid-induced writhing model, the *n*-hexane, methanol and ethyl acetate partition fractions at a dose of 125 mg/kg body weight produced 36.08, 16.33 and 10.21 % reduction of writhing response. The extracts also produced 42.21, 19.63 and 17.06 % reduction of writhing response at a dose of 250 mg/kg body weight, respectively.

Immunomodulatory Activity

Mesul isolated from *M. ferrea* seed oil exhibited immunomodulatory activity in experimental animals (Chahar et al. 2012). In humoral immune response model, mesul evoked a significant dose-dependent increase in antibody titre values in cyclophosphamide-induced immunosuppression which was sensitized with sheep red blood cells (SRBC). In cellular immune response model, an increase in paw volume was recorded on the 23rd day in cyclophosphamide-induced

immunosuppressed rats treated with SRBC on the 21st day. Mesul restored the haematological profile in cyclophosphamide-induced myelosuppression model. Mesul potentiated percentage neutrophil adhesion in neutrophil adhesion test in rats and phagocytosis in carbon clearance assay.

Anticancer Activity

The crude methanol flower extract exhibited a strong cytotoxic activity (i.e. IC_{50} of 12.5 μ g/ml) towards T-lymphocyte leukaemia cell (Nordin et al. 2004). *M. ferrea* extract inhibited the growth of Ehrlich ascites carcinoma cells in Swiss albino mice (Masud Rana et al. 2004). The ethanol plant extract of *Mesua ferrea* exhibited promising in-vitro activity against human cholangiocarcinoma CL-6 cell line with survival of less than 50 % at the concentration of 50 μ g/ml and an IC_{50} value of 48.23 μ g/ml, for cytotoxicity activity (Mahavorasirikul et al. 2010). The extract also showed activity against human laryngeal (Hep-2) and human hepatocarcinoma (HepG2) cell lines. The leaf essential oil also exhibited anticancer activities against KB human oral carcinoma, MCF-7 breast cancer and small cell lung cancer NCI-H 187 cell lines with IC_{50} values of 24.02, 16.19 and 20.32 μ g/ml, respectively, but was not toxic to primate Vero cell line (Keawsaard and Kongtaweelert 2012).

Antimicrobial Activity

Mesul and mesuone from the seed oil were found to have antibacterial activity against *Staphylococcus aureus* (Chakraborty et al. 1959). Mesul was more active than mesuone against *Mycobacterium phlei*. Both were inactive against fungi tested. The crude methanol flower extract exhibited weak antimicrobial activities against bacteria, namely, *Staphylococcus aureus*, *Bacillus subtilis* and *Pseudomonas aeruginosa* (Nordin et al. 2004).

A series of 4-alkyl and 4-phenyl 5,7-dihydroxycoumarins (9 compounds) extracted from *Mesua ferrea* blossoms were found to be

potent antibacterials on resistant Gram-positive bacterial strains but were weak antiprotozoal agents against *Plasmodium falciparum* (Verotta et al. 2004).

Methanol flower extracts of five edible flowers including *M. ferrea* exhibited antibacterial effect against *Staphylococcus aureus* with MIC at 50–800 µg/ml (Wessapan et al. 2007). The methanol leaf extract of *Mesua ferrea* exhibited significant antibacterial effects in vitro against *Staphylococcus aureus*, *Bacillus* spp., *Escherichia coli*, *Lactobacillus arabinosus*, *Shigella* and *Salmonella* bacteria (Mazumder et al. 2003). In in-vivo tests, methanol flower extract of *Mesua ferrea* at concentrations of 100 and 200 µg/g of body weight significantly protected Swiss strain of albino mice against a virulent strain *Salmonella typhimurium* (Mazumder et al. 2004). The extract at 200 µg/g dosage significantly reduced the viable count of the *Salmonella* strain in the liver, spleen and heart blood of the extract-treated challenged mice. The flower extract exhibited in vitro antimicrobial efficacy against five different strains of *Salmonella* spp. with MICs of 50 µg/ml (Mazumder et al. 2005). The extract at 2 and 4 mg/mouse significantly protected Swiss albino mice against *S. typhimurium*. The ethanol/methanol seed extract was more active in-vitro against *Proteus mirabilis* and *Klebsiella pneumoniae* than the aqueous extract (Parekh and Chanda 2007). The methanol seed extract was effective in vitro against *Candida albicans* and *Trichosporon beigelii* at 125 µg/disc (Parekh and Chanda 2008). The extract was also effective against *Aspergillus candidus* (500 µg/disc), *Aspergillus flavus* (125 and 250 µg/disc), *Aspergillus niger* (125 and 250 µg/disc) and *Mucor hiemalis* (250 and 500 µg/disc).

The chloroform bark extract exhibited strong activity against Gram-positive *Streptococcus aureus* and Gram-negative *Escherichia coli*, but the leaf extracts exhibited mild to moderate activity against the tested bacteria (Ali et al. 2004). Nahar seed kernel oil emulsion demonstrated appreciable bacterial disinfestations at high concentration using the pour plate method (Adewale et al. 2011). At concentrations of 2 mg/ml or higher, total disinfestations were obtained with

little or no bacterial colonies seen after incubation. The ethanol leaf extract exhibited marked antibacterial property against selected microbes (*Escherichia coli*, *Pseudomonas aeruginosa*, *Bacillus subtilis* and *Staphylococcus aureus*) with the inhibition zones ranging from 16.0 to 18.05 mm for all the tested bacteria (Adewale et al. 2012). The MIC range of 2.5–0.625 mg/ml with MBC value of 5 mg/ml was obtained for the Gram-negative bacteria, while MIC range of 1.3–0.313 mg/ml with MBC value of 2.5 mg/ml was obtained for the Gram-positive bacteria. The leaves extract was found to be toxic to the Brine shrimps with LC₅₀ of 500 ppm (µg/ml), suggesting that the extracts may contain bioactive compounds of potential therapeutic and prophylactic significance.

The leaf essential oil exhibited antibacterial activity against *Escherichia coli* and *Staphylococcus aureus* with MIC values of 250 and 125 mg/ml, respectively (Keawsaard and Kongtaweelert 2012). Both leaf and fruit extracts of *M. ferrea* displayed good antibacterial activity against *Staphylococcus aureus* with a minimum inhibition concentration of 0.048 mg/ml (Aruldass et al. 2013). Both extracts are bacteriostatic at a minimum bacteriostatic concentration of 0.39 mg/ml. The treatment with the extracts caused extensive lysis of the cells, leakage of intracellular constituents and aggregation of cytoplasmic contents forming an open meshwork of the matrix.

Antiarthritic Activity

Studies demonstrated that *Mesua ferrea* seed extract protected rats against formaldehyde and complete Freund's adjuvant (CFA)-induced arthritis (Jalalpure et al. 2011). The body weight changes and haematological perturbations induced by CFA were maintained.

Antiinflammatory Activity

The xanthenes of *Calophyllum inophyllum* and *Mesua Ferrea*, namely, mesuaxanthone-A and

mesuaxanthone-B, exerted 37 and 49 % reduction in carrageenan-induced hind paw oedema upon oral administration in normal and adrenalectomized rats (Gopalakrishnan et al. 1980). In the granuloma pouch test, mesuaxanthone-A and mesuaxanthone-B elicited 46 and 49 % reduction in inflammation, respectively, and 47 % reduction was observed in the cotton pellet granuloma test.

Antivenom Activity

M. ferrea extract was one of several plant species that was found to have antidote activity against *Heterometrus laoticus* scorpion venom activity on fibroblast cell lysis (Uawonggul et al. 2006).

Antiulcerogenic Activity

The xanthones of *Calophyllum inophyllum* and *Mesua Ferrea*, namely, jacareubin and -desoxy jacareubin exhibited antiulcer activity in rats (Gopalakrishnan et al. 1980). The untreated control animals had extensive ulceration, haemorrhage and perforation; in contrast, the xanthone-pretreated animals exhibited only scattered areas of hyperaemia and occasional haemorrhagic spots.

Anticonvulsant Activity

The ethanol extract of *Mesua ferrea* inhibited maximum electroshock seizure (MES)-induced convulsions in albino mice (Tiwari et al. 2012). The extract also reduced the duration of hind limb tonic extension in a dose-dependent manner against MES model.

Wound Healing Activity

The ethanol extract of *Mesua ferrea* aerial parts in the form of ointment (5 and 10 % w/w) exhibited wound healing activity in both excision and incision models in albino rats (Choudhary 2012). The results suggested that the wound healing

activity of *Mesua ferrea* was due to its tannin content, which appeared to be responsible for wound contraction and increased rate of epithelialization.

CNS (Central Nervous System) Depressant Activity

The xanthones of *Calophyllum inophyllum* and *Mesua Ferrea*, namely, jacareubin (JR), dehydrocycloguanandin, calophyllin-B, 6-desoxy jacareubin, mesuaxanthone-A, mesuaxanthone-B and euxanthone, produced varying degrees of CNS depression characterized by ptosis, sedation, decreased spontaneous motor activity, loss of muscle tone, potentiation of pentobarbitone sleeping time and ether anaesthesia in mice and rats (Gopalakrishnan et al. 1980). None of the xanthones had any analgesic, antipyretic and anticonvulsant activities.

Antispasmodic Activity

The crude *M. ferrea* seed oil showed significant antispasmodic activity in the isolated rat ileum, but the purified oil was devoid of antispasmodic activity (Prasad et al. 1999).

Antihaemorrhoidal Activity

Paranjpe et al. (2000) conducted a 4-week clinical assessment of a multiherbal indigenous formulation administered orally as capsule to 22 patients with bleeding piles. The Ayurvedic formulation was composed of *Berberis aristata*, *Holarrhena antidysenterica*, *Picrorhiza kurroa*, *Mesua ferrea*, *Terminalia chebula*, *T. belerica* and *Embllica officinalis*. After 4 weeks, only 6 out of 22 patients still complained of bleeding. The formulation was well accepted and no adverse effects were reported.

Estrogenic/Progestational Activities

M. ferrea flower extract was found to have compounds which exhibited estrogenic and

progestational activity in humans and mice (Meherji et al. 1978). The results suggested that these compounds in *M. ferrea* may help to correct hormonal imbalance in menstrual disorders.

Traditional Medicinal Uses

The root, leaves, flowers and seeds are used in traditional medicine (CSIR 1962; Burkill 1966; Chopra et al. 1986; Khare 2004). *M. ferrea* traditionally is being used for its antiseptic, antiinflammatory, blood purifier, anthelmintic, cardiotonic, diuretic, expectorant, antipyretic, purgative, antiasthmatic, antiallergic and several other effects (Chahar et al. 2013). It is an ingredient of Ayurvedic formulations like Brahma Rasayana and Chyawanprash which are being used to improve immunity. Nagakeshara (*M. ferrea*) is a hot, dry digestive and good for fever, foul breath, sweats, scabies, skin eruptions, itching, small tumours, headache, blood and heart problems, sore throat, cough, hiccough, vomiting, excessive thirst, dysentery and bleeding piles (Joseph et al. 2010). The dried flower bud is antidysenteric and used for dysentery with mucus; the dried flowers are astringent, haemostatic, antiinflammatory and stomachic and used in cough, bleeding haemorrhoids and metrorrhagia (CSIR 1962; Chopra et al. 1986; Khare 2004). Fresh flowers are prescribed for excessive thirst, excessive perspiration, cough and indigestion. The leaves are applied to the head in the form of a poultice for severe colds. Oil from the seeds is used for sores, scabies, wounds and rheumatism. The root of this herb is often used as an antidote for snake poison.

Nagakesara in Indian system of medicine is used as deodorant, diaphoretic and stimulant (Anandakumar et al. 1986). It is a brain tonic appetizer, antiemetic, anthelmintic, aphrodisiac, diuretic and antidote. Nagakesara is mostly attributed to the stamens or the flowers of *Mesua ferrea*. Dried fruits of *Dillenia pentagyna* and dried fruiting inflorescence of *Cinnamomum wightii* are also used as Nagakesara in different regions of India.

In Peninsular Malaysia, the pounded kernels or seed oil have been used for poulticing wounds; flowers were used in a draught taken after childbirth and so is a root decoction (Burkill 1966). In Singapore, ashes of leaves were used as a lotion for sore eyes.

In Thailand, the seed is used as a cardiotonic and expectorant, for wounds and for its aroma (Wetwitayaklung et al. 2008).

Other Uses

Mesua ferrea is an important forest tree for timber production. The deep dark red wood is hard, heavy and suitably strong for all forms of heavy construction, railway sleepers, transmission posts, heavy-duty furniture, parquet flooring, posts and tool handles. The tree is also popularly planted as landscape, avenue trees or hedgerows. The incense sticks made from the flowers of this plant are popular worldwide for their intense fragrance. Fragrant stamens are used for stuffing pillows and cushions in the bridal beds.

The fraction of *M. ferrua* seed oil distilling between 200 and 300 °C may be used as fuel for diesel engines (Konwer et al. 1989). Studies showed that blending of *M. ferrea* seed oil with diesel up to 15 % (by volume) can be used in a compression-ignition (CI) engine without any major engine modification (Kushwah et al. 2008). Due to higher viscosity and density and low volatility of straight *M. ferrea* oil, it was found suitable for direct use in CI engine.

M. ferrea seed oil can be used in the manufacture of polyurethane paints, epoxy resins and nanocomposites. Three different polyester resins were synthesized from a purified seed oil (Dutta et al. 2004; Mahapatra and Karak 2004). The resins were formed by the reaction of monoglyceride obtained from the oil with phthalic and/or maleic anhydride and adipic acid separately. Poly(urethane amide) resins with varying ratio of NCO/OH (0.8:1–2:1) were synthesized from purified Nahar oil (*Mesua ferrea*) with toluene diisocyanate in the presence of dibutyl tin dilaurate as the catalyst (Dutta and Karak 2005). The results show better performance of the

poly(urethane amide) resins exhibited better performance compared to polyester or polyesteramide resins of the same oil. The study showed that these resins may hold promise for use as effective surface-coating materials. Thermogravimetric analysis demonstrated that the thermal stabilities of the cured resins prepared from *M. ferrea* seed oil increased with an increase in the NCO/OH ratios (Dutta and Karak 2006). The amounts of char residues at 550 °C were also found to be greater for higher NCO/OH ratios of the Nahar oil-modified polyurethane resins. A hyperbranched polyamine was utilized as an effective curing agent for a *Mesua ferrea* seed oil-based poly(ester-amide) resin (Mahapatra and Karak 2007). The hyperbranched polyamine not only enhance the rate of cross-linking reaction, but it also improved many desirable performance characteristics especially the thermostability, flame retardancy, hardness, impact strength, chemical resistance, etc. of the cured resin.

Two types of stoving paints had been prepared from *Mesua ferrea* seed oil-modified polyurethane ester (PUE) binder systems (Dutta et al. 2009a). Of the two test paints, the epoxy-modified PUE-based stoving paint was preferred. An epoxidized vegetable oil of *Mesua ferrea* seed was prepared and used as a reactive diluent for commercial BPA (bisphenol A)-based epoxy resin at different compositions and green nanocomposites (Das and Karak 2009). Epoxy-modified *Mesua ferrea* seed oil-based polyurethane nanocomposites also have the potential to be applicable as biomaterials (Dutta et al. 2009b). A bio-based sulphone epoxy resin (BPSE) was synthesized from the monoglyceride of *Mesua ferrea* seed oil, bis(4-hydroxyphenyl) sulphone, bisphenol A and epichlorohydrin (Das and Karak 2010). These bio-based epoxy/clay nanocomposites had improved flame retardancy and exhibited potential for multifaceted advanced applications. *Mesua ferrea* seed oil-based polyester was modified by methyl methacrylates to form a modified polyester for use as matrix for polyester resin/clay nanocomposite preparations with improved mechanical and thermal properties (Konwar et al. 2011).

Comments

The tree is sacred in India and is the national tree of Sri Lanka. The plant is propagated from seeds or cuttings.

Lonicera confusa

Scientific Name

Lonicera confusa (Sweet) DC.

Synonyms

Caprifolium confusum (Sweet) Spach, *Lonicera dasystyla* Rehder, *Lonicera multiflora* Champ. ex Benth., *Lonicera telfairii* Hook. & Arn., *Nintooa confusa* Sweet

Family

Caprifoliaceae

Common/English Names

Dasystyle honeysuckle, Tonkinese honeysuckle, Wild honeysuckle

Vernacular Names

Chinese: Mao Hua Zhu Ren Dong, Shui Ren Dong

French: Chevrefeuille Sauvage

Japanese: Kinginka

Korean: Keumeunhwa

Vietnamese: Kim ngân vôi nhám; Kim ngân đại

Origin/Distribution

The species is native to southern China (Guangdong, Guangxi, Yunnan, Hainan), Nepal and North Vietnam.

Agroecology

In its native range, it is found in scrub, margins of mixed forest, mountain slopes, river banks, roadsides, plains and terraced field banks from 300 to 800 m elevation. In North Vietnam, it is commonly found in limestone mountains of Ha Tay, Hoa Binh, Ha Nam and Ninh Binh (Le and Nguyen 1999). The species is hygrophilous and sun loving.

Edible Plant Parts and Uses

Flowers are used as food in China and Taiwan (Chau and Wu 2006).

Botany

A twining herb with greyish, pubescent or glabrous stems and branches, younger tender branches reddish and pubescent. Leaves are opposite, oval-lanceolate, 2–8 cm long by 1–4 cm wide with rounded bases and acuminate

Plate 1 Twining herb with ovate leaves

Plate 2 White flowers

apices, glabrous adaxially and pubescent abaxially (Plate 1) on furrowed, slightly flattened petioles (4–10 mm) without large sessile orange glands. Older leaves (lower) are lobate while young leaves are entire. Inflorescence consists of 2-flowered axillary cymes with fragrant white flowers (Plate 2), 2.5–4 cm by 1–2.5 mm across, changing to yellow after anthesis; flowers have acuminate minute bracts, short calyx tube, 2–2.5 mm long with short triangular calyx lobes; corolla white, tinged with purple-red near base, later yellowish, 2–3.5 cm, bilabiate, corolla tube 1.4–1.7 cm, outside slightly adpressed pubescent or glabrous, inside densely pubescent on upper lip; lobes oblong–lanceolate, 2 lateral lobes deep to over 1/3, lower lip narrowly linear; stamens 5 sub-equaling corolla, filaments sparsely pubescent at base, anthers linear; ovary densely to sparsely hirsute; style exserted, densely pubescent in

lower 1/3. Fruit is a globose berry turning black when ripe.

Nutritive/Medicinal Value

The plant contains saponins, tannin, luteolin, inositol, chlorogenic acid and a carotenoid—cryptoxanthin (Le and Nguyen 1999). Seven compounds were isolated from the dried flower buds of *L. confusa* and identified as rutin, quercetin, luteilin-7-*O*- β -D-galactoside, lonicerin, chlorogenic acid, β -sitosterol and tetratriacontane (Chai et al. 2004). Luteolin, chlorogenic acid, 3,5-dicaffeoylquinic acid and caffeic acid were detected in the dried flower buds, leaves and stems (three medicinal parts) of *Lonicera confusa* (Yao et al. 2006).

Ninety-three chemical components were separated from the volatile oil of fresh leaves in which 39 chemical components were identified (Xin et al. 2011). The main components were n-hexadecanoic acid (11.90 %), phytol (11.79) and 9,12,15-octadecatrienoic acid, methyl ester, (Z, Z, Z) (7.08 %). Eighty-eight chemical components were separated from the volatile oil from dry leaves in which 51 chemical components were identified. The main components were 1,6-octadien-3-ol, 3,7-dimethyl- (27.62 %), phytol (7.57 %) and 2, 6, 10, 14, 18, 22-tetracosahexaene, 2, 6, 10, 15, 19, 23-hexamethyl- (all-E) (4.70 %).

The flowers are used in traditional medicine for antiinflammation, antiallergy and detoxication to remove toxic heat and dispel wind-heat.

In Vietnam the flowers have been employed for the treatment of the following: carbuncles, boils, erysipelas, acute dysentery, pharyngitis, upper respiratory infection, epidemic febrile diseases, influenza, tonsillitis, acute conjunctivitis, enteritis, pyoderma, infected wounds and cervical erosion (Le and Nguyen 1999).

Other Uses

The flowers can be used to substitute *L. japonica* in herbal medicine.

Comments

The plant can be propagated from seeds and stem cuttings.

Lonicera japonica

Scientific Name

Lonicera japonica Thunb.

Synonyms

Caprifolium chinense S. Watson ex Loudon, *Caprifolium hallianum* Hort., *Caprifolium japonicum* (Thunb.) Dum. Cours., *Caprifolium roseum* Lam., *Lonicera brachypoda* DC., *Lonicera flexuosa* Thunb., *Lonicera japonica* var. *chinensis* (P.W. Wats.) Baker, *Nintooa japonica* (Thunb.) Sweet

Family

Caprifoliaceae

Common/English Names

Chinese Honeysuckle, Gold-And-Silver Flower, Hall's Honeysuckle, Honeysuckle, Japanese Honeysuckle, Woodbine

Vernacular Names

Brazil: Madressilva, Madressilva-Do-Japão
(Portuguese)

Chinese: Er Hua, Jin Yin Hua, Rěn Dōng, Rěn Dōng Téng, Shaung Hua

Cook Islands: Mangamangā Rima, Pitate Papa'Ā, Pītete Papa'Ā (Maori)

Czech: Zimolez Japonský

Danish: Gedebblad, Japansk Kaprifolie

Dominican Republic: Madreselva

Dutch: Japanse Kamperfoelie

French: Chèvrefeuille Du Japon, Clématite Du Japon

French Reunion: Chèvrefeuille

German: Japanisches Geißblatt, Japanische Heckenkirsche

Hawaiian: Honekakala

Icelandic: Flekkutoppur

India: Madhumati (Manipuri)

Italian: Caprifoglio Giapponese

Japanese: Nindo, Suikazura

Korean: Geumeunhwa, In-Dong, In Dong Deong Gul

Polish: Wiciokrzew Japoński

Portuguese: Madressilva, Orive Silva

Russian: Zhimolost' Japonskaia, Žimolost Japonskaja

Spanish: Madreselva

Swedish: Slingertny

Thai: Dtôn-Gim-Ngîng-Huay, Dtôn-Jin-Yîng-Hua, Dtôn Săai Nám Pêung, Dtôn-Yîm-dtang-dtîng

Vietnamese: Kim Ngân, Kim Ngân Nhật, Nhãn Đông

Welsh: Gwyddfid Japan

Origin/Distribution

The species is native to eastern Asia—northern and eastern China, Korea, Japan and Taiwan. It was introduced elsewhere and has become naturalized in Argentina, Australia, Brazil, Mexico, sub-Saharan Africa, New Zealand and much of the United States, including Hawaii, as well as a number of Pacific and Caribbean islands. Also it has become a major invasive species in North America.

Agroecology

Although a temperate species, it can grow in warm subtropical areas. It can climb over low-lying vegetation, shrubs and small trees and smother them. It occurs in mesic or wet areas, in both open and shaded areas, from sea level to 1,200 m elevation. It is adaptable to a diverse range of habitats and soil types from pH 4–8. It occurs in heathland, healthy woodland, damp sclerophyll forest, wet sclerophyll forest, riparian vegetation, edges of rivers and waterways, warm temperate rainforest, wasteland, scrub, thickets, parks and gardens. Soil types include sand, sandy clay, loamy clays, lateritic loams, granite, calcareous soils, silty alluvium, peat bogs and on soils derived from volcanic, sedimentary and metamorphic rock types. It has been reported to grow best on calcareous soils and moist forest soils, compared with excessively drained sandy soils or stony soils, where it is limited by moisture availability. It is tolerant of water-logged soils and is quite tolerant of seasonal droughts but is sensitive to frost which damages its shoots.

Edible Plant Parts and Uses

The flowers are used as a vegetable or made into syrup and puddings and also sucked for the sweet nectar (Facciola 1990). The flowers buds and leaves are also made into herbal teas (Kunkel 1984; Facciola 1990). The leaves are also eaten cooked or parboiled as vegetables (Facciola 1990).

Botany

Sprawling and twining, semi-deciduous to evergreen lianas with pithy stems, young stems pubescent climbing up to more than 10 m high on trees and shrubs. Leaves opposite on 5–13 mm long petioles, lamina ovate, elliptic, oblong or broadly lanceolate, 3–8 by 2–3 cm wide, apex acute or acuminate, base rounded or tapering, pubescent, becoming glabrate above, entire or young lower leaves sometimes lobed, glossy and deep green (Plate 1). Flowers, fragrant, pentamerous, two in axillary cymes, bracts 1–2 cm long, bracteoles suborbicular, 1 mm long; calyx of five joined deltoid sepals; corolla of five joined petals, bilabiate, lower lipped recurved, 3–5 cm, tube 1.5–3 cm long, white, turning yellowish (Plates 1 and 2) or tinged pink; stamens 5 free,

Plate 1 White and yellowish flowers and leaves

Plate 2 Close view of white flowers

exserted, adnate to perianth, alternating with petals, anthers versatile; ovary syncarpous, inferior 2-loculed each with 8–50 ovules, style one simple and glabrous. Fruit an indehiscent berry, fleshy, glossy, bluish-black, subglobose, 6–10 mm across. Seeds brown, ovoid or ellipsoid, 3 mm, shallowly pitted.

Nutritive/Medicinal Properties

Flower Phytochemicals

Phytochemical studies on *L. japonica* flowers revealed the presence of several saponins, triterpenoid saponins, monoterpenoids, sesquiterpenoids, cerebrosides, caffeoylquinic acids and esters, flavonoids, alkaloids, iridoid glycosides, secoiridoid glycosides, alcohols, aldehydes, ketones, oxygenated compounds, hydrocarbons, esters, phenolic acids and other phenolic compounds (Kawai et al. 1988a, b; Son et al. 1992, 1994a; Ikeda et al. 1994; Schlotzhauer et al. 1996; Kakuda et al. 2000; Peng et al. 2000; Teng et al. 2000; Kumar et al. 2005, 2006; Li and Li 2005; Song et al. 2006; El-Kashoury et al. 2007; Qian et al. 2007b; Lin et al. 2008; Qi et al. 2009; Tang et al. 2009; Li et al. 2009c; Lee et al. 2010a, b; Wang et al. 2009; Wang and Yang 2011; Zhou et al. 2012). Twenty-seven compounds were identified in *L. japonica* flowers among the three developmental stages (freshly opened, overnight and 24 hours) (Schlotzhauer et al. 1996). Germacrene D (28.33–53.17 %) was a major component at all stages; linalool and α -farnesene appeared in high concentrations in fresh and 24 hours flowers but were greatly reduced in overnight flowers. The latter, however, contained elevated levels of phenylpropanoid biosynthesized compounds, suggesting a marked diurnal influence on the biosynthesis of volatile flower constituents involving two modes of action: phenylpropanoid and lipxygenase derivation. A total of 41 compounds including 13 iridoid glycosides, 11 phenolic acids, 7 saponins and 10 flavonoids were identified in a methanol extract of *L. japonica* flowers (Qi et al. 2009). A triterpenoid saponin, together with a known saponin, was isolated from the

flowers, and their structures were deduced to be 3- β -D-glucopyranosyl-(1 \rightarrow 4)- β -D-glucopyranosyl-(1 \rightarrow 3)- α -L-rhamnopyranosyl-(1 \rightarrow 2)- α -L-arabinopyranosyl hederagenin 28-O- β -D-glucopyranosyl-(1 \rightarrow 6)- β -D-glucopyranoside and 3- α -L-rhamnopyranosyl-(1 \rightarrow 2)- α -L-arabinopyranosyl hederagenin 28-O- α -L-rhamnopyranosyl-(1 \rightarrow 2)-[β -D-xylopyranosyl-(1 \rightarrow 6)]- β -D-glucopyranoside, respectively (Teng et al. 2000).

Five caffeoylquinic acids and esters, 3-caffeoylquinic acid (57 mg), 3-caffeoylquinic acid methyl ester (132 mg), 3,5-dicaffeoylquinic acid (210 mg), 3,5-dicaffeoylquinic acid methyl ester (34 mg) and 3,5-dicaffeoylquinic acid butyl ester (20 mg), were isolated from 1.35 kg of dried flowers and buds of *L. japonica* (Peng et al. 2000). Two secoiridoid glycosides, loniceracetals A and B, were isolated in very small amounts, together with ten known iridoid glycosides, from the flower buds of *Lonicera japonica* (Kakuda et al. 2000). The content of chlorogenic acid in flowers of *Lonicera macranthoides* (4.00–4.52 %) was higher than that in *Lonicera japonica* (2.20–2.46 %) (Zhou and Tong 2003). Nine compounds, namely, loganin, sweroside, 7-epi-vogeloside, 7-epi-loganin, secoxyloganin, caffeic acid, *p*-hydroxybenzoic acid, β -sitosterol and daucosterol, were isolated from the flower buds (Li and Li 2005). Caffeic acid, chlorogenic acid, methyl ester of chlorogenic acid, triclin, apigenin, 4'-O-methyl ether of apigenin (acacetin), quercetin and 3'-O-methyl ether of quercetin were isolated from *Lonicera japonica* flowers (Phan et al. 2005). Eight iridoid glycosides, namely, sweroside, 7-O-ethyl sweroside, 7-epi-vogeloside, secoxyloganin, secoxyloganin 7-butyl ester, dimethyl-secologanoside, centauroside and loganin, were found in the flower buds of five *Lonicera* species including *L. japonica* (Song et al. 2006).

Six novel cerebrosides, lonijaposides A₁–A₄, B₁ and B₂, were isolated from the flowers of *Lonicera japonica* (Kumar et al. 2006). Three pyridinium inner salt alkaloid-coupled secoiridoids, lonijaposides A–C together with seven known iridoids, were isolated from *Lonicera japonica* flower buds (Song et al. 2009). Thirteen bioactive compounds comprising iridoids (loganin, sweroside,

secoxyloganin and centauroside), phenolic acids (chlorogenic acid, caffeic acid, 4,5-di-*O*-caffeoylquinic acid and 3,4-di-*O*-caffeoylquinic acid) and flavonoids (rutin, hyperoside, quercetin-3-*O*-glucoside, luteolin-7-*O*-glucoside and lonicerin) were found in the flowers (Qian et al. 2007b). A new triterpenoid glycoside, oleanolic acid 28-*O*- α -L-rhamnopyranosyl-(1 \rightarrow 2)-[β -D-xylopyranosyl(1 \rightarrow 6)]- β -D-glucopyranosyl ester, along with eleven known compounds, including chrysoeriol, luteolin, 5-hydroxymethyl-2-furfural, caffeic acid, protocatechuic acid, chrysoeriol 7-*O*- β -D-glucopyranoside, isorhamnetin 3-*O*- β -D-glucopyranoside, kaempferol 3-*O*- β -D-glucopyranoside, quercetin 3-*O*- β -D-glucopyranoside, hederagenin 3-*O*- α -L-arabinopyranoside and luteolin 7-*O*- β -D-glucopyranoside, were isolated from the ethyl acetate fraction of the methanol extract of *L. japonica* flowers (Choi et al. 2007). Two new triterpenoid saponins, loniceroid D and loniceroid E, along with seven known compounds, chlorogenic acid, sweroside, vogeloside, *epi*-vogeloside, loniceroid A, loniceroid B and loniceroid C, were isolated from the dry flowers and buds of *Lonicera japonica* (Lin et al. 2008).

A novel cyclic peroxide shuangkangsu was obtained from the water extract of *L. japonica* buds, and its structure was elucidated as 5,8-divinyl-1,4-dihydro-1,4-di-*O*- β -D-glucopyranosyl-2,3-dioxane (Yu et al. 2008). Li et al. (2009a) synthesized four novel cyclic peroxide glucosides 15a, 15b, 16a and 16b, optically pure analogues of shuangkangsu, an antiviral natural product with an unusual skeleton isolated from the buds of *Lonicera japonica*. They also synthesized four optically pure cycloperoxide glucosides 9a, 9b, 10a and 10b, analogues of shuangkangsu (Tang et al. 2009). A total of 41 compounds including 13 iridoid glycosides, 11 phenolic acids, 7 saponins and 10 flavonoids were identified in a methanol flower extract of *L. japonica* (Qi et al. 2009). Ten bioactive components were identified in the dried flowers: chlorogenic acid, luteolin-3-*O*-glucoside and 4,5-di-*O*-caffeoylquinic acid, 4-caffeoylquinic acid, quercetin-3-*O*-glucoside, lonicerin, 3,5-di-*O*-caffeoylquinic acid, 3,4-di-*O*-caffeoylquinic

acid, caffeic acid and rutin (Qian et al. 2008). All the compounds had binding interaction with bovine serum albumin (BSA). The binding degrees of the compounds to BSA ranged from 4.8 to 61.2 (0.3 mM BSA) and from 11.1 to 76.2 % (0.6 mM BSA), respectively. Serum albumins are the most abundant proteins in the circulatory system of a wide variety of organisms and have the physiological function to maintain the osmotic pressure and to transport a wide variety of endogenous and exogenous compounds, such as fatty acids, steroids and drugs.

Thirty-three constituents were detected and characterized in the flower buds of *Lonicera* spp. (*L. japonica* Thunb., *L. hypoglauca* Miq., *L. hypoglauca* Miq. subsp. *nudiflora* Hsu et H. J. Wang, *L. fulvotomentosa* Hsu et S. C. Cheng, *L. nubium* Hand.-Mazz., *L. confusa* (Sweet) DC., *L. pampanini* Lévl.) comprising six caffeoylquinic acids (CQA), 3-*O*-caffeoylquinic acid (3-CQA), 4-*O*-caffeoylquinic acid (4-CQA), 5-*O*-caffeoylquinic acid (5-CQA), 3,5-di-*O*-caffeoylquinic acid (3,5-diCQA) and 4,5-di-*O*-caffeoylquinic acid (4,5-diCQA) (including caffeic acid); eight flavonoids, quercetin-3-*O*-rutinoside (rutin), quercetin-3-*O*-galactoside (hyperoside), luteolin-7-*O*-glucoside, kaempferol-3-*O*-glucoside, isorhamnetin-3-*O*-glucoside, luteolin-*O*-dihexoside, quercetin and luteolin; and eight iridoid glycosides, loganin, secologenic acid (swertiamarin), sweroside, secoxyloganin, *epi*-vogeloside, 7-*O*-ethyl sweroside or isomer and aldosecologanin and the rest unknown (Li et al. 2009c). From the polar fractions of a 70 % ethanol flower extract, ten constituents were isolated and identified as iridoid glycosides: 7-dehydrologanin (7-ketologanin), secologanin dimethyl acetal, (*E*)-aldosecologanin (centauroside), dimethyl secologanoside, secoxyloganin, *epi*-vogeloside, uracil, D-mannitol, sucrose and 1-*O*- β -D-glucopyranosyl-(2S,3S,4R,8*E/Z*)-2-[(2R)-2-hydroxy(docosanoyl, tricosanoyl, tetracosanoyl, pentacosanoyl)amino]-8-octadecene-1,3,4-triol (Lee and Kim 2010).

Thirteen phenolic constituents, luteolin; protocatechuic acid; caffeic acid; flavoyadorinin-B; 4,5-dicaffeoylquinic acid; luteolin 7-*O*- β -D-glucopyranoside; 3,5-dicaffeoylquinic acid methyl

ester; methyl chlorogenate; quercetin 3-*O*- β -D-glucopyranoside; 3,5-dicaffeoylquinic acid; rhoifolin; chlorogenic acid; and a novel phenolic glucoside benzoate, vanillic acid 4-*O*- β -D-(6-*O*-benzoylglucopyranoside), were isolated from the flower buds of *Lonicera japonica* (Lee et al. 2010a).

Twenty compounds were isolated from the dried buds of *L. japonica* and identified as sophoricoside, luteolin-7-*O*- β -D-glucopyranoside; rutin; quercetin; 3,5-*O*-dicaffeoylquinic acid methyl ester; 4,5-*O*-dicaffeoylquinic acid methyl ester; 3,4-*O*-dicaffeoylquinic acid methyl ester; 4,5-dicaffeoylquinic acid; 3,4-dicaffeoylquinic acid; chlorogenic acid; *epi*-vogeloside; sweroside; vogeloside; secoxyloganin; macranthoidin A; macranthoidin B; loniceroside A; loniceroside B; loniceroside C; and dipsacoside B (Wang and Yang 2011). Four new N-containing iridoid glycosides, lonijapospinoside A, L-phenylalaninosecologanin B, L-phenylalaninosecologanin C and dehydroprolinoylloganin A, were isolated from the flower buds (Zheng et al. 2012). Fifteen homosecoiridoids were isolated from the flower buds of *Lonicera japonica* (Yu et al. 2011). Compounds 1–4, designated as loniphenyruviridosides A–D, possessed unprecedented skeletons featuring phenylpyruvic acid-derived moieties coupled with an iridoid or a secoiridoid nucleus. Compounds 5–15 (lonijaposides D–N) represented additional examples of the unusual pyridinium alkaloid-coupled secoiridoids (lonijaposides A–C).

The following compounds were identified from the essential oil of *L. japonica* flowers: pinene; hexene-1; *cis*-3-hexanol-1; *cis*-2-methyl-2-vinyl-(α -hydroxy-isopropyl)-tetrahydrofuran; *trans*-2-methyl-2-vinyl-(α -hydroxy-isopropyl)-tetrahydrofuran; (–) *cis*-2,6,6-trimethyl-2-vinyl-5-hydroxytetrahydropyran; linalool; geraniol; α -terpineol; benzyl alcohol; β -phenylethyl alcohol; carvacrol; and eugenol (Wu and Fang 1980). Ji et al. (1990) identified 47 compounds in the essential oil of *L. japonica* flowers including ethyl palmitate and linalool. Twenty and thirty monoterpenoids and sesquiterpenoids were identified from the essential oil of the dry flower and fresh flower, respectively (Wang et al. 1992). The major constituents were linalool, geraniol,

aromadendrene and eugenol. One hundred and fifty compounds, made up of 36 hydrocarbons, 28 alcohols, 21 aldehydes, 12 ketones, 38 esters and 15 miscellaneous, were identified, and the important components that characterized the volatiles of honeysuckle flowers were determined to be linalool, (Z)-jasnone, (Z)-jasmin lactone, methyl jasmonate and methyl epi-jasmonate (Ikeda et al. 1994). Sixty compounds were identified among the volatiles in the flowers prepared by the two methods, floral absolute volatiles (FAV) and hydrodistilled/hexane-extracted volatiles (HHV) (El-Kashoury et al. 2007). Linalool was the major constituent in both cases and was higher in the floral absolute volatiles (47.92 %). Nerolidol, 4-terpineol, *cis*-jasnone, *cis*-3-hexenyl tiglate, methyl palmitate and *trans*-linalool oxide were detected in lesser but appreciable quantities in both samples. The oxygenated compounds were dominant in both cases with alcohols as major (63.43 and 37.86 %), followed by esters (16.97 and 32.9 %) in FAV and HHV, respectively. Aldehydes were present in higher proportions in HHV (6.77 %) than in FAV (2.98 %), while ketones were higher in FAV (3.71 %) than HHV (1.76 %). *cis*-Jasnone, the principle component of the essential oil of jasmine flowers, was present in relatively high concentrations in FAV (3.27 %) and in lesser amounts in HHV (1.32 %). The profile of the volatiles in FAV were as follows: α -farnesene (1.195 %), *trans*-3-hexen-1-ol (0.21 %), *cis*-3-hexen-1-ol (0.41 %), *cis*-sabinene hydrate (2.58 %), linalool (47.92 %), 4-terpineol (3.67 %), *p*-menth-1-en-8-ol (0.78 %), nerol (0.30 %), geraniol (0.38 %), nerolidol (7.18 %), lilac aldehyde (1.86 %), methyl azealate semialdehyde (0.77 %), palmitic aldehyde (0.35 %), *cis*-jasnone (3.27 %), heptadecanone (0.44 %), *cis*-3-hexenyl tiglate (3.92 %), methyl jasmonate (1.18 %), methyl epi-jasmonate (0.26 %), methyl palmitoleate (0.91 %), ethyl palmitate (0.25 %), methyl linolenate (7.18 %), ethyl linolenate (0.19 %) and *trans*-linalool oxide (1.23 %) (El-Kashoury et al. 2007). The profile of the volatiles in HHV were as follows: *p*-cymene (0.56 %), α -copaene (0.10 %), β -bourbonene (0.67 %), germacrene D (0.47 %), pristane

(0.12 %), *n*-pentadecane (0.21 %), *n*-heptadecane (0.16 %), *n*-octadecane (0.21 %), *n*-docosane (0.23 %), *n*-tricosane (0.40 %), *n*-tetracosane (0.13 %), *n*-pentacosane (0.30 %), *cis*-3-hexen-1-ol (0.93 %), 2-methyl-5-hexanol (0.34 %), 6-hepten-1-ol-5-methyl (0.13 %), linalool (22.08 %), 1-terpineol (0.34 %), 4-terpineol (3.34 %), *p*-menth-1-en-8-ol (2.81 %), *cis*-piperitol (0.11 %), geraniol (0.57 %), nerolidol (6.72 %), α -cadinol (0.16 %), alfol 14 (0.33 %), *n*-hexanal (0.81 %), neral (0.28 %), geranial (0.20 %), methyl azelate semialdehyde (2.25 %), myristaldehyde (0.46 %), palmitic aldehyde (2.77 %), *cis*-jasmane (1.32 %), *trans*-geranyl acetone (0.44 %), methyl octanoate (0.35 %), *cis*-3-hexenyl tiglate (3.15 %), methyl laurate (0.30 %), methyl jasmonate (0.33 %), methyl pentadecanoate (0.32 %), methyl palmitoleate (18.26 %), ethyl-9-hexadecanoate (0.10 %), ethyl palmitate (0.43 %), methyl heptadecanoate (0.20 %), methyl oleate (3.57 %), methyl stearate (0.98 %), arachidic acid methyl ester (0.17 %), hexadecanoic acid, cyclohexyl ester (0.09 %), *trans*-2,3-epoxyoctane (0.20 %), lavender lactone (0.09 %), *cis*-linalool oxide (3.39 %), *trans*-linalool oxide (2.51 %) and caryophyllene oxide (0.19 %) (El-Kashoury et al. 2007).

Wang et al. (2009) reported that the primary components of the volatile oil from flowers were linalool (0.15–15.35 %), linalool oxide (0.09–6.53 %), geraniol (0.24–8.17 %) and α -terpineol (0–10.57 %), and obvious variations in components of the volatile oil were observed at six different developmental stages. The chlorogenic (2.7–3.5 %) and total flavonoid contents (11.6–13.2 %) of *L. japonica* flowers varied with the different flowering stages (Li et al. 2009b). The volatile oil samples of the flowers were found to have three types of compounds, *n*-diolefins, fatty acids and steroids. These included nonacosane (40 %), hentriacontane (20 %), vitamin E (8.15–10.43 %), γ -5-sitostene-3-ol (4.90–6.9 %), stigmasta-5,2-diene-3-ol (1.06–4.10 %) and campesterol.

Thirty-nine compounds representing 92.34 % of the total oil were identified from the flower essential oil, of which *trans*-nerolidol (16.31 %), caryophyllene oxide (11.15 %), linalool (8.61 %),

p-cymene (7.43 %), hexadecanoic acid (6.39 %), eugenol (6.13 %), geraniol (5.01 %), *trans*-linalool oxide (3.75 %), globulol (2.34 %), pentadecanoic acid (2.25 %), viridiflorol (1.83 %), benzyl alcohol (1.63 %) and phenylethyl alcohol (1.25 %) were the major compounds (Rahman and Kang 2009). Minor components included citronellyl acetate (0.97 %), geranylacetone (0.92 %), hexahydrofarnesyl acetone (0.87 %), α -cadinol (0.85 %), tetradecanoic acid (0.85 %), dodecanal (0.83 %), aromadendrene (0.82 %), 1,8-cineole (0.81 %), juniper camphor (0.76 %), octadecanoic acid (0.75 %), *p*-cymene (7.43 %), acetophenone (0.74 %), 1-octen-3-ol (0.70 %), β -ionone (0.70 %), *cis*-linalool oxide (furanoid) (0.69 %), spathulenol (0.69 %), *cis*-4-heptenal (0.66 %), α -terpineol (*p*-menth-1-en-8-ol) (0.65 %), β -caryophyllene (0.65 %), *cis*, *trans*-farnesol (0.68 %), *cis*-jasmane (0.58 %), dodecane (0.55 %), geranyl acetate (0.54 %), undecanal (0.52 %), elemol (0.52 %), epiglobulol (0.50 %) and decanal (0.46 %).

Constituents of the essential oil from the flower buds comprised 87.62 % monoterpenoids and 5.88 % sesquiterpenoids with a predominance of estragole (80.17 %) and were identified as follows: 1-octen-3-ol (0.04 %), β -pinene (0.03 %), (D)-limonene (0.175 %), 1, 8-cineole (0.31 %), benzyl alcohol (0.085 %), acetophenone (0.34 %), linalool (6.05 %), phenylethyl alcohol (0.25 %), α -terpineol (0.12 %), linalool acetate (0.28 %), (Z)- β -damascenone (0.16 %), α -cubebene (0.12 %), eugenol (0.23 %), β -geranyl acetate (0.12 %), β -caryophyllene (0.25 %), β -gurjunene (0.36 %), germacrene D (3.17 %), α -selinene (0.31 %), α -farnesene (1.01 %), β -cadinene (0.12 %), elemol (0.22 %), caryophyllene oxide (0.15 %), α -cadinol (0.11 %) and juniper camphor (0.18 %) (Zhou et al. 2012).

Han et al. (2012) reported that the volatile oil obtained from subcritical R134 extraction from *L. japonica* flowers comprised a complex mixture consisting of hydrocarbons, terpenes and esters. Twenty-seven compounds were identified. The oil contained 2.791 % of alkene and alkane which were probably derived from fatty acids. The major components in the volatile oil were fatty acids which represented 47.013 % of the

total oil composition. The major fatty acids were n-hexadecanoic acid (19.117 %), 9,12-octadecadienoic acid (9.062 %) and 9,12,15-octadecatrien-1-ol (18.432 %). In addition, the volatile oil also contained 29.340 % fatty acid ester, namely, hexadecanoic acid methyl ester (3.529 %), hexadecanoic acid ethyl ester (1.835 %), 9,12-octadecadienoic acid methyl ester (3.471 %), 9,12,15-octadecatrienoic acid methyl ester, (Z,Z,Z)- (4.662 %), octadecanoic acid methyl ester (0.793 %), linoleic acid ethyl ester (3.556 %), 7,10,13-hexadecatrienoic acid, methyl ester (4.622 %), octadecanoic acid, ethyl ester (0.923 %), eicosanoic acid, methyl ester (0.351 %), 11,14-eicosadienoic acid, methyl ester (0.314 %), docosanoic acid, methyl ester (0.664 %), nonadecanoic acid, ethyl ester (0.479 %), tetracosanoic acid, methyl ester (4.151 %) and octadecanoic acid (0.402 %). Other components included the following: tetradecanal (0.190 %), 2-heptadecanone (1.028 %), tricosane (0.886 %), eicosane (0.347 %), pentacosane (0.902 %), 7-methyl-Z-tetradecen-1-ol acetate (1.091 %), 17-pentatriacontene (0.393 %), triallylmethylsilane (0.656 %), *E*-15-heptadecenal (1.922 %) and squalene 1.235 %.

Secoiridoid sulfonates 1–3 were isolated from the 50 % ethanol/aqueous extract of the sulfiting-processed *Lonicera japonica* flower buds (Li et al. 2012). Analyses of the different samples of *Lonicera japonica* flowers obtained by various process techniques suggested that the sulphur fumigation led to the decrease of secologanic acid and the formation of secologanic acid-derived sulfonate 1 and its derivatives 2, 2a and 3 in the crude materials, which revealed that sulphur fumigation, the traditional process technique, could alter the phytochemical profiles of some Chinese herbal medicine.

Aerial Parts/Cell Suspension Culture Phytochemicals

From the aerial parts of *Lonicera japonica*, 12 triterpenoidal saponins having oleanolic acid and hederagenin as aglycones were isolated (Kawai et al. 1988b). Saponins 1,2,4,5,8 and 10

had the hederagenin as aglycones. Saponins 3, 1 and 7 had oleanolic acid as aglycone along with methyl sugars. Saponins 2, 3,7 and 8 contained the glucosyl-arabinosyl-type saponins, while saponins 4,9, 10 and 11 contained the rhamnosyl-arabinosyl-type saponins and 12 the acetyl derivative. The structures of four new saponins, 6,9,11 and 12, were established to be 3-*O*- α -L-arabinopyranosyl-28-*O*-[β -D-glucopyranosyl(1 \rightarrow 6)- β -D-glucopyranosyl]oleanolic acid; 3-*O*-[α -L-rhamnopyranosyl(1 \rightarrow 2)- α -L-arabinopyranosyl]-28-*O*- β -D-glucopyranosyl hederagenin; 3-*O*-[α -L-rhamnopyranosyl(1 \rightarrow 2)- α -L-arabinopyranosyl]-28-*O*-[β -D-glucopyranosyl(1 \rightarrow 6)- β -D-glucopyranosyl]oleanolic acid; and 3-*O*-[α -L-rhamnopyranosyl(1 \rightarrow 2)- α -L-arabinopyranosyl]-28-*O*-[6-acetyl- β -D-glucopyranosyl(1 \rightarrow 6)- β -D-glucopyranosyl] hederagenin, respectively. A new iridoid glucoside, epi-vogeloside, was isolated along with secologanin dimethyl acetal, loganin and vogeloside from hot aqueous extract of aerial parts of *Lonicera japonica* (Kawai et al. 1988a). Fresh young shoots were found to be a rich source of secoxyloganin that could be converted into secologanin (Mehrotra et al. 1988).

Seven flavonoids hydrnocarpin, quercetin, ochnaflavone, ochnaflavone 4'-*O*-methylether, astragalin, isoquercitrin and rhoifolin were isolated from the aerial parts of *Lonicera japonica* (Son et al. 1992). Two new triterpenoid saponins, lonicerin A and B, were isolated from the aerial parts of *Lonicera japonica*, and their structures were established as 3-*O*- α -L-arabinopyranosyl hederagenin 28-*O*- α -L-rhamnopyranosyl (1 \rightarrow 2)-[β -D-xylopyranosyl(1 \rightarrow 6)]- β -D-glucopyranosyl ester and 3-*O*- α -L-rhamnopyranosyl (1 \rightarrow 2)- α -L-arabinopyranosyl hederagenin 28-*O*- α -L-rhamnopyranosyl (1 \rightarrow 2)-[β -D-xylopyranosyl(1 \rightarrow 6)]- β -D-glucopyranosyl ester, respectively (Son et al. 1994a). Two flavonoids, diosmetin 7-*O*-glucoside and lonicerin, and an iridoid vogeloside were isolated from the aerial parts (Son et al. 1994b). Four flavonoids, namely, luteolin-7-*O*- α -D-glucoside; luteolin-7-*O*- β -D-galactoside; quercetin-3-*O*- β -D-glucoside; and hyperoside, were isolated from the plant (Gao et al. 1995). Six compounds, namely, corymbosin,

5-hydroxy-3',4',7-trimethoxyflavone, myristic acid, palmitic acid, sucrose and β -sitosterol, were isolated from the plant (Huang et al. 1996). Six triterpenoid saponins A–F were isolated from *Lonicera japonica* (Chen et al. 2000). The structure of a new triterpenoid saponin F was determined as 3-*O*- β -D-glucopyranosyl(1 \rightarrow 4)- β -D-glucopyranosyl(1 \rightarrow 3)- α -L-rhamnopyranosyl(1 \rightarrow 2)- α -L-arabinopyranosyl-hederagenin-28-*O*- β -D-glucopyranosyl(1 \rightarrow 6)- β -D-glucopyranosyl ester. Other known saponins were identified as hederagenin-3-*O*- α -L-rhamnopyranosyl (1 \rightarrow 2)- α -L-arabinopyranoside; 3-*O*- α -L-rhamnopyranosyl(1 \rightarrow 2)- α -L-arabinopyranosyl-hederagenin-28-*O*- β -D-xylopyranosyl(1 \rightarrow 6)- β -D-glucopyranosyl ester; 3-*O*- α -L-rhamnopyranosyl(1 \rightarrow 2)- α -L-arabinopyranosyl-hederagenin-28-*O*- β -D-glucopyranosyl(1 \rightarrow 6)- β -D-glucopyranosyl ester; 3-*O*- α -L-rhamnopyranosyl(1 \rightarrow 2)- α -L-arabinopyranosyl-hederagenin-28-*O*- α -L-rhamnopyranosyl(1 \rightarrow 2)[β -D-xylopyranosyl(1 \rightarrow 6)]- β -D-glucopyranosyl ester; and 3-*O*- β -D-glucopyranosyl(1 \rightarrow 3)- α -L-rhamnopyranosyl(1 \rightarrow 2)- α -L-arabinopyranosyl-hederagenin-28-*O*- β -D-glucopyranosyl(1 \rightarrow 6)- β -D-glucopyranosyl ester. Five iridoid glycosides, L-phenylalaninosecologanin, 7-*O*-(4- β -D-glucopyranosyloxy-3-methoxybenzoyl) secologanolic acid, 6'-*O*-(7 α -hydroxyswerosyloxy)loganin, and (*Z*)-aldosecologanin and (*E*)-aldosecologanin, were isolated from the stems and leaves of *Lonicera japonica* (Machida et al. 2002). Thirty-six constituents were isolated from the volatile oil of flowers and stems, among which 18 were common to both, accounting for 85.23 and 83.42 %, respectively (Li et al. 2002). Palmitic acid and linoleic acid predominated. A triterpenoid saponin, loniceroside C, was isolated from the aerial parts of *Lonicera japonica*, and its structure established to be 3-*O*- β -D-glucopyranosyl hederagenin 28-*O*- α -L-rhamnopyranosyl (1 \rightarrow 2)-[β -D-xylopyranosyl(1 \rightarrow 6)]- β -D-glucopyranosyl ester (Kwak et al. 2003). Hyperoside, chlorogenic acid, luteolin and caffeic acid were found to be the major important active ingredients of *L. japonica* crude herb (Peng et al. 2005). Seven compounds were isolated from *L. japonica*

extract and elucidated as luteolin, luteoloside, quercetin, quercetin-3-*O*- β -D-glucoside, quercetin-7-*O*- β -D-glucoside, rutin and chlorogenic acid (Chen et al. 2010b).

Secologanin synthase, an enzyme catalyzing the oxidative cleavage of the cyclopentane ring in loganin to form secologanin, was detected in microsomal preparations from cell suspension cultures of *Lonicera japonica* (Yamamoto et al. 2000). The activity of 7-deoxyloganin 7-hydroxylase, an enzyme catalyzing the conversion of 7-deoxyloganin into loganin, was detected in a microsomal preparation from the cell suspension cultures of *Lonicera japonica* (Katano et al. 2001). Two secoiridoid glucoside artefacts, 7-*O*-butylsecologanic acid and secologanin dibutylacetal, were isolated from a butanol extract of *Lonicera japonica*, along with loganin, sweroside and secologanin (Tomassini et al. 1995). The authors showed that acetalic iridoids could be easily formed by reaction of the aldehydic function with alcoholic solvents.

One hundred and thirteen compounds were separated from the volatile oil of *L. japonica* of which 89 representing 77.99 % of the oil were characterized (Yang et al. 2007). Constituents with relative content greater than 2 % were palmitic acid (6.05 %), menthol 5 %, L-linalool (3.95 %), caryophyllene oxide (3.49 %), 6,10,14-trimethyl-2-pentadecanone (3.47 %), 1-octanol (2.92 %), β -caryophyllene (2.70 %), camphor (2.59 %), borneol (2.40 %), β -selinene (2.37 %) and δ -cadinene (2.13 %). Remaining constituents included the following: 5-ter-butyl-1,3-cyclopentadiene (0.18 %), (*E*)-2-hexenal (0.117 %), *p*-xylene (0.042 %), 1-hexanol (0.104 %), heptanal (0.207 %), α -thujene (0.063 %), α -pinene (0.839 %), camphene (0.490 %), (*E*)-2-heptenal (0.089 %), benzaldehyde (0.696 %), β -pinene (0.618 %), 1-octan-3-ol (0.277 %), 2,3-octanedione (0.194 %), 6-methyl-5-hepten-2-one (0.368 %), 2-pentylfuran (1.015 %), 3-octanol (0.146 %), octanal (0.669 %), terpinolene (0.096 %), *p*-cymene (0.885 %), limonene (0.897 %), 1,8-cineole (1.229 %), *E*-3-octen-2-one (0.080 %), hyacinthine (0.187 %), γ -terpinene (0.484 %), artemisia

ketone (0.260 %), 1-menthone (0.530 %), isoborneol (0.522 %), *p*-menthone (0.204 %), 4-terpineol (1.612 %), α -terpineol (0.905 %), β -cyclocitral (0.255 %), bornyl formate (0.220 %), 3-methoxy-*p*-cymene (0.526 %), pulegone (0.526 %), carvacrol methyl ether (0.577 %), piperitone (0.733 %), cinnamal (0.248 %), durenol (0.349 %), bornyl acetate 0.330 %, *E*-anethole (0.803 %), thymol (1.301 %), carvacrol (1.106 %), junipene (0.167 %), α -cubebene (0.131 %), eugenol (0.532 %), α -copaene (0.483 %), β -elemene (0.501 %), tetradecane (0.509 %), isolongifolene (0.486 %), methyl eugenol (0.378 %), 3-ter-butyl-1,2-dimethoxybenzene (1.352 %), 1,3,-diisopropenyl-6-methylcyclohexene (1.695 %), 4-ter-butyl-catechol (0.625 %), geranyl acetone (1.878 %), β -bisabolene (0.789 %), aromadendrene (0.468 %), AR-curcumene (1.243 %), pentadecane (1.454 %), α -muurolene (0.547 %), α -bisabolene (0.924 %), γ -cadinene (0.495 %), coniferol (1.167 %), motrin methyl ester (0.4 %), spathulenol (0.78 %), hexadecane (0.94 %), α -cedrol (0.47 %), τ -muurolol (0.735 %), α -cadinol (1.388 %), heptadecane (0.729 %), hexadecanal (0.526 %), 3 N-butylphthalide (0.524 %), myristic acid (1.311 %), octadecan (0.293 %), neophytadiene (0.546 %), pentadecanoic acid (0.465 %), nonadecane (0.239 %), farnesyl acetone (0.917 %), methyl palmitate (0.270 %), sandaracopimaradiene (0.296 %), eicosane (0.463 %), heneicosane (0.403 %), phytol (1.771 %), oleic acid (0.830 %), stearic acid (0.377 %), docosane (0.356 %), tricosane (0.474 %), tetracosane (0.333 %), pentacosane (0.534 %), hexacosane (0.240 %), heptacosane (0.274 %), octacosane (0.170 %) and nonacosane (0.250 %).

A total of 89 compounds were identified in the essential oils from the flower, leaf and stems of *L. japonica* (Vukovic et al. 2012). The main constituents were (*Z,Z*)-farnesol (16.2 %) and linalool (11.0 %) for the flower fraction, hexadecanoic acid (16.0 %) and linalool (8.7 %) for the leaf fraction and hexadecanoic acid (31.4 %) for the stem. Monoterpene hydrocarbons were absent from all the oils, and oxygenated sesquiterpenes were not identified in the essential oil of the stem.

Fruit Phytochemicals

The following carotenes were identified in *L. japonica* berries: phytofluene, β -carotene, ζ -carotene, lycopene, γ -carotene, η -carotene and xanthophylls, cryptoxanthin, zeaxanthin and auroxanthin (Goodwin 1952). The xanthophylls existed almost exclusively as esters and cryptoxanthin were the major components.

An unusual carotenoid, η -carotene (7,8,7',8'-tetrahydro- β , β -carotene), a natural C(40) carotenoid, first detected in the berries of *Lonicera japonica* was synthesized by olefin cross-metathesis/dimerization of a C(21) polyene derived from *trans*-7,8-dihydroretinal (Fontán et al. 2012).

Leaf Phytochemicals

Two biflavonoids 3'-*O*-methyl loniflavone [5,5'',7,7''-tetrahydroxy 3'-methoxy 4',4'''-biflavonyl ether] and loniflavone [5,5'',7,7'',3'-pentahydroxy 4',4'''-biflavonyl ether] along with luteolin and chrysin were isolated from the leaves of *Lonicera japonica* (Kumar et al. 2005). The leaves were found to be a source strictosidine, a key intermediate in the biosynthesis of the terpenoid indole alkaloid (T1A) pathway (Nam et al. 2007). Three monocaffeoylquinic acids (3-CQA, 4-CQA, 5-CQA) and 5-feruloylquinic acid (5-FQA) were detected in the leaves (Wang and Clifford 2008). Five caffeoylquinic acid derivatives were isolated from the leaves, and their structures were identified as 3,4-di-*O*-caffeoylquinic acid methyl ester; 5-*O*-caffeoylquinic acid methyl ester; 3,4-di-*O*-caffeoylquinic acid; 1,3-di-*O*-caffeoylquinic acid; and chlorogenic acid (Ma et al. 2009). The levels of rutin, luteoloside, isochlorogenic acid, chlorogenic acid and caffeic acid were determined in new leaves of *L. japonica* (Niu et al. 2012). The contents of chlorogenic acid and caffeic acid in *Lonicera* new leaves were 2.572 and 1.498 %, respectively, both higher than those cited in Chinese Pharmacopoeia.

Stem Phytochemicals

Seven major components, namely, chlorogenic acid, caffeic acid, loganin, sweroside, secoxyloganin, rutin and luteolin 7-*O*-glucoside, were found in the stem (Qian et al. 2007a). Thirteen compounds were isolated and identified from the stems: protocathechuic acid, caffeic acid, macranthoin G, esculetin, luteolin, quercetin, apigenin, luteolin-7-*O*- β -D-glucopyranoside, isorhamnetin-7-*O*- β -D-glucopyranoside, diosmetin-7-*O*- β -D-glucopyranoside, rhoifolin, lonicerin and hydnocarpin D (Zhang et al. 2009). The biflavones 7,7''-dimethylanarafflavone, agathisflavone and 7''-methylagathisflavone were isolated from *L. japonica* stems (Pradhan et al. 2009).

Twelve compounds were isolated from the 70 % ethanol extract of the stem, and their structures were identified as six triterpenoids (24S)-cycloart-25-en-3 β ,24-diol, pomolic acid, ursolic acid, euscaphic acid, hederagenin and 23-hydroxytormentic acid and six sterols obtusifoliol, gramisterol, citrostadienol, β -sitosterol, ergosterol peroxide and β -sitosterol glucoside (Kim et al. 2009a). Six iridoids were isolated from the 70 % ethanol extract of the stem and their structures identified as epialyxialactone, secologanin dimethyl acetal, sweroside, loganin, loganic acid and demethylsecologanol (Kim et al. 2009b). Fourteen compounds were isolated from the 70 % ethanol extract of the stem, and their structures were elucidated as seven aliphatic compounds long-chain alcohols (1, 2), trilinolein (3), hexacosanol (4), fatty acids (6), 9,12,13-trihydroxyoctadeca-10(E),15(Z)-dienoic acid (10) and pinellic acid (11) and seven phenolics bis(2-ethylhexyl) phthalate (dioctylphthalate, DOP) (5), coniferaldehyde (7), caffeic acid docosanoyl ester (8), caffeic acid (9), coniferyl aldehyde 4-*O*-glucoside (12), linarin (13) and coniferin (14) (Kim et al. 2009c). A new 2,7'-cyclolignan named lonicerinol and eight known lignans, (–)-epipinoresinol, (–)-pinoresinol, 9 α -hydroxypinoresinol, 7R,8S-dihydrodehydrodiconiferyl alcohol, (\pm)-neo-olivil, (+)-isolariciresinol, 3-methoxy-8,4'-oxyneoligna-3',4,7,9,9'-pentol and (–)-pinoresinol 4-*O*-glucoside, were isolated from the stem (Yean et al. 2010).

Lonicera japonica was reported to contain more than 140 compounds comprising essential oils, organic acids and flavones (Shang et al. 2011), flavonoids, iridoid glucosides, saponins and phenolic acids (Chen et al. 2007a, b) and its active principles to possess wide pharmacological actions, such as antiinflammatory, antibacterial, antiviral, antioxidative and hepatoprotective activities (Shang et al. 2011). Some of the pharmacological properties of the various plant parts are discussed below.

Antioxidant Activity

Among the methanol extract and the dichloromethane, ethyl acetate, n-butanol and water fractions, the ethyl acetate fraction of *Lonicera japonica* flowers exhibited marked scavenging/inhibitory activities, as follows: IC₅₀ values of 4.37, 27.58 and 12.13 μ g/mL in the DPPH, total ROS, ONOO- and *OH assays, respectively (Choi et al. 2007). A new triterpenoid glycoside, oleanolic acid 28-*O*- α -L-rhamnopyranosyl-(1 \rightarrow 2)-[β -D-xylopyranosyl(1 \rightarrow 6)]- β -D-glucopyranosyl ester (12), and 11 known compounds, including chrysoeriol (1), luteolin (2), 5-hydroxymethyl-2-furfural (3), caffeic acid (4), protocathechuic acid (5), chrysoeriol 7-*O*- β -D-glucopyranoside (6), isorhamnetin 3-*O*- β -D-glucopyranoside (7), kaempferol 3-*O*- β -D-glucopyranoside (8), quercetin 3-*O*- β -D-glucopyranoside (9), hederagenin 3-*O*- α -L-arabinopyranoside (10) and luteolin 7-*O*- β -D-glucopyranoside (11), were isolated from the ethyl acetate fraction. Compounds 2, 4, 5, 7, 9 and 11 exhibited marked scavenging activities, with IC₅₀ values of 2.08–11.76 μ M for 1,1-diphenyl-2-picrylhydrazyl (DPPH) radicals and 1.47–6.98 μ M for ONOO-.

Fourteen compounds, namely, chlorogenic acid, 1-*O*-caffeoylquinic acid (1-*O*-CQA), caffeic acid, 4-*O*-CQA, rutin, isoquercitrin, luteolin-7-*O*-glucoside, lonicerin, 4,5-*O*-dicaffeoylquinic acid (4,5-*O*-diCQA), 3,5-*O*-diCQA, 1,3-*O*-diCQA, 3,4-*O*-diCQA, 1,4-*O*-diCQA and luteolin, were isolated from *L. japonica* flower buds by HPLC-DAD-TOF/MS and found to have antioxidant activity as assayed by DPPH (Tang et al. 2008).

The ethanol extracts of various aerial parts were found to be highly enriched in the total phenolic contents as gallic acid equivalents and in the antioxidant capacity as γ -ascorbic acid equivalents (Dung et al. 2011). The extracts exhibited potent DPPH and superoxide radical scavenging activities, which were found to be stronger than butylated hydroxyanisole and slightly weaker than ascorbic and gallic acids. The IC_{50} values of DPPH and superoxide radical scavenging capacities of the extracts ranged between 19.45–57.97 and 16.60–38.63 μ g/ml.

Antiinflammatory Activity

The *n*-butanol fraction of *Lonicera japonica* showed antiinflammatory activity in mice and rats (Lee et al. 1994). Several constituents such as loniceriside A and B, flavonoids and iridoids were isolated from this fraction. Loniceriside A, hederagenin, lonicerin and loganin, major constituents of *L. japonica* flower *n*-butanol fraction, showed antiinflammatory activity comparable to aspirin in the croton oil-induced ear oedema and adjuvant-induced arthritis models in mice (Lee et al. 1995a, b). Lonicerin was not tested in the adjuvant-induced arthritis model.

At oral doses of 100–400 mg/kg, the *n*-butanol fraction of *L. japonica* showed antiinflammatory activity against acute, granulomatic and chronic inflammation models in mice and rats (Lee et al. 1998). Although the activity was not potent compared with prednisolone, the results supported the traditional use and suggested that this fraction of *L. japonica* may yield a safe and mild antiinflammatory agent for treating various inflammatory disorders.

The aqueous extract from *Lonicera japonica* flower exhibited antiinflammatory effects in lipopolysaccharide (LPS)-induced rat liver sepsis (Lee et al. 2001). The extract inhibited the increase of nuclear factor (NF)- κ Bp65 and degradation of I- κ B α in the liver of LPS-challenged rats. Immunohistochemical analysis of rat hepatocytes showed that LPS-induced inflammatory responses, involving degradation of I- κ B α and induction of

NF- κ Bp65, tumour necrosis factor (TNF)- α and inducible nitric oxide synthase (iNOS), were partially inhibited by pretreatment with the extract. The results suggested that the extract may act as a therapeutic agent for inflammatory disease through a selective regulation of NF- κ B activation. Loniceriside C isolated from the aerial parts showed in-vivo antiinflammatory activity against mouse ear oedema provoked by croton oil (Kwak et al. 2003). At doses of 50, 100 and 200 mg/kg, *L. japonica* aqueous extract exhibited significant inhibition of both change in paw thickness and vascular permeability in proteinase-activated receptor 2 (PAR2)-mediated mouse paw oedema (Tae et al. 2003). The extract (100 mg/kg) also significantly inhibited PAR2 agonist-induced myeloperoxidase (MPO) activity and tumour necrosis factor (TNF)- α expression in paw tissue. An aqueous extract of *L. japonica* demonstrated potent inhibition of the production of the proinflammatory mediators, nitric oxide (NO) and tumour necrosis factor α (TNF- α) in a dose-dependent manner in an activated macrophage-like cell line, RAW 264.7 cells (Park et al. 2005). Aqueous fraction of *L. japonica* (10, 100 and 1,000 μ g/ml) dose dependently inhibited TNF- α secretion (Kang et al. 2004). The extract at similar doses also inhibited TNF- α and tryptase mRNA expression in trypsin-stimulated human mast cell -1. Further, the extract inhibited trypsin-induced ERK phosphorylation. The results indicated that *L. japonica* may inhibit trypsin-induced mast cell activation through the inhibition of ERK phosphorylation than the inhibition of trypsin activity.

Ochnaflavone, isolated from *Lonicera japonica*, was found to dose dependently inhibit cyclooxygenase-2 (COX-2)-dependent phases of prostaglandin D₂ (PGD₂) generation in bone marrow-derived mast cells (BMMC) with IC_{50} values of 0.6 μ M (Son et al. 2006). The decrease in quantity of the PGD₂ product was accompanied by a decrease in the COX-2 protein level. Additionally, ochnaflavone consistently and dose dependently inhibited the production of leukotriene C₄ (LTC₄), with an IC_{50} value of 6.56 μ M and degranulation reaction, with an IC_{50} value of

3.01 μM . The results demonstrated that ochnaflavone had a dual cyclooxygenase-2/5-lipoxygenase inhibitory activity and might provide a basis for novel antiinflammatory drugs. In another study, ochnaflavone (isolated from *Lonicera japonica*) treatment dose-dependently inhibited the production of nitric oxide and also blocked the lipopolysaccharide (LPS)-induced expression of iNOS lipopolysaccharide in RAW264.7 cells (Suh et al. 2006a). The inhibition of LPS-induced NO formation by ochnaflavone was mediated by ERK1/2 via NF-kappaB inhibition, which may be the mechanistic basis for the antiinflammatory effects of ochnaflavone. Boiled aqueous honeysuckle flower extracts directly inhibited both COX-1 and COX-2 activity, while non-boiled extracts stimulated COX-1 (Xu et al. 2007). Boiled extracts also inhibited expression of IL-1beta-induced COX-2 protein expression and suppressed its mRNA induction by IL-1beta in A549 cells. The findings suggested that direct inhibition of COX isoenzymes as well as downregulation of COX-2 mRNA and protein may represent the mechanism by which honeysuckle flower treatment decreased inflammation.

Luteolin, a major flavonoid of *Lonicera japonica*, was found to suppress TNF-alpha-induced IL-8 production in dose-dependent manner in human colonic epithelial cells HT29 cells (Kim et al. 2005). Further, luteolin inhibited TNF-alpha-induced phosphorylation of p38 MAPK and extracellular-regulated kinases (ERK), IkappaB degradation and NF-kappaB activation. The results suggested that luteolin elicited inhibitory effects on TNF-alpha-induced IL-8 production in the intestinal epithelial cells through blockade in the phosphorylation of MAPKs, following IkappaB degradation and NF-kappaB activation. Of 13 phenolic compounds isolated from the flower bud, only luteolin showed significant inhibitory activity against 5-lipoxygenase-catalyzed leukotriene production (Lee et al. 2010a). Luteolin, flavonoid from honeysuckle flowers, significantly inhibited the induction of inflammatory cytokines such as tumour necrosis factor (TNF)-alpha, interleukin (IL)-8, IL-6 and granulocyte-macrophage

colony-stimulating factor (GM-CSF) induced by phorbol 12-myristate 13-acetate (PMA) plus A23187-induced mast cell activation (Kang et al. 2010b). Additionally, luteolin attenuated cyclooxygenase (COX)-2 expression and intracellular Ca^{2+} levels. In activated HMC-1 (human mast cell) cells, the phosphorylation of extracellular signal response kinase (ERK 1/2) and c-jun N-terminal kinase (JNK 1/2), but not p38 mitogen-activated protein kinase (p38 MAPK), were decreased by treatment of the cells with luteolin. Luteolin inhibited PMA plus A23187-induced nuclear factor (NF)-kappaB activation, IkappaB degradation and luciferase activity and suppressed the expression of TNF-alpha, IL-8, IL-6, GM-CSF and COX-2 through a decrease in the intracellular Ca^{2+} levels. Luteolin also suppressed ERK 1/2, JNK 1/2 and NF-kappaB activation. The results indicated that luteolin from honeysuckle flowers exerted a regulatory effect on mast cell-mediated inflammatory diseases, such as rheumatoid arthritis, allergy disease and inflammatory bowel disease.

The removal of tannin and saponin from *L. japonica* extract resulted in loganin- and sweroside-enriched *L. japonica* extract that showed reduced haemolysis and protein precipitation (Ryu et al. 2010). In efficacy tests, the enriched extract inhibited croton oil- and arachidonic acid-induced ear oedema, acetic acid-induced writhing and carrageenan-induced rat hind-paw hyperalgesia. Inhibition of cyclooxygenase-2, inducible nitric oxide synthase and 5-lipoxygenase activities by the enriched tannin- and saponin-free extract appeared to be the mechanism underlying antiinflammatory and analgesic efficacy. Loganin and sweroside also showed antiinflammatory and analgesic activities, suggesting that they might be active principles in the efficacy of the enriched extract.

Lonicera japonica fermented with *Lactobacillus casei* was found to exert a protective effect against lipopolysaccharide (LPS) induced lung inflammation into Balb/c mice (Lee et al. 2011b). In mice treated with the fermented extract, neutrophil influx, total neutrophil number, TNF- α and IL-6 levels in BAL fluid were significantly reduced compared to the LPS group.

The data suggested that fermented *L. japonica* may afford a novel therapeutic agent for lung inflammation and in particular for chronic obstructive pulmonary disease. Administration of water extract of *L. japonica* flowers to mice with dextran sulphate sodium-induced colitis elicited dose-dependent inhibitory effects against colon shortening, weight loss and histological damage (Park et al. 2012c). The extract downregulated interleukin IL-1 β , tumour necrosis factor alpha (TNF- α), interferon- γ , IL-6, IL-12 and IL-17. However, the extract did not show any significant effects on IL-10, IL-23, transforming growth factor- β 1 and regulatory T (Treg) cell populations. The authors concluded that *L. japonica* flower extract showed protective effects against dextran sulphate sodium-induced colitis via the helper T (Th1/Th17) pathway and not via Treg cell-related mechanisms. Studies showed that that polyphenol components isolated from Korea *L. japonica* exhibited antiinflammatory effect on lipopolysaccharide (LPS)-stimulated RAW 264.7 cells through the decrease of proinflammatory mediators tumour necrosis factor alpha, interleukin- (IL-) 1 β and IL-6 expression by suppressing NF- κ B and p38 MAPK activity (Park et al. 2012b).

WIN-34B, an herbal formula comprising *Lonicera japonica* dried flowers and *Anemarrhena asphodeloides* dried roots, exhibited better antiinflammatory activity than that of celecoxib in carrageenan-induced paw oedema at the dose of 200 mg/kg and croton oil-induced paw oedema and ear oedema at the doses of 200 and 400 mg/kg (Kang et al. 2010a). WIN-34B exhibited significant antiinflammatory effects on vascular permeability. WIN-34B also exhibited significant antinociceptive activities in the late phase of formalin-induced paw licking and writhing response model in mice. In radiant heat tail-flick and carrageenan-induced paw pressure tests, WIN-34B at the dose of 400 mg/kg and at the doses of 200 and 400 mg/kg presented similar activities to indomethacin and celecoxib. Compared to indomethacin, WIN-34B at 400 mg/kg showed similar or better antinociceptive activities after 1 and 2 hours of therapy in the hot-plate test and better antinociceptive activity than that

of celecoxib in Hargreaves test. In the MIA-induced osteoarthritis animal models, WIN-34B at 400 mg/kg exhibited similar or better antinociceptive property than that of celecoxib throughout the pain measurement periods. In another study, WIN-34B, an herbal medicine of *L. japonica* dried flowers and *Anemarrhena asphodeloides* dried roots, significantly inhibited the IL-1 β -induced cell viability in human osteoarthritis fibroblast-like synoviocytes without cytotoxicity (Huh et al. 2012). Compared to celecoxib, WIN-34B exhibited similar or better antiinflammatory effects through significant suppression of inflammatory mediators (IL-1 β , TNF- α , PGE2 and NO), MMPs (MMP-1, MMP-3 and MMP-13) and aggrecanases (ADAMTS-4 and ADAMTS-5) and enhancement of TIMPs (TIMP-1 and TIMP-3). Moreover, WIN-34B reduced the phosphorylation of I κ B- α , ERK1/2, p38 and JNK1/2 in IL-1 β -stimulated human osteoarthritis fibroblast-like synoviocytes.

Pleuroprotective Activity

Pretreatment of Balb/c mice with *L. japonica* flower extract was found to have a protective effects against lipopolysaccharide (LPS)-induced lung inflammation which resembled a chronic obstructive pulmonary disease (Lee et al. 2011a). At 3 days after LPS stimulation, in-vivo study demonstrated that the influx of neutrophils and total cells were decreased significantly in *Lonicera* pretreated group compared to LPS only treated group. In addition, TNF- α and IL-6 levels in bronchoalveolar lavage (BAL) fluid were decreased in *Lonicera* pretreated group. The histological results demonstrated that *Lonicera* attenuated the LPS-induced lung inflammation and the expression of neutrophil elastase was decreased in *Lonicera* pretreated group.

Luteolin, the major polyphenolic component of *Lonicera japonica*, was found to have beneficial effects against lipopolysaccharide (LPS)-induced acute lung injury in mice (Lee et al. 2010b). The attenuation of neutrophil chemotaxis and respiratory burst by luteolin involved inhibition of MAPK/ERK kinase 1/2 (MEK),

extracellular signal-regulated kinase (ERK) and Akt phosphorylation signalling cascades. Another study showed luteolin, an active flavonoid compound isolated from *Lonicera japonica*, had potent antifibrotic activity; this effect was mediated, at least in part, by inhibition of lung inflammation as evidenced by suppression of neutrophil infiltration as well as TNF- α and interleukin IL-6 elevation in the bronchoalveolar lavage fluid in bleomycin-instilled C57BL/6J mice and suppression of TGF- β 1-induced α -SMA, type I collagen and vimentin expression in primary cultured mouse lung fibroblasts as well as epithelial to mesenchymal transition (Chen et al. 2010a).

Gastroprotective Activity

The dried flowers of *Lonicera japonica* and the dried root of *Anemarrhena asphodeloides*, component herbs of WIN-34B, are traditionally used in eastern medicine to treat various inflammatory conditions including arthritis (Huh et al. 2011). Their studies showed that WIN-34B did not cause acute or chronic toxicity in male or female rats. In addition, WIN-34B did not cause significant gastric mucosal damage, instead appearing to protect the mucosa from diclofenac-induced gastric damage by reducing the production of prostaglandin E(2) and leukotriene B(4).

Antiangiogenic, Antinociceptive Activity

The ethanol flower extract of *L. japonica* dose-dependently inhibited chick chorioallantoic membrane angiogenesis (Yoo et al. 2008). The antinociceptive activity of the extract was determined using the acetic acid-induced constriction model in mice. The extract showed antiinflammatory activity in two in-vivo models: the vascular permeability and air pouch models. The extract suppressed the production of nitric oxide via downregulation of inducible nitric oxide synthase in lipopolysaccharide-stimulated RAW264.7 macrophage cells. The results showed

that the flowers of *L. japonica* possessed potent antiangiogenic and antinociceptive activities, in addition to antiinflammatory activity.

Anticancer Activity

The floral absolute volatiles of the flowers showed appreciable cytotoxic activity on the brain cancer cell line U251 (IC₅₀ value of 7.92 μ g/ml) and were found to be more potent than cisplatin reference drug (IC₅₀=8.66 μ g/ml) (El-Kashoury et al. 2007). Meanwhile, the flower volatiles prepared by hydrodistillation/hexane extraction showed notable cytotoxic activity on the liver cancer cell line HepG2 with IC₅₀ value of 7.58 μ g/ml.

Protocatechuic acid, chlorogenic acid and luteolin from *Lonicera japonica* effectively killed the HepG2 hepatocellular carcinoma cells at 100 μ mol/L (Yip et al. 2006). Among these three naturally occurring phenolic compounds, only protocatechuic acid was capable of stimulating the c-Jun N-terminal kinase (JNK) and p38 subgroups of the mitogen-activated protein kinase (MAPK) family. In addition, the aqueous extract of *Lonicera japonica* also triggered HepG2 cell death in a JNK-dependent manner, but the amount of protocatechuic acid alone in this herbal extract was insufficient to contribute to the subsequent cytotoxic effect.

Luteolin (3',4',5,7-tetrahydroxyflavone), active compound from *L. japonica*, was found to induce human lung carcinoma CH27 cell apoptosis by caspase-dependent and caspase-independent pathway, and the effect of luteolin on apoptosis of CH27 cells was associated with DNA damage and the expression of DNA repair enzyme (Leung et al. 2005). They found that luteolin-induced CH27 cell apoptosis was accompanied by activation of antioxidant enzymes, such as superoxide dismutase and catalase, but not through the production of reactive oxygen species and disruption of mitochondrial membrane potential (Leung et al. 2006). Therefore, the effects of luteolin on CH27 cell apoptosis were suspected to result from the antioxidant rather than the prooxidant action of luteolin. Leung et al. (2008) also showed

that photodynamic therapy with alcohol extract from *Lonicera japonica* as photosensitizer exhibited significant photocytotoxicity in lung CH27 carcinoma cells at a concentration range of 50–150 $\mu\text{g/ml}$, with 0.4–1.2 J/cm^2 light dose. This action was found to be mediated via P38-associated pathway. They found that photodynamic therapy with *L. japonica* extract-induced CH27 cells apoptosis was probably related to its ability to change the protein expression and distribution of heat shock protein 27.

The biflavones isolated from *L. japonica* stems exhibited in-vitro anticancer activity (Pradhan et al. 2009). The results show significant activities, particularly for 7,7''-dimethylanaraflavone (IC_{50} values of 1.77, 3.42 and 3.59 mg/ml for NCI-H460, non-small cell lung carcinoma; MCF-7 breast; and OVCAR-3, ovarian adenocarcinoma cells, respectively), but low activity against HT-29 colon adenocarcinoma and RXF-393 renal cell carcinoma. In contrast, 7''-methylagathisflavone showed good inhibitory against all five cancer cell lines with IC_{50} values of 4 mg/ml . Polyphenolic extract from *L. japonica* dose-dependently inhibited hepatocarcinoma HepG2 cell proliferation at 48 hours (Park et al. 2012a). The polyphenolic extract affected HepG2 cell viability by inhibiting cell-cycle progression at the G2/M transition and inducing apoptosis. The extract also decreased the expression of CDK1, CDC25C, cyclin B1, pro-caspases-3 and pro-caspases-9 and poly (ADP-ribose) polymerase and affected the levels of mitochondrial apoptotic-related proteins. The results indicated that inhibition of PI3K/Akt and activation of MAPKs were pivotal in G2/M cell-cycle arrest and apoptosis of human hepatocarcinoma cells mediated by the polyphenolic extract.

Antiplatelet Aggregation Activity

Polyphenolic compounds isolated from *Lonicera japonica*, namely, methyl caffeate, 3,4-di-*O*-caffeoylquinic acid and methyl 3,4-di-*O*-caffeoylquinic acid, exhibited potent inhibitory effect on human platelet aggregation (Chang and Hsu 1992). They significantly inhibited the second

wave of platelet aggregation induced by ADP. Regarding thromboxane biosynthesis triggered by calcium ionophore A23187 in platelets, methyl caffeate and methyl 3,4-di-*O*-caffeoylquinic acid elicited the most potent inhibitory effect. Methyl 3,4-di-*O*-caffeoylquinic acid directly inhibited the conversion of arachidonic acid to thromboxane by platelet microsomes, while methyl caffeate did not have any significant effect on thromboxane biosynthesis in platelet microsomes. In the prevention of hydrogen peroxide-induced endothelial cell injury in culture, protocatechuic acid, methyl caffeate, methyl chlorogenic acid and luteolin were significantly effective. The inhibitory effect on platelet activation and the cytoprotective effect on hydrogen peroxide-induced cell injury may explain the possible role of polyphenolic compounds isolated from *L. japonica* in maintaining vascular homeostasis. Ochnaflavone, isolated from *Lonicera japonica*, strongly and non-competitively inhibited rat platelet phospholipase A2 (IC_{50} about 3 μM) (Chang et al. 1994). Inactivation was concentration and pH dependent (maximum inactivation occurred between pH 9.0 and 10.0). The inhibitory activity of ochnaflavone was rather specific against group II phospholipase A2 than group I phospholipase A2 (IC_{50} about 20 μM).

Lonijaposide C, a pyridinium alkaloid-coupled secoiridoid from the flower bud, exhibited activity against the release of glucuronidase in rat polymorphonuclear leukocytes induced by the platelet-activating factor (Song et al. 2008). Loniphenyruviridosides A–D, homosecoiridoids from *L. japonica* flower buds, inhibited STAT-3 (signal transducer and activator of transcription-3) activity of HELF (human embryonic lung fibroblasts) cells, while lonijaposides F, H, I and K showed activity against the release of glucuronidase in rat polymorphonuclear leukocytes induced by platelet-activating factor (Yu et al. 2011).

Antipyretic Activity

Studies showed that intravenous injection of *Lonicera japonica* extract elicited antipyretic effects on interleukin-1 β (IL-1 β)-induced thermogenesis

in febrile rabbits and acted by inhibiting expression of E-type prostaglandin receptor-3 (EP3) mRNA in the preoptic anterior hypothalamus of rabbits (Dong et al. 2008).

Immunomodulatory Activity

L. japonica flower was one of 26 Chinese medicinal herbs that was found active in promoting blood neutrophil activity and increasing neutrophil phagocytosis by over 35 % (Hu et al. 1992).

Haemolytic Activity

Among the 12 saponins isolated from the aerial parts, monodesmosides 1–4 showed strong haemolytic activity, but bisdesmosides 5–12 showed weak haemolytic activity; saponin 5 and 6 with an arabinosyl moiety at C-3 and a gentiobiosyl moiety at C-28 showed no haemolytic activity (Kawai et al. 1988b).

Hepatoprotective Activity

Several iridoid glycosides, loganin, 7-epi-loganin and secoxyloganin, isolated from honeysuckle flower buds were found to possess hepatoprotective activity (Li and Li 2005). Sweroside, an active ingredient of iridoid glycoside isolated *Lonicera japonica* flower buds, was reported to have strong hepatoprotective effect (Luo et al. 2009). After intravenous administration of sweroside, the percentage of accumulation of free form sweroside in bile duct was 31.2 % of the total dosage. The oral bioavailabilities of sweroside and the active ingredients of purified herbal extracts (IGEs-1) was estimated to F(sweroside) 0.31 % and F(IGEs-1) 0.67 %. The majority of sweroside excreted to faeces revealed one reason of the low oral bioavailability. The much higher value of F(IGEs-1) much higher than that of F(sweroside) revealed that ingredients in IGEs-1 such as loganin, secoxyloganin and some phenolic acids may promote the absorption of sweroside. Metabonomics studies by Sun et al. (2010) showed that *L. japonica* extract had a protective

effect in acute liver injury induced by dimethylnitrosamine in male Wistar rats.

Antiatherogenic Activity

Ochnaflavone, isolated from *L. japonica*, was found to inhibit dose-dependently tumour necrosis factor (TNF)-alpha-induced matrix metalloproteinase-9 (MMP-9) gene expression in human aortic smooth muscle cells (HASMC) (Suh et al. 2006b). These inhibitory effects were associated with reduced extracellular signal-regulated kinase 1/2 (ERK1/2) activity and G1 cell-cycle arrest. These findings indicated the efficacy of ochnaflavone in inhibiting cell proliferation, G1- to S-phase cell-cycle progress and MMP-9 expression through the transcription factors NF-kappaB and AP-1 on TNF-alpha-induced HASMC and thus elucidating the mechanism of the antiatherogenic activity of ochnaflavone.

Antiallergic Activity

The ethanol extract (35 %) of *L. japonica* buds was found to have allergy-preventive activity (Oku et al. 2011). Bioassay-guided fractionation of the 35 % EtOH extract led to isolation of chlorogenic acid (1) and three known iridoid derivatives, loganin (2), secoxyloganin (3) and sweroside (4), all of which inhibited the blood flow decrease in the tail vein of mice subjected to sensitization with hen egg-white lysozyme. The structure–activity relationship of iridoid derivatives, morroniside (5), geniposide (6), asperuloside (7), aucubin (8) and catalpol (9), was also tested using the same bioassay method. Compounds 2–5 and 9 having the sp(3) atom at C-8 showed an allergy-preventive effect, while compounds 6, 7 and 8 having a double bond at C-7 and C-8 did not.

Antibacterial Activity

The essential oil from the flowers and ethanol leaf extracts revealed a remarkable antibacterial effect against *Listeria monocytogenes*, *Bacillus*

subtilis, *Bacillus cereus*, *Staphylococcus aureus*, *Salmonella enteritidis*, *Salmonella typhimurium*, *Enterobacter aerogenes* and *Escherichia coli*. However, no effect was observed for *Pseudomonas aeruginosa* and *E. coli* O157:H7 (Rahman and Kang 2009). Ethanol leaf extract and its chloroform subfraction showed higher antibacterial activity by minimum inhibitory concentrations than did hexane and ethyl acetate subfractions. The butanol extract of *Lonicera japonica* was compared to other antimicrobial agents cefoxitin, imipenem, clindamycin and metronidazole for activity in-vitro against 104 clinical isolates of anaerobic bacteria (Rhee and Lee 2011). *L. japonica* extract and imipenem were the most active against *Bacteroides fragilis*, *Bacteroides ovatus*, *Clostridium difficile*, *Clostridium perfringens*, *Propionibacterium acnes* and *Peptostreptococci*. The ethanol extract of *L. japonica* flowering aerial parts exhibited significant antimicrobial activity in-vitro against *Staphylococcus aureus*, *Staphylococcus epidermidis*, *Escherichia coli*, *Candida albicans* and *Candida tropicalis* (Chen et al. 2012).

Antiviral Activity

Tannins such as caffeoylquinates (CQs) isolated from *Lonicera japonica* were shown to have selective inhibitory effect on HIV-1 reverse transcriptase (Chang et al. 1995). Kang Er Xin-I (KEX-I) a Chinese herbal recipe consisting of *Lonicera japonica*, *Ophiopogon japonicus* and *Astragalus membranaceus* had been proven useful to treat viral myocarditis (Yan 1991). In a random, paired and crossover design, after being treated with KEX-I for 2 weeks, the 26 patients' chief cardiac functional indexes assessed with systolic time intervals (STI) improved markedly. KEX-I was found to inactivate directly the virus of Cocksackie B3, protect the heart cells in mice, prevent attack by Cocksackie B3 virus, promote the growth of internal interferon and increase the NK cell's function to regulate immunity in the experimental mice. Thirteen caffeoylquinic acids, caffeic acid and caffeic acid methyl ester isolated from honeysuckle flowers showed antiviral activities

against respiratory viruses (Ma et al. 2005). A novel cyclic peroxide, shuangkangsu, isolated from the buds showed significant antiviral activities against influenza virus in chicken embryo and respiratory syncytial virus in cells (Yu et al. 2008).

Lonicera japonica flower extracts were found to have anti-influenza virus activity (Shi and Guo 2010). The most active ingredients were from the petroleum and ethanol extract which were more effective with a lower EC₅₀ value than ribavirin. Twelve functional protein components were determined in the anti-influenza virus serum marker of *L. japonica* using proteomics technology (Zhang et al. 2011).

Tyrosinase Inhibition Activity

The methanol and acetone extracts from *L. japonica* showed an inhibition effect against tyrosinase, xanthine oxidase and nitrite scavenging ability (Byun et al. 2004a, b). Tyrosinase inhibition effect of *L. japonica* was higher in the irradiated sample than the nonirradiated, and the effect was increased by irradiation doses. The high inhibitory effect against xanthine oxidase was not changed by irradiation. Nitrite scavenging activity was the highest in *L. japonica* extract at pH 1.2. The ethanol extracts of various aerial parts exerted significant tyrosinase inhibitory activity with IC₅₀ values ranging from 11.16 to 17.18 µg/ml (Dung et al. 2011). The ethanol flower extract displayed the highest test activities as compared with the other extracts. The results indicated that *L. japonica* could be used as an active ingredient for antioxidant and natural skin-whitening agent in cosmetic products.

Neuroprotective Activity

Studies demonstrated that *Lonicera japonica* extract possessed potent neuroprotective activity in human SH-SY5Y neuroblastoma cells (Kwon et al. 2011). *L. japonica* extract elicited radical scavenging ability in 2-diphenyl-1-picrylhydrazyl (DPPH) and 2,2-azinobis-(3-ethyl-benzthiazo-

line-6-sulfonic acid) (ABTS) assays and inhibited H₂O₂-induced up- and downregulation of cleaved PARP, cleaved caspase-3, Bcl-2 and Bcl-xL. Furthermore, the extract significantly attenuated the H₂O₂-induced phosphorylation of Akt, JNK, p38 MAPK and ERK1/2. They also found that *L. japonica* extract significantly increased cell viability decrease, lactate dehydrogenase release (LDH), morphological changes, nuclear condensation, fragmentation and reactive oxygen species (ROS) production induced by 6-hydroxydopamine (6-OHDA) in human SH-SY5Y neuroblastoma cells (Kwon et al. 2012). The cytoprotection afforded by pretreatment with the extract was associated with increases of the glutathione (GSH) level, superoxide dismutase (SOD) activity and catalase (CAT) activity in 6-OHDA-induced SH-SY5Y cells. In addition, the extract strongly inhibited 6-OHDA-induced mitochondrial dysfunctions including reduction of mitochondria membrane potential (MMP) and activation of cleaved poly (ADP-ribose) polymerase (PARP), cleaved caspase-3, cleaved caspase-9, increased Bax, as well as decreased Bcl-2 and Bcl-xL. These findings suggested that the extract had a potent anti-parkinsonism; this effect was mediated, at least in part, by inhibition of neurotoxicity, apoptotic cascade events and oxidative stress via activation of MAPKs, PI3K/Akt and NF- κ B. The methanol extract of *L. japonica* flower significantly protected neuronal cells against glutamate-induced excitotoxicity via antioxidative activity by inhibiting the subsequent overproduction of nitric oxide, reactive oxygen species and peroxide to the level of control cells (Weon et al. 2011).

Cardioprotective Activity

Rutin, isolated from *L. japonica*, was found to reduce oxidative stress-mediated myocardial damage in-vitro model and in-vivo model, which might be useful in treatment of myocardial infarction (Jeong et al. 2009). Treatment with rutin decreased expression of both cleaved form of caspase-3 and increased Bcl-2/Bax ratio in H9c2 cells which were decreased by hydrogen peroxide.

Further, rutin improved ischaemia/reperfusion (IR)-induced myocardial contractile function and reduced infarct size. Rutin administration also inhibited apoptosis in myocardial tissues in I/R rats by increasing Bcl-2/Bax ratio and decreasing active caspase-3 expression.

Wound Healing Activity

The ointment formulation prepared with 10 % (w/w) flowering *L. japonica* ethanol extract exhibited potent wound healing capacity as evidenced by the wound contraction in the excision wound model (Chen et al. 2012). The contents of hydroxyproline and hexosamine also correlated with the observed healing pattern. These findings were supported by the histopathological characteristics of healed wound sections, as greater tissue regeneration, more fibroblasts and angiogenesis were observed in the 10 % (w/w) *L. japonica* ointment-treated group. The results also indicated that the extract possessed potent antiinflammatory activity, as it enhanced the production of antiinflammatory cytokines that suppress proinflammatory cytokine production.

Hypoglycaemic Activity

The ethyl acetate fraction of the methanol extract of *Lonicera japonica* flower inhibited porcine pancreatic alpha-amylase activity in a dose-dependent manner, with an IC₅₀ of 0.2 mg/ml. The ethyl acetate fraction also significantly inhibited both intestinal sucrase and isomaltase activities at a concentration of 0.5 mg/ml (Kwon et al. 2004).

Growth Hormone Induction Activity

Methanol extract of the flowers was found to increase induction of rat growth hormone to 732.65 % in the pituitary cell culture system (Jung et al. 2003). Ochnaflavone, a constituent from honeysuckle leaf, also increased growth hormone to 329.73 % in the pituitary cell culture system.

Toxicity/Safety Studies

Acute and subacute toxicity study of the ethanol leaf extract of *Lonicera japonica* at 5,000 mg/kg did not produce mortality or significant changes in the general behaviour and gross appearance of the internal organs of rats (Thanabhorn et al. 2006). There were no significant differences in the body and organ weights between the control and the treated group of both sexes. Haematological analysis and clinical blood chemistry revealed no toxicity effects of the extract. Pathologically, neither gross abnormalities nor histopathological changes were observed.

Challenge tests were performed according to the European Pharmacopoeia procedures and criteria for various cosmetic formulations containing antimicrobial extracts of *Lonicera caprifolium* and *Lonicera japonica* alone or in combination with glyceryl caprylate and/or levulinic acid, *p*-anisic acid and ethanol (Papageorgiou et al. 2010). Formulations such as shampoo, shower gel and conditioning cream fulfilled criterion A, while tonic lotion, anticellulite cream, cleansing milk and peeling cream fulfilled criterion B, in regard to contamination from *A. niger*. The addition of antimicrobial fragrance ingredients such (≤ 0.3 % w/w) levulinic acid or (0.1 % w/w) *p*-anisic acid and/or (5 % w/w) ethanol afforded products that met criterion A in challenge tests and were also microbiologically safe during use. The small quantity (5 % w/w) of ethanol afforded an important assistance in order to boost the self-preserving system and to produce stable and safe products.

Allergy Problem

A case of linear itchy raised blisters on the wrist of a patient that pulled Japanese honeysuckle (*Lonicera japonica*) was reported by Webster (1993).

Traditional Medicinal Uses

Lonicera japonica, a widely used traditional Chinese medicine, is taken to treat the exopatho-

genic wind-heat, epidemic febrile diseases, sores, carbuncles and some infectious diseases (Shang et al. 2011). Honeysuckle is used in Chinese medicine to address what are called excess heat conditions such as fevers, skin rashes and sore throat associated with inflammatory processes involving heat, redness, pain and swelling often due to external pathogenic factors such as bacteria and viruses (Yeung 1985). Also, according to traditional Chinese medicine, honeysuckle is contraindicated for patients with medical conditions that are diagnosed as deficient and cold in nature unless combined with other herbs to balance the cold temperature property of honeysuckle. The plant is also used to reduce blood pressure (Yeung 1985; Bown 1995). Honeysuckle dispels heat and detoxicates and is good for treating carbuncles, skin swelling, rheumatoid arthritis, hepatitis, scrofula, dysentery and haemorrhoids (Peng et al. 2000; Lu 2005). Dried flower buds of *Lonicera japonica* is one of the most widely used traditional Chinese medicines (TCMs) and recorded in China Pharmacopoeia with the Chinese name Jin Yin Hua for the treatment of acute fever, headache, pharyngodynia, respiratory infection, pyocutaneous disease and epidemic disease (Qian et al. 2008). In Malaysia, the Chinese import the flowers for use medicinally for their antifebrile and astringent properties (Burkill 1966). An infusion of the flower buds is used in the treatment of a wide range of ailments including syphilitic skin diseases, tumours, bacterial dysentery, colds, enteritis, pain and swellings (Yeung 1985; Duke and Ayensu 1985; Foster and Duke 1998; Bown 1995). Honeysuckle flower buds and stems are alterative, antibacterial, antiinflammatory, antispasmodic, depurative, diuretic and febrifuge (Yeung 1985; Bown 1995). Externally, the flowers are applied as a wash to skin inflammations, infectious rashes and sores, and the stems are used internally in the treatment of acute rheumatoid arthritis, mumps and hepatitis (Bown 1995). *Lonicera japonica* and *Anemarrhena asphodeloides* components of an herbal formula WIN-34B have been used for the treatment of a variety of inflammatory diseases, arthritis, cold

and infective diseases in many countries, including Korea and China (Kang et al. 2010a; Huh et al. 2011).

Other Uses

A very vigorous climbing plant, it makes a good dense ornamental ground cover plant. In both its native and introduced range, Japanese honeysuckle can be a significant source of food for deer, rabbits, hummingbirds and other wildlife. The bark is tough and can be used for plaiting.

The essential oil from the flower buds has insecticidal property and was found to be toxic to storage insects. The essential oil exhibited strong contact toxicity against maize weevil *Sitophilus zeamais* and book louse *Liposcelis bostrychophila* with LD₅₀ values of 21.54 µg/adult and 64.04 µg/cm², respectively (Zhou et al. 2012). The constituent compounds, estragole (LD₅₀=49.95 µg/cm²) and linalool (LC₅₀=172.54 µg/cm²), also possessed contact toxicity against *L. bostrychophila*. *L. japonica* essential oil and its constituent compounds (estragole and linalool) exhibited fumigant toxicity against *S. zeamais* with LC₅₀ values of 13.36, 14.10 and 10.46 mg/L, respectively. The essential oil of *L. japonica* (LC₅₀=0.20 mg/L) and its constituent compounds, estragole (LC₅₀=0.16 mg/L) and linalool (LC₅₀=0.41 mg/L), also elicited fumigant toxicity against *L. bostrychophila*.

Comments

In the United States, Japanese honeysuckle is classified as a noxious weed in Texas, Illinois and Virginia and is banned in New Hampshire (Miller 2003). It is listed on the New Zealand National Pest Plant Accord as an unwanted organism (NBII and ISSG 2005). It is regarded as an environmental weed in Queensland, New South Wales, the ACT, Victoria, Tasmania, South Australia and Western Australia (Anonymous 2006; Blood 2001).

Welsh: Penigan Barfog

Origin/Distribution

The species is found in the mountains of southern Europe from the Pyrenees East to the Carpathians and the Balkans, with a variety disjunct in northeastern China, Korea and southeastern-most Russia (Lu and Turland 2001; Flora Europaea 2013).

Agroecology

Sweet William is a cool climate species. It prefers a rich, well-drained loamy, mildly alkaline soil in a sunny position but succeeds in most soils

including moderately dry soil and partial shade. It is propagated from seeds, cuttings or division, but seeds of cultivars will not breed true.

Edible Plant Parts and Uses

The flowers are edible, have a mild flavour and are used as a garnish for vegetable and fruit salads, cakes, desserts, cold drinks, tea and sorbet (Facciola 1990; Barash 1993; Brown 2011). The petals of Sweet William will add zest to ice cream, sorbets, salads, fruit salad, dessert sauces, seafood and stir-fries.

Botany

An herbaceous short-lived perennial, 30–60 cm tall with erect angular stems. Leaves green to glaucous, lanceolate 4–10 cm by 1–2 cm wide, apex acute, base tapering (Plates 1 and 2). Flowers (2–3.5 cm across) numerous produced in clusters at the top of the stem; bracts 4 almost as long as calyx tube, with membranous, ciliate margins; calyx tubular with acute teeth; petals 5 pink to red or purplish with a white base or variegated (Plates 1 and 2), limb ovate, bearded and apex dentate; stamens slightly exserted, ovary suboblong to ovoid, style linear. Capsule suboblong to ovoid, 4 valved, 1 cm across with smooth, compressed, brown ovoid seeds.

Nutritive/Medicinal Properties

Plant Phytochemicals

Two saponins (barbatosides A and B) were isolated from the aerial parts of *Dianthus barbatus* cv. 'China Doll'; the aglycone of each saponin was identified as quillaic acid (Cordell et al. 1977). The glycone of barbatoside A consisted of rhamnose, arabinose, fucose, xylose, galactose, glucose and one unidentified sugar, whereas the

Plate 1 Purple-white variegated flowers and lanceolate leaves

Plate 2 Red-white, variegated and pink flowers and lanceolate leaves

glycone of barbatoside B contained arabinose, fucose, xylose, mannose, galactose, glucose and three unidentified sugars. Astragalin, kaempferol-3-*O*- β -D-sophorose, D-pinitol and L-leucine were also isolated.

The floral scent volatiles of *D. barbatus* were characterized by the predominance of two compounds n-nonanal (14.7 %) and the sesquiterpene β -caryophyllene (10.3 %) (Jürgens et al. 2003). Other compounds included decanal, 1,2,3-trimethylbenzene, 1-methoxy-4-methylbenzene, hexanal, heptanal, octanal, α -phellandrene, α -pinene, benzaldehyde, β -pinene, *cis*- β -ocimene, linalool, methyl benzoate, *O*-xylene, *p*-cymene, *R*-limonene, sulcatone and (*Z*)-3-hexenyl acetate.

A single-chain ribosome-inactivating protein with RNA *N*-glycosidase activity, designated dianthin 29, was isolated from *Dianthus barbatus* leaves (Prestle et al. 1992). Dianthin 29 was found to inactivate *Escherichia coli* ribosomes.

Two saponins (barbatosides A and B) isolated from the aerial parts of *Dianthus barbatus* cv. ‘China Doll’ exhibited analgesic and antiinflammatory activities (Cordell et al. 1977).

Other Uses

Sweet William is a popular ornamental plant in gardens, planted in pots, flats or in beds. The plant produces nectar that attracts birds, bees, moths and butterflies.

Comments

Two varieties have been recognized:

- *Dianthus barbatus* var. *barbatus*. Southern Europe. Leaves broader, up to 2 cm broad
- *Dianthus barbatus* var. *asiaticus* Nakai. Northeastern Asia. Leaves slenderer, not over 1 cm broad

Origin/Distribution

Carnation is probably indigenous to the Mediterranean region, but its exact range is unknown due to extensive cultivation for the last 2,000 years.

Agroecology

Carnation is a cool climate crop. Carnation is a heliophilous and a facultative long-day plant. Temperature, light intensity and day length affect carnation growth. Optimum growth has been reported in location of high light intensity during winter and cool temperatures during summers. During summer, the optimum temperature for achieving good plant growth and flowers is between 13 and 15 °C, while during winter a relatively lower temperature 10–11.1 °C is preferred; carnation is not frost tender. Hot dry wind during summer months is very detrimental for the growth and development of plants.

A well-drained, rich sandy-loam or loamy sand soil is considered to be the most ideal for successful production of carnation. Soils with higher amount of clays or silt should be amended by incorporating organic matter or compost. The optimum soil pH is between 6.0 and 7.0.

Edible Plant Parts and Uses

Petals are edible (Facciola 1990; Barash 1993; Creasey 1999; Roberts 2000; Brown 2011; Rop et al. 2012). The flower petals have a strong smell

of cloves and are candied and used as a garnish in salads, for flavouring fruit, fruit salads, soups, punch bowl, etc. They can also be used as a substitute for rose petals in making a syrup. The petals should be removed from the calyx, and their bitter white base should be removed.

Botany

An herbaceous perennial plant growing to 50–80 cm tall with erect, branching herbaceous stem that is woody at the base. Leaves are opposite, glaucous, lanceolate to linear lanceolate 10–15 cm long (Plate 1). Flowers solitary or in few-flowered cymes, sweetly scented, bisexual, 3.5–6 cm diameter, single flowers with 5 petals, double flowers with 10–40 petals, peduncle with swollen nodes. Calyx with four leafy ovate bracteoles at the base, gamosepalous, cylindric and five dentate. Petals obovate or broadly cuneate, clawed or serrated, red, purple, orange, pink, white, yellow and green, spotted or variegated (Plates 1, 2, 3 and 4). Stamens 10 in two whorls, ovary one celled, styles two. Capsule with many seeds.

Nutritive/Medicinal Properties

Flower Nutrients and Phytochemicals

Rop et al. (2012) reported that edible flowers of *Dianthus caryophyllus* had a dry matter content (%w/w) of 11.55 %, crude protein of 6.89 g/kg and the following elements (mg/kg fresh mass (FM)): P 531.35 mg, K 3544.81 mg, Ca 491.89 mg, Mg 186.55 mg, Na 114.29 mg, Fe 9.85 mg, Mn 7.49 mg, Cu 2.88 mg, Zn 7.17 mg and Mo 0.55 mg. The flowers had total antioxidant capacity of 6.96 g ascorbic acid equivalents/kg FM, total phenolic content of 5.28 g gallic acid/kg FM and total flavonoid content of 2.27 g rutin/kg FM.

Cytosolic lipid-protein particles containing phospholipid as well as the same fatty acids were found in microsomal membranes of carnation petals (Hudak and Thompson 1997). The lipid-protein particles were also enriched in hexanal, *trans*-2-hexenal, 1-hexanol, 3-hexen-1-ol and 2-hexanol, volatiles of carnation flower fragrance that were derived from membrane fatty acids through the lipoxygenase pathway.

The flower scent volatiles of flowering carnations were differentiated by the proportion of eugenol (trace–84.1 %) and methyl salicylate (0.1–1.4 %) (Clery et al. 1999). Some modern varieties produce low levels of eugenol but higher levels of benzoic acid derivatives (methyl benzoate and benzyl benzoate) and the sesquiterpene β -caryophyllene (Clery et al. 1999; Lavy et al. 2002). At the petal emerging from the bud stage (6 days before anthesis), only five scent volatiles ($\mu\text{g/g}$) were detected in carnation cv. Eilat-detached petal extract, dominated by *p*-vinylphenol (65.5 μg) and 4-vinyl guaiacol (10 μg); the remaining volatiles included maltol (5.4 μg), guaiacol (1.1 μg) and *cis*-3-hexenylbenzoate (0.1 μg) (Lavy et al. 2002). At the mature flower opened stage (anthesis), benzoic acid (40 μg) and its derivatives, benzyl benzoate (19.7 μg) and phenylethyl benzoate (13.4 μg), predominated 4-vinyl guaiacol (16.8 μg) and *p*-vinylphenol (21.6 μg) and were

still high but the latter less than in the young flower stage. Other scent volatiles ($\mu\text{g/g}$) detected included *cis*-3-hexenyl benzoate (6.5 μg), benzyl salicylate (2.8 μg), hexyl benzoate (0.6 μg), vanillic acid (4.3 μg), methyl homovanillate (3.1 μg), coumaric acid (3.9 μg), guaiacol (1.1 μg), nonanal (1.7 μg) maltol (0.8 μg), nonanoic acid (0.6 μg) and the sesquiterpene β -caryophyllene oxide (0.8 μg). No monoterpenes were detected. The profile of the major scent volatiles in carnation flower headspace was different. The young flower contained *cis*-3-hexenyl acetate (82.3 %), 3-hexen-1-ol (9.9 %), *cis*-3-hexenyl tiglate (2.2 %), 1-hexyl acetate (0.5 %), methyl benzoate (0.2 %), nonanal (1.6 %), decanal (0.4 %), *cis*-3-hexenyl isovalerate (0.3 %), β -caryophyllene (1 %) and *cis*-3-hexenyl benzoate (0.8 %). The mature opened flower contained β -caryophyllene (23.4 %), *cis*-3-hexenyl acetate (19.6 %), methyl benzoate (17.9 %), *cis*-3-hexenyl benzoate (16.8 %), 3-hexen-1-ol (1.3 %), *cis*-3-hexenyl tiglate (1.0 %), 1-hexyl acetate (0.6 %), nonanal (0.4 %), decanal (0.5 %), *cis*-3-hexenyl isovalerate (0.3 %), phenylacetaldehyde (1.3 %), 2-hydroxy methyl benzoate (0.6 %), pentyl benzoate (0.4 %), hexyl benzoate (3.5 %), caryophyllene oxide (5.6 %), benzyl benzoate (1.7 %) and isomyl salicylate (2.6 %). Transgenic plants expressing the linalool synthase gene from *Clarkia breweri* were generated, and from their leaves and flowers, linalool and its derivatives, *cis*- and *trans*-linalool oxide, were detected.

In an another study, 12 volatiles were identified as the main components of carnation flower fragrance signature (El-Ghorab et al. 2006). The major components of the volatiles found were phenyl ethyl alcohol, eugenol, hexyl benzoate, hexenyl benzoate (z), benzyl benzoate, benzoin, nootkatone, benzyl salicylate, m-cresyl phenyl acetate, hexadecanoic acid and eicosane.

Anthocyanin flower pigments of carnations had been reported for some pink, red, red-purple and mauve cultivars. Pelargonidin 3-*O*-glycoside was found in salmon and red cultivars, pelargonidin 3,5-di-*O*-glycoside in pink, cyanidin 3-*O*-glycoside in lavender and crimson and cyanidin 3,5-di-*O*-glycoside in lavender and magenta

ones (Geissman and mehlquist 1947; Geissman et al. 1955). Cyanic carnation flowers (reds and pinks) that contained the factor *R* in homozygous or heterozygous conditioned were found to contain cyanidin glycosides; the homozygous recessive *rr* contained pelargonidin derivatives (Geissman et al. 1962). Kaempferol was clearly visible in all the red and pink genotypes and quercetin absent from these but visible in the Woburn sample. All the acyanic white genotypes contained kaempferol, but only one contained quercetin as well. Apigenin was not observed in these whites. Isosalipurposide was identified as the yellow pigment in carnation petals (Harborne 1966). Carnation genotypes with recessive (ii) alleles were found to produce yellow flowers, which contained the chalcone isosalipurposide (naringenin-chalcone-2'-glucoside) as the major petal pigment in the vacuole (Forkmann and Dangelmayr 1980). This naringenin-chalcone was the first product of the synthesis of the flavonoid skeleton and that only the conversion of naringenin-chalcone to naringenin furnishing the substrate for the further reactions to flavonol and anthocyanin. Based on the analysis of pigment composition, Onozaki et al. (1999) classified 13 white cultivars into three types: nearly pure white cultivar, 'White Mind' lacking flavonoid compounds in the petals, 'Kaly' and 'White Barbara' accumulating a large amount of naringenin derivatives and the normal white cultivars containing kaempferol derivatives as the major flavonoid. Ogata et al. (2004) reported that chalcone, which was synthesized from the condensation of *p*-coumaroyl-CoA and malonyl-CoAs by chalcone synthase, was converted to chalcone 2'-*O*-glucoside by UDP-Glc: chalcone glucosyltransferase (chalcone 2'-GT). Chalcone 2'-*O*-glucoside could then be transported and accumulated into vacuoles.

Incubation of crude extracts prepared from pink, magenta or white carnation flowering genotype with [2- ^{14}C]malonyl-CoA and 4-coumaroyl-CoA and co-chromatography on cellulose TLC plates with different solvent systems and enzymatic conversion yielded naringenin, naringenin chalcone, eriodictyol, eriodictyol chalcone, dihydrokaempferol and

dihydroquercetin (Spribille and Forkmann 1982). In carnation genotypes with wild-type alleles (R), 4'- and 3',4'-hydroxylated flavonoids were formed. Independent of the genetic state at the locus *r*, however, naringenin chalcone T-glucoside (isosalipurposide) was the only chalcone present in the flowers of genotypes which lack chalcone isomerase activity. Eriodictyol chalcone 2'-glucoside was not detected in either the flowers of genotypes with the dominant allele R or in the flowers of recessive (*rr*) genotypes. 3'-Hydroxylase activity could be readily detected in the flower extracts of all genotypes with the wild-type allele R but was completely deficient in the flower extracts of recessive (*rr*) genotypes. The gene *r* is known to control the hydroxylation pattern of the B-ring of anthocyanins. Recessive genotypes (*rr*) produced pelargonidin derivatives in the flowers, whereas cyanidin was formed under the influence of wild-type alleles R. The gene *i* is known to control the activity of chalcone isomerase. Recessive genotypes (*ii*) lacked chalcone isomerase activity, and therefore, naringenin chalcone 2'-glucoside (isosalipurposide) was accumulated. In contrast chalcone isomerase activity being present in genotypes with the wild-type allele, higher oxidized flavonoids, including anthocyanins, were synthesized. The gene *a* interferes with the anthocyanin pathway after dihydroflavonol formation but before anthocyanin synthesis. Recessive genotypes (*aa*) produced white flowers containing flavonols. Thus, six carnation genotypes were established based on chemogenetic and enzymatic characteristics (Spribille and Forkmann 1982):

- (a) IIAARR with magenta flower, producing cyanidin, isomerase and 3'-hydroxylase activities present
- (b) IIAArr pink flower, producing pelargonidin derivatives, isomerase activity present, 3'-hydroxylase activity absent
- (c) Iiaarr with white flower producing kaempferol, isomerase activity present, 3'-hydroxylase activity absent
- (d) iiAARR yellow-magenta flower producing isosalipurposide (naringenin chalcone 2'-glucoside) some cyanidin, isomerase activity absent, 3'-hydroxylase activity present

- (e) iiAArr yellow-pink flower producing isosalipurposide some pelargonidin, isomerase and 3'-hydroxylase absent
- (f) iiaarr pure yellow flower producing isosalipurposide some kaempferol, isomerase and 3'-hydroxylase absent

Malylated anthocyanins from carnation *Dianthus caryophyllus* flowers were confirmed as pelargonidin 3-*O*-(6-*O*-malyl- β -D-glucopyranoside) from red cv. 'Scania' and cyanidin 3-*O*-(6-*O*-malyl- β -D-glucopyranoside) from the purplish-red 'Nina' (Terahara and Yamaguchi 1986; Yamaguchi et al. 1988). The major anthocyanin in pink and red forms of *Dianthus caryophyllus* was identified as pelargonidin 3-malylglucoside (Terahara et al. 1986). Flowers of the red/mauve carnation cultivars 'Kortina Chanel' and 'Purple Torres' contained a macrocyclic anthocyanin pigment, a malylated cyanidin 3,5-diglucoside that readily converted by ring opening to yield cyanidin 3-*O*-(6-*O*-malyl glucoside)-5-*O*-glucoside (Bloor 1998). Cyclic-malyl anthocyanins 3, 5-di-*O*-(β -glucopyranosyl) pelargonidin 6''-*O*-4, 6'''-*O*-L-cyclic malate and a 3, 5-di-*O*-(β -glucopyranosyl) cyanidin 6''-*O*-4, 6'''-*O*-L-cyclic malate were identified from petals of deep pink and red-purple flower cultivars of *Dianthus caryophyllus*, respectively (Nakayama et al. 2000). White-flowered Sim carnations were found to contain mainly flavonol glycosides: kaempferol glycosides and naringenin glycosides and the genes dihydroflavonol 4-reductase and anthocyanidin synthase involved in flavonoid biosynthesis (Mato et al. 2000). A new macrocyclic anthocyanin, pelargonidin 3,5-di-*O*- β -glucoside(6'', 6'''-malyl diester), and 3-*O*-(6''-*O*-malylglucoside)-5-*O*-glucoside were found in 'cyclamen' red (or pink) colours in carnation flowers—cultivars Red Rox and eight others (Gonnet and Fenet 2000). Characterization of anthocyanins in the flowers of the modern carnation cv Eilat revealed that only the orange pelargonidin accumulated, due to a lack of both flavonoid 3',5'-hydroxylase and flavonoid 3'-hydroxylase activities (Zuker et al. 2002).

Wild-type carnations with a flavonoid 3',5'-hydroxylase gene were found to contain pelargonidin- or cyanidin-type anthocyanins, such as pelargonidin or cyanidin 3,5-diglucoside-6''-*O*-4, 6'''-*O*-L-cyclic-malyl diester (Fukui et al.

2003). In contrast, the anthocyanins in the transgenic flowers of cv Moondust and Moonshadow were delphinidin 3,5-diglucoside-6''-O-4, 6'''-O-L-cyclic-malyl diester (main pigment), delphinidin 3,5-diglucoside-6''-malyl ester and delphinidin 3,5-diglucoside-6'',6'''-dimalyl ester. Additionally, the petals contained flavonol and flavone glycosides. Three of them were identified to be kaempferol 3-O-(6'''-rhamnosyl-2'''-glucosylglucoside), kaempferol 3-O-(6'''-rhamnosyl-2'''-(6-malyl-glucosyl)-glucoside) and apigenin 6-C-glucosyl-7-O-glucoside-6''-malyl ester. This flavonoid exhibited the strongest copigment effect. Chalcononaringenin 2'-O-glucoside (Ch2'G) was found to be the major pigment molecule in the petals of carnations bearing yellow flowers (Yoshida et al. 2004). The concentration of this pigment varied from 5.5 to 100.0 %.

Transcription of the following genes was found in the yellow flowers: anthocyanidin synthase, anthocyanin acyltransferase, chalcone 2'-glucosyltransferase, chalcone-flavanone isomerase, chalcone synthase, dihydroflavonol 4-reductase, flavanone 3-hydroxylase, UDP-glucose:flavonoid glucosyltransferase and phenylalanine ammonia-lyase. The activity of flavanone 3 β -hydroxylase gene (FHT) was demonstrated in carnation flowers (Dedio et al. 1995). A phenylalanine ammonia-lyase (PAL) cDNA clone was isolated from carnation petals (Yoshimoto et al. 2001). The yellow colour of the carnation petals was attributed to the synthesis and accumulation of chalcone 2'-glucoside (Itoh et al. 2002). In several of the carnation cultivars that bear yellow flowers variegated with white flecks and sectors, both the chalcone isomerase (*CHI*) and dihydroflavonol 4-reductase (*DFR*) genes were disrupted by a transposable element *dTdic1*. Glucosylation of anthocyanin in carnations was found to involve novel sugar donors, aromatic acyl-glucoses, in a reaction catalyzed by the enzymes acyl-glucose-dependent anthocyanin 5(7)-O-glucosyltransferase (AA5GT and AA7GT) (Matsuba et al. 2010).

An acyl donor substance of anthocyanin malyltransferase, 1-O- β -D-malylglucose, was extracted and partially purified from carnation petals (Abe et al. 2008). This was synthesized chemically to analyse AMaT activity in a

crude extract from carnation. Changes in the AMaT activity showed close correlation to the accumulation of pelargonidin 3-malylglucoside (Pel 3-malGlc) during the development of red petals of carnation, but neither AMaT activity nor Pel 3-malGlc accumulation was detectable in roots, stems and leaves.

Three flavonol glycosides were isolated from the flowers of carnation cultivars 'White Wink' and 'Honey Moon' and their structures established as kaempferol 3-O-neohesperidoside, kaempferol 3-O-sophoroside and kaempferol 3-O-glucosyl-(1 \rightarrow 2)-[rhamnosyl-(1 \rightarrow 6)-glucoside] (Iwashina et al. 2010).

Leaf/Plant Phytochemicals

Dianthin 30 and dianthin 32, two proteins with molecular weights 29,500 and 31,700, respectively, were isolated from the leaves of *Dianthus caryophyllus* (carnation) (Stirpe et al. 1981). Both dianthins were glycoproteins containing mannose. Three gypsogenic acid glycosides including 3-O- β -D-glucopyranoside of gypsogenic acid with the trivial name dianoside A, 3,28-O-di-glucopyranoside of gypsogenic acid with the trivial name dianoside A and 3-O-glucopyranosyl,28-O-[glucopyranosyl(1 \rightarrow 6)] glucopyranoside with the trivial name azukisaponin IV were isolated from aerial parts of carnation (*Dianthus caryophyllus* var. remontan) (Gumnicka and Oleszek 1998). *Lepidium sativum* seedling root growth was affected severely at the presence of gypsogenic acid 3-O-glucopyranoside. Bidesmosidic form showed marginal stimulatory activity.

Two benzoic acid derivatives, protocatechuic acid (3,4-dihydroxybenzoic acid) and vanillic acid (4-hydroxy-3-methoxybenzoic acid), and together with the flavonol glycoside peltatoside (3-[6-O-(α -L-arabinopyranosyl)- β -D-glucopyranosyl] quercetin) were found within healthy and fungal-inoculated tissues of carnation cultivars (Curir et al. 2003a). 2,6-Dimethoxybenzoic acid was detected in small amounts only in the inoculated cultivar 'Gloriana', while the highly resistant cultivar 'Roland' showed the presence of the flavone datiscetin (3,5,7,2'-tetrahydroxyflavone).

A new enzyme, *S*-adenosyl-L-methionine:flavonoid 4'-*O*-methyltransferase (F 4'-OMT), has been purified 1,399-fold from carnation tissues (Curir et al. 2003b). Arginine decarboxylase (ADC), a key enzyme in the biosynthesis of polyamines, comprising 725 amino acids with a molecular mass of 78 kDa was found in carnation (Ha et al. 2004).

Flavonoids, kaempferol 3-*O*-β-D-glucopyranosyl (1 → 2)-*O*-β-D-glucopyranosyl (1 → 2)-*O*-[α-L-rhamnopyranosyl-(1 → 6)]-β-D-glucopyranoside; apigenin 6,8-di-C-β-D-glucopyranoside; kaempferol 3-*O*-β-D-glucopyranosyl (1 → 2) -*O*-[α-L-rhamnopyranosyl-(1 → 6)]-β-D-glucopyranoside; kaempferol *O*-diglycosides; and rutin, were isolated from carnation (*Dianthus caryophyllus*) (Galeotti et al. 2008a). One flavone-C-glycoside apigenin 6,8-di-C-β-D-glucopyranoside (vicenin-2) and two flavonol-*O*-glycosides kaempferol 3-*O*-β-D-glucopyranosyl-(1 → 2)-*O*-[α-L-rhamnopyranosyl-(1 → 6)]-β-D-glucopyranoside and kaempferol 3-*O*-[α-L-rhamnopyranosyl-(1 → 6)]-β-D-glucopyranoside (nicotiflorin) isolated as the main flavonoidal components in nine different carnation cultivars (Galeotti et al. 2008b).

Yang et al. (1997) reported that benzoyl-CoA:anthranilate *N*-benzoyltransferase catalyzed the first committed reaction of phytoalexin biosynthesis in carnation, and the product *N*-benzoylanthranilate was found to be the precursor of several sets of dianthramides. Cell suspension cultures of *Dianthus caryophyllus* was found to accumulate, upon challenge with crude fungal elicitor, various dianthramide phytoalexins, all of which were derived from *N*-benzoylanthranilate (Reinhard and Matern 1991). In-vitro, microsomes from the elicited carnation cells hydroxylated *N*-benzoylanthranilate to yield the hydroxyanthranilate and/or salicyloyl derivatives, and both these activities depended strictly on NADPH and molecular oxygen. 2'-Hydroxylation was shown to precede 4-hydroxylation in the formation of *N*-salicyloyl-4-hydroxyanthranilate. 4-Hydroxylation was shown to be catalyzed by cytochrome P-450-dependent monooxygenase(s), whereas the 2'-hydroxylating activity appeared to be due to a novel class of enzymes, also responding

synergistically to NADH in combination with NADPH and showing apparent inhibition by cytochrome c but not by carbon monoxide. The results demonstrated the requirement of two different classes of hydroxylase activities that appeared to introduce the antimycotic quality to the dianthramides for phytoalexin defence. Further, they proposed that methoxydianthramide B was derived from *N*-benzoylanthranilic acid via *N*-benzoyl-4-hydroxyanthranilic acid catalyzed by increases in *N*-benzoyltransferase and phenylalanine ammonia-lyase activities (Reinhard and Matern 1989). The rapid induction of both enzyme activities suggested that the shikimate pathway was of crucial importance in the disease-resistance response of carnation cells.

Antioxidant Activity

Treating carnation plants with 400 ppm stigmasterol gave the highest DPPH scavenging of the oil compared to other treatments (El-Ghorab et al. 2006).

Antimicrobial Activity

Two known compounds were isolated from the essential oils of aerial parts of *Thymus kotschyanus*, and flower buds of *Dianthus caryophyllus* exhibited antibacterial activity (Mohammed and Al-Bayati 2009). Thymol MIC values ranged from 15.6 to 250 µg/ml, and *Bacillus cereus* was found to be the most sensitive pathogen with an MIC value of 15.6 µg/ml. Eugenol achieved stronger MIC values against most tested pathogens, and the best MIC value (15.6 µg/ml) was observed against *Bacillus cereus*, *Listeria monocytogenes* and *Klebsiella pneumoniae*, whereas *Staphylococcus aureus*, *Proteus mirabilis* and *Escherichia coli* were inhibited with an MIC value of 31.2 µg/ml.

Antiviral Activity

The virus inhibitor from carnation was found to compose of probably ε-groups of lysine that were

responsible for the biological activity of the molecule (Ragetli and Weintraub 1962). Acid hydrolysis yielded 14 amino acids, none of which contained sulphur. The inhibitor, which had already been found to protect *Nicotiana glutinosa* from infection by either intact tobacco mosaic virus (TMV) or the infectious nucleic acid (RNA) derived from it, was shown to possess no ribonuclease (RNase) activity and to be unable to prevent enzymatic breakdown of RNA by pancreatic RNase.

Dianthin 30 and dianthin 32, two antiviral proteins isolated from the leaves, inhibited protein synthesis in a lysate of rabbit reticulocytes, with an ID₅₀ (concentration giving 50 % inhibition) of 9.15 ng/ml (dianthin 30) and 3.6 ng/ml (dianthin 32) (Stirpe et al. 1981). They acted by damaging ribosomes in a less-than-equimolar ratio. Protein synthesis by intact cells was partially inhibited by dianthins at a concentration of 100 µg/ml. Dianthins mixed with tobacco mosaic virus strongly decreased the number of local lesions on leaves of *Nicotiana glutinosa*.

Nontoxic concentration (20 µg/ml) of *Dianthus caryophyllus* seed extracts applied to both Vero and HepG2 cells showed potent antiviral activity against herpes simplex virus (HSV-1) and hepatitis A virus (HAV-27) using plaque infectivity count assay (Barakat et al. 2010). *D. caryophyllus* exhibited strong virucidal activity against HSV-1 and HAV-27, 92.3 and 92.6 %, respectively.

Anticancer Activity

In in-vitro studies, kaempferide triglycoside, a glycosylated flavonol from carnation, inhibited proliferation of native and oestrogen receptor beta overexpressing HTC8 colon cancer cells through a mechanism not mediated by ligand binding dependent oestrogen receptor activation (Martineti et al. 2010). It arrested G0/G1 phase of HCT8 cell-cycle progression. The biological effects of this kaempferide triglycoside were strengthened by the presence of high levels of oestrogen receptor beta.

Parasitic Activity

The essential oil of *D. caryophyllus* exhibited moderate larvicidal activity, displaying an LC₅₀ > 50 mg/l against the West Nile vector *Culex pipiens* (Kimbaris et al. 2012). Its component eugenol had an LC₅₀ of 18.28 mg/l.

Traditional Medicinal Uses

Carnation has been prescribed in European traditional herbal medicine to treat coronary and nervous disorders (Chevallier 1996). It is an aromatic, stimulant herb that has been used in tonic cordials in the past to treat fevers, though this use is now obsolete (Bown 1995). The flowers are reared to be alexiteric, antispasmodic, cardiotonic, diaphoretic and nervine and used as a vermifuge (Chopra et al. 1986).

Other Uses

Carnation is a very popular ornamental and cut-flower crop. Carnations are cultivated the world over for cut flowers. It has excellent postharvest quality, a wide array of forms and colours, capacity to withstand long-distance transportation and a remarkable ability to rehydrate; the carnations are preferred for commercial purpose than other flowers by growers.

An essential oil obtained from the flowers is used in perfumery (Hill 1952; Uphof 1968). The flower heads are dried and used in potpourri, scented sachets and cosmetic products (Bown 1995). The leaves can be simmered in water, and this water can then be used as a soap for cleaning the skin, clothes, etc. (Allardice 1993).

The plant also has antifungal activity. Flavonoid glycosides isolated from carnation exhibited antifungal activity against different *Fusarium oxysporum* f.sp. *dianthi* pathotypes (Galeotti et al. 2008a). Two benzoic acid derivatives, protocatechuic acid and vanillic acid; the flavonol glycoside peltatoside; and 2,6-dimethoxybenzoic acid, from carnation plant tissues, exhibited weak inhibitory activity

towards the phytopathogen, *Fusarium oxysporum* f. sp. *dianthi*, while the flavone datiscetin exhibited an appreciable fungitoxic activity towards the pathogen (Curir et al. 2003a).

Comments

Colombia is the largest carnation producer in the world; other leading producers include Israel, Kenya and Spain where carnation is the national flower (Perry 2001).

Family

Caryophyllaceae

Common/English Names

Annual Pink, China Pink, Chinese Pink, Dianthus, French Mignonette, Indian Pink, Japanese Pink, Pinks, Rainbow Pink

Vernacular Names

Burmese: Zaw-Hmwa-Gale

Chinese: Qú Mài, Shí Zhū

Euskera: Krabelin txinar

French: L'oeillet De La Chine

German: Chinenser-Nelke, Kaiser-Nelke

Japanese: Kara-Nadeshiko, Sekichiku

Korean: Kara-Nadeshiko

Philippines: Clavel (Tagalog)

Polish: Goździk Chiński

Portuguese: cravina-da-Arrábida, cravina-da-China, cravinhos-da-China

Spanish: Clavel Chino, Clavellina

Swedish: Sommarnejlika

Turkish: Çin Karanfil

Origin/Distribution

The species is indigenous to northern China (Gansu, Hebei, Heilongjiang, Henan, Jilin, Liaoning, Nei Mongol, Ningxia, Qinghai, Shaanxi, Shandong, Shanxi and Xinjiang), Korea, Mongolia, Kazakhstan and southeastern Russia and has naturalized in southern China. It is widely cultivated elsewhere in temperate and subtropical areas.

Agroecology

In its native range, the species occurs in forest edges, forest grasslands, scrub on mountain slopes, hillside grasslands, dry hillsides, sandy hill summits, valleys, rocky ravines, meadows, streamsides, mountain stream wetlands, rocks, steppes, steppe sands, fixed dunes and seashores.

The species requires well-drained, neutral to slightly alkaline soil and full sun to partial shade.

Edible Plant Parts and Uses

Like most *Dianthus*, it has a pleasant spicy, floral, clove-like taste and is ideal for decorating or adding to cakes (Barash 1993; Creasey 1999; Brown 2011; Thompson and Morgan 2013). They also make a colourful garnish to soups, salads and the punch bowl. It is advisable to remove the bitter white base of the petal.

Botany

A small, glabrous, herbaceous, perennial growing in dense tufts to 30–50 cm high with erect and distally branched stem. The leaves are green to greyish linear-lanceolate, 3–5 cm long by 2–4 mm wide, with acuminate apex, tapering base and entire margin (Plates 1, 2 and 3). Flowers, 2.5–4 cm across, solitary or in a few-flowered cymes with four ovate bracts and on

Plate 1 Pink-white flowers and leaves

Plate 2 Red flowers and leaves

1–3 cm pedicels; calyx cylindric with lanceolate 5 mm, pointed teeth; petals 1.6–2 cm; limb bright red, purple-red, pink or white, obovate-triangular, throat spotted and laxly bearded, apex irregularly dentate; stamens exserted; ovary suboblong, style linear (Plates 1, 2 and 3). Capsule suboblong with 4-toothed apex. Seeds black, oblate.

Plate 3 White flowers and leaves

Nutritive/Medicinal Properties

Plant (Aerial Parts) Phytochemicals

Two malylated anthocyanins were found in fresh petals of *D. chinensis* (Nadanasabapathy and Sayeed 1991).

Two triterpene saponins, named dianchinenosides A and B, were isolated from *Dianthus chinensis* and their structures determined as 3 β -O- α -L-arabinopyranosyl-16 α -hydroxyolean-12-ene-23 α , 28 β -dioic acid 28-O- β -D-glucopyranoside [1] and 3 β -O- β -D-xylopyranosyl-16 α -hydroxyolean-12-ene-23 α , 28 β -dioic acid 28-O-D-glucopyranoside, respectively (Li et al. 1993). Four triterpenoid saponins, dianchinenosides E, F, G and H, were from the aerial parts of *Dianthus chinensis* (Koike et al. 1994). Two triterpenoid saponins, dianchinenoside C [23-O- β -D-glucopyranosyl 3 β , 16 α -dihydroxyolean-12-ene 23 α , 28 β -dioic acid 28-O- β -D-glucopyranoside] and dianchinenoside D [3 β , 16 α -dihydroxyolean-12-ene 23 α , 28 β -dioic acid 28-O- β -D-glucopyranosyl

[(1 \rightarrow 6)- β -D-glucopyranoside] were isolated from the aerial parts of *Dianthus chinensis* (Li et al. 1994a). In addition, known compounds, 3-O- α -L-arabinopyranosyl hederagenin 28-O- β -D-glucopyranosyl (1 \rightarrow 6)- β -D-glucopyranoside, sitosterol 3 β -O- β -D-glucopyranoside, isoorientin-2''-O-glucoside, isovitexin-2''-O-glucoside and chrysoeriol-7-O-glucoside, were also identified. L-dianose, a new monosaccharide, was isolated from *D. chinensis* (Li et al. 1994b). The plant also contained melosides A and L which were first reported in melon (Monties et al. 1976; NPRI and SNU 1998; Nho et al. 2012). *Qu Mai* (dried aerial parts of *Dianthus chinensis*) was reported to contain *Dianthus* saponins A, B, C and D; volatile oil components—eugenol, phenylethyl alcohol, benzyl benzoate and methyl salicylate; phosphoric acid; vitamin A; alkaloids; and flavones (Xu 2002).

Antioxidant Activity

The methanol extract of *D. chinensis* exhibited strong antioxidant activity on the oxidation of linoleic acid (Kim et al. 1994).

Anticancer Activity

D. chinensis extract was found to have antitumour activity against Ehrlich ascites carcinoma in-vitro (Kosuge et al. 1985). Treatment of human HepG2 hepatocellular carcinoma cells with the ethanol extract of *Dianthus chinensis* significantly inhibited cell growth in vitro in a concentration- and time-dependent manner by inducing apoptosis through the mitochondrial pathway and caspase activation (Nho et al. 2012). This induction was associated with chromatin condensation and cleavage of poly (ADP-ribose) polymerase protein. Further, the extract selectively downregulates the expression of bcl-2 and bcl-xl in HepG2 cells.

Traditional Medicinal Uses

The species has been used for over 3,000 years in Chinese herbal medicine (Bown 1995). The

whole plant is a bitter tonic herb that stimulates the digestive and urinary systems and also the bowels. It is also anthelmintic, antibacterial, antiphlogistic, diaphoretic, diuretic, emmenagogue, febrifuge and haemostatic (Duke and Ayensu 1985; Bown 1995). It is used internally in the treatment of acute urinary tract infections (especially cystitis), urinary stones, constipation and failure to menstruate and externally to treat skin inflammations and swellings (Bown 1995). The old leaves are crushed and used for clearing eyesight (Duke and Ayensu 1985). *Qu Mai* (dried aerial parts of *Dianthus chinensis*) is used in Chinese herbal medicine to promote urination and menstruation, to break up blood stasis and to treat red, sore and swollen eyes (Xu 2002).

In Korea, this herb is used as a folk remedy for the treatment of menostasis, gonorrhoea and cough and as a diuretic and emmenagogue (NPRI and SNU 1998).

Other Uses

The species is popularly cultivated as an ornamental garden plant. It is excellent for beds, borders, edgings, rock gardens and pots.

Comments

Dianthus chinensis is a very variable species represented in China by both cultivated and wild plants and the most important source of herba dianthi in Shandong. Several varieties were identified in Shandong: *D. chinensis* L. var. *versicolor* (Fich. ex Link) Y. C. Ma, *D. chinensis* L. var. *versicolor* and *D. chinensis* L. var. *liaotungensis* Y. C. Chu (Zhou et al. 1997).

Origin/Distribution

The plant is indigenous to India, Southeast Asia (Kampuchea, Laos, Myanmar, Thailand, Vietnam, Malaysia, Papua New Guinea and the Philippines) and tropical Africa (Benin, Ivory Coast, Ghana, Mali, Nigeria, Sierra Leone, Togo, Tanzania, Zaire and Angola). It is now widely cultivated as ornamental and naturalized in the tropics. The plant is cultivated in China and Taiwan and has naturalized in northern Queensland and the northern parts of the Northern Territory, in New Caledonia, Southeastern United States (i.e. Florida) and the Caribbean (e.g. Puerto Rico and the Virgin Islands).

Agroecology

In its native range, it is found along edges of primary forests; in secondary forests, woodlands and hillsides; and alongside riverbanks from sea level up to 1,500 m. Elsewhere it is also found in disturbed habitats, thickets and rice fields and along roadsides and railway tracks. The plant is also cultivated in gardens as fences/hedges and in parks. The plant grows and flowers best in full sun. Although fairly drought tolerant, it requires moderate watering during the hot dry seasons. It grows on a wide range of soils, including poor soils, and does best in well-drained, moist soil rich in humus.

Edible Plant Parts and Uses

The plant has edible fruit that tastes like almond, and the flowers are eaten in Thailand (Wessapan et al. 2007; Wetwitayaklung et al. 2008). In tropical Africa and parts of Southeast Asia, it is cultivated for production of the drug (fruits and seeds) and as a leafy vegetable. In Indonesia, very young reddish-brown leafy shoots are eaten raw or steamed as 'lalab'.

Botany

A deciduous, sub-woody climber or scrambling shrub with pubescent terete branches and reaching lengths of 3–8 m. Leaves simple, oblong-elliptic to elliptic, 5–18 cm by 3–7 cm, with acuminate tips, obtuse to rounded base and entire margin, abaxially brown pilose and adaxially glabrous, rarely tomentose of both surfaces (Plate 1). Inflorescences in lax terminal racemes, 10–15 cm long, with linear-filiform to ovate, brown pilose deciduous bracts (Plates 1 and 2). Flowers fragrant, bisexual, pentamerous and tubular; calyx tube yellow pilose with five deltoid lobes 1.5–2.5 mm long with acuminate apices; petals 5 obovate to oblanceolate, 8–16 mm long, with obtuse apices, white turning to pink or red; stamens 10 in two rows, adherent, scarcely exerted, ovary inferior, style filiform and stigma knob shaped. Fruits dry capsule, 3–4 cm long,

Plate 1 Inflorescences and leaves

Plate 2 Close view of flowers

red turning to dark chestnut brown when ripe, narrowly ellipsoid to fusiform and sharply 5 ridged and usually one seeded.

Nutritive/Medicinal Properties

Flower Phytochemicals

Rutin and pelargonidin-3-glucoside have also been isolated from flowers (Nair et al. 1979). The major components detected in the flower extracts included *E*- and *Z*-linalool oxides (furanoid form); 2,2,6-trimethyl-6-vinyl-3-keto-tetrahydropyran; 2,2,6-trimethyl-6-vinyl-3-hydroxy-tetrahydropyran (linalool oxide pyranoid form); (*E,E*)- α -farnesene, *Z*-3-hexenyl benzoate and benzyl benzoate; and a tentatively identified compound quinoline carbonitrile along with some waxy components (Rout et al. 2008). Tannin (gallic acid), flavonoid (quercetin and rutin) and terpenoids (β -sitosterol and lupeol) were isolated from leaves and flowers of *Quisqualis indica* (Bairagi et al. 2012b).

Fruit Phytochemicals

The fruit was found to contain the following amino acids: arginine, aspartic acid, glutamic acid, serine, glycine, proline, leucine, valine, alanine, threonine, asparagine, histidine, lysine, an acidic amino acid named quisqualic acid along

with γ -amino butyric acid and trigollenine (Takemoto et al. 1975c). The structure of quisqualic acid was proposed as β -(3,5-dioxo-1,2,4-oxadiazolidin-2-yl)-L-alanine (Takemoto et al. 1975b). A new hydroxyureido derivative, 2-amino-3-(1-hydroxyureido) propionic acid, was obtained by an alkaline treatment of quisqualic acid, and isoquisqualic acid [β -(3,5-dioxo-1,2,4-oxadiazolidin-4-yl)alanine] was also synthesized. Quisqualic acid was synthesized from 3,5-dioxo-1,2,4-oxadiazolidine and from methyl 3-chloro-2-benzoxycarbonylaminopropionate (Takemoto et al. 1975a). Related compounds are the following: D-L-2-amino-3-(1-hydroxyureido)propionic acid and L-2-amino-4-(3-hydroxyureido)-butyric acid were also synthesized. Quisqualic acid was also found in the seeds (Flippen and Gilardi 1976). A new acylglycosyl sterol, 3-*O*-[6'-*O*-(8*Z*-octade-cenoyl)- β -D-glucopyranosyl]-clerosterol, plus 4 known compounds clerosterol, betulinic acid, methylursolate and α -xylofuranosyluracil were isolated from the methanol extract of *Quisqualis* fruit (Kwon et al. 2003). The peel of *Quisqualis* fruit was found to contain trigonelline (Iang and Tian 2004). Twelve compounds were isolated from the ethanol extracts of *Quisqualis indica* fruit (Huang et al. 2006). The compounds were glyceryl monosterate, glyceryl monopalmitate, clerosterol, 1-linoleoyl-3-palmitoylglycerol, stigmasterol, methylursolate, betulinic acid, ethyl gallate, gallic acid, butanedioic acid, benzoic acid and sucrose.

Fixed oil extracted from the fruits could be stored for a year in bottles with charcoal as desiccants and covered with polythene sheets without appreciable loss of quality (Quitana et al. 1983). However, there were significant changes in some parameters such as acid value, saponification ester values which represented degradation indices that began at 6 months but were not expressed in terms of off-flavour/odour. After a year storage, crude oil content changed from 38.347 to 30.25 %, pure fixed oil from 28.30 to 26.78 %, moisture content 7.25 to 7.83 %, weight 628 to 4.88 g, oxygen 20.64 to 19.82 %, specific gravity (25 °C) 0.924 to 0.904, refractive index (28 °C) 1.48 to 1.514, acid value 1.047 to 5.552, saponification value 201.11 to 153.89 and ester value 208.07 to 148.34.

The oil yield from *Quisqualis* fruit was 27.70 % (Wang and Chen 2004). Among the fatty acids, oleic acid, linoleic acid and palmitic acid were dominant. The unsaturated fatty acids accounted for 63.93 % of the total fatty acids, and the major saturated fatty acid was palmitic acid.

Leaf Phytochemicals

Four crystalline constituents were isolated from the leaves of shih-chun-tze, *Quisqualis indica* and identified to be nicotinic acid methylbetaine (trigonelline), L-proline, L-asparagine and potassium quisqualate (Fang and Chu 1964). Two cysteine synthase isoenzymes A and B were purified from the leaves (Murakoshi et al. 1986). Both isoenzymes catalyze the formation of cysteine from O-acetyl-L-serine and hydrogen sulphide, but only isoenzyme B catalyzes the formation of L-quisqualic acid. Two ellagitannins, quisqualin A and quisqualin B, were isolated from the fruits (Lin et al. 1997). Twenty-one additional tannins were isolated from either the fruits or leaves including 11 ellagitannins (2,3,-(S)-HHDP-D-glucose; 2,3-(S)-HHDP-4-galloyl-D-glucose; 2,3-(S)-HHDP-6-galloyl-D-glucose; 2,3-(S)-HHDP-4,6-di-O-galloyl-D-glucose, pedunculagin; punicalagin; eugenin; 1-desgalloyleugenin; casuarinin; 5-desgalloylstachyurin; and castalagin), five gallotannins (6-O-galloyl-D-glucose; 1,6-di-O-galloyl-β-D-glucose; 2,3 di-O-galloyl-D-glucose; 3,4-di-O-galloyl-D-glucose; and 4,6-di-O-galloyl-D-glucose), four phenol-carboxylic acids (gallic acid, ellagic acid, falvogallonic acid and brevifolin carboxylic acid) and one hydrolyzable tannin (punicalin). *Q. indica* leaves were reported to have 8 % moisture content, 9 % total ash, 12.5 % acid-insoluble ash, 6.55 % water-soluble ash values and 5.45 % sulphated ash (Singh et al 2011). Alcohol-soluble extractive value and petroleum ether-soluble extractive value of the leaves were observed to be 10, 3 and 1% w/w, respectively. The phytochemical test revealed the presence of alkaloids, slight amount of glycosides, tannins, flavonoids and protein in both extracts.

Antioxidant Activity

Four edible flower extracts including *Q. indica* elicited antioxidant activity in ABTS assay with the trolox equivalent antioxidant capacity (TEAC) of 0.15–0.70 (Wessapan et al. 2007). Of 24 edible Thai flowers, both dried flowers and crude extract of *Quisqualis indica* gave the highest total phenol contents and showed the highest antioxidant activities (Wetwitayaklung et al. 2008). The antioxidant activity of *Q. indica* was (TEAC=0.70, IC₅₀=13.26 µg). Total polyphenol in terms of g/100 g dried flower was 7.71 g, and 31.49 g/100 g crude extract and percent polyphenol yield was 24.47 %.

The amount of total phenolic content varied for different partitionates ranging from 22.95 to 39.45 g of GAE/100 g of dried *Q. indica* bark extract (Kaisar et al. 2009). The highest total phenolics were found in chloroform-soluble partitionate (CSP) (39.45 g of GAE/100 g of dried extract) and the lowest in the n-hexane-soluble partitionate (HSP) (22.95 g of GAE/100 g of dried extract). Total phenolic content of carbon tetrachloride (CTP) and aqueous soluble partitionates (ASP) were found to be 30.81 and 29.87 g of GAE/100 g of dried extract, respectively. Among the partitionates tested, the most potent fraction was found to be CSP. Free radical scavenging activity of the CSP was highest having IC₅₀ value of 30.65 µg/ml. CTP, ASP and HSP demonstrated moderate free radical scavenging activity with the IC₅₀ value of 68.46, 72.20 and 84.23 µg/ml, respectively, as compared to the standards, i.e. *tert*-butyl-1-hydroxytoluene (BHT) (IC₅₀=24.35 µg/ml) and ascorbic acid, ASA (IC₅₀=5.80 µg/ml).

Antidiabetic Activity

The methanolic flower extract of *Quisqualis indica* at doses of 200 and 400 mg/kg, p.o. elicited significant decrease in the biochemical parameters, glucose, triglyceride, total cholesterol, HDL-cholesterol and LDL-cholesterol levels in alloxan-induced diabetic rats as compared to

untreated diabetic control group (Bairagi et al. 2012a). The extract at both doses was also effective in normalizing the levels of triglyceride and cholesterol levels in heart homogenates as compared with diabetic control.

Antihyperlipidemic Activity

Co-administration of the methanolic or aqueous extract of aerial parts (100, 200 mg/kg) to high-cholesterol diet-induced hyperlipidemic rats reduced total cholesterol, triglycerides, low-density lipoproteins (LDL) and VLDL and increased high-density lipoproteins (HDL) (Sahu et al. 2012a). The methanol extract was more effective than the aqueous extract and was comparable to atorvastatin. The extracts were found to contain glycosides, alkaloids, saponins, flavonoids, carbohydrates and fixed oil.

Acetylcholinesterase Inhibition Activity

Wetwitayaklung et al. (2007) demonstrated that the methanolic flower extract of *Q. indica* exhibited acetylcholinesterase inhibition activity (Wetwitayaklung et al. 2007). The extract inhibited electric eel acetylcholinesterase in a dose-dependent manner with an IC_{50} value of 0.77 μ g/ml.

Antimicrobial Activity

Methanol flower extracts of five edible flowers including *Quisqualis indica* exhibited antibacterial effect in-vitro against *Staphylococcus aureus* with MIC at 50–800 μ g/ml (Wessapan et al. 2007). *Candida albicans* was inhibited by flower extracts from *Sonneratia caseolaris* and *Quisqualis indica*, with MIC at 50 and 800 μ g/ml, respectively (Wessapan et al. 2007). Four diphenylpropanoids: 1-(4-hydroxy-3-methoxyphenyl)-2-(4-allyl-2,6-dimethoxyphenoxy)propan-1-ol (1); 1-(3,4-dimethoxyphenyl)-2-(4-allyl-2,6-dimethoxyphenoxy)propan-1-ol (2);

1-(3,4-dimethoxyphenyl)-2-(4-allyl-2,6-dimethoxyphenoxy)propan-1-yl acetate (3); and 1-(4-hydroxy-3,5-dimethoxyphenyl)-2-(4-allyl-2,6-dimethoxyphenoxy)propan-1-ol (4) were isolated from the chloroform-soluble fraction of a methanol stem bark extract of *Quisqualis indica* (Jahan et al. 2009). All compounds were tested for their anti-staphylococcal activity against a total of five multidrug-resistant (MDR) and methicillin-resistant *Staphylococcus aureus* strains, and the minimum inhibitory concentrations (MICs) were in the range of 128–256 μ g/ml. Studies showed that the methanol dry flower extract of *Quisqualis indica* showed highest antimicrobial property than other flowers (*Calotropis gigantea* and *Polianthes tuberosa*) studied (Kiruthika et al. 2011). *Q. indica* methanol flower extract showed significant in-vitro antibacterial activity against the microbes *Klebsiella pneumoniae*, *Pseudomonas aeruginosa*, *Proteus mirabilis*, *Escherichia coli*, methicillin-resistant *Staphylococcus aureus* and *Bacillus subtilis*. Sanguri et al. (2011) found that *Q. indica* leaf extracts were more effective on fungal species *Alternaria porri*, *Aspergillus flavus*, *Aspergillus niger*, *Aspergillus oryzae* and *Penicillium chrysogenum* than bacterial species. The methanol extract was more effective than aqueous extract.

Antiinflammatory Activity

Oral administration of the hydroalcoholic flower extract at the doses 100 and 150 mg/kg body weight to rats elicited dose-dependent and significant antiinflammatory activity in acute (acetic acid-induced vascular permeability) and chronic (cotton pellet granuloma) inflammatory models (Yadav et al. 2011a).

Immunomodulatory Activity

Oral administration of the hydroalcoholic flower extract at the doses 100 and 150 mg/kg body weight elicited an immunomodulatory response in rats (Yadav et al. 2011b). Administration of the flower extract was found to increase phagocytic

activity by stimulation of macrophages, total WBC and differential leukocytes count. Delayed-type hypersensitivity reaction was also stimulated by *Quisqualis indica* at the higher dose significantly indicating that the extract could stimulate the haematopoietic system.

Antitumour Activity

Efferth et al. (2008) identified 25-*O*-acetyl-23,24-dihydro-cucurbitacin F as a cytotoxic constituent of *Quisqualis indica* that possessed activity against tumour cells.

Anthelmintic Activity

Quisqualic acid (from *Q. indica* fruits) at 0.1 and 0.2 % w/v and kainic and α -allokainic acid at 0.025 and 0.05 % w/v were effective in causing cessation of movement but did not kill the worms (Ishizaki et al. 1973). Pyrantel pamoate at 10–6 and 10–4 w/v had a similar effect but was also proteolytic and fatal. Quintana et al. (1983) reported that clinical tests found that adults eating 8–10 dried seeds as a single dose significant reduced ova counts of *Ascaris* and *Trichiuris*; for 9–12-years-old 6–7 seeds; for 6–8 years old 5–6 seeds; for 4–5 years old 4–5 seeds; and that children below 3 years old should not be treated with the seeds.

Forty subjects with intestinal ascariasis., aged 2–12 years old, comprising 82 % with purely *Ascaris lumbricoides* ova and 17.5 % with mixed *Ascaris lumbricoides* ova and *Trichuris trichiura* ova, were assigned to *Quisqualis indica* (niyog-niyogan) treatment and pyrantel pamoate (combantrin) treatment group at random (Carpio 1997). Follow-up fecalyses after 7 days posttreatment revealed complete cure of 85 % for *Quisqualis indica* and 90 % for pyrantel pamoate. A second dose of the corresponding anthelmintic was given which resulted in complete eradication of ova. Ten percent of the *Quisqualis indica* group developed side effects as compared to 55 % of those given pyrantel pamoate. In a randomized double-blind controlled trial involving

135 children 3–7 years old, treatment of ascariasis using ipil-ipil (*Leucaena glauca*) and niyog-niyogan (*Mesua ferrea*) plant medicines significantly produced a change in the number of ova count before and after treatment (Bonagua 1998). Both ipil-ipil and niyog-niyogan were almost similar in their effectiveness with pyrantel pamoate. The treatment was safe without any untoward effects noted.

Larvicidal Activity

Quisqualis indica was reported to have larvicidal activity against *Aedes aegypti* mosquitoes but at comparatively high doses (LC₅₀ > 263 ppm and LC₉₀ > 562.3) (Kaushik and Saini 2009).

Central Nervous System CNS Activity

Quisqualic acid, an excitatory amino acid, had been reported to be an agonist for both AMPA ((S)-2-amino-3-(3-hydroxy-5-methyl-4-isoxazole) propionic acid)-subtype glutamate receptors and metabotropic glutamate receptors such as mGluR1, mGluR3 and mGluR4 (Jin et al. 2002; Kuang and Hampson 2006; Zhang et al. 2006). These receptors are tetrameric ion channels that mediate most of the fast excitatory synaptic transmission in the mammalian central nervous system. Quisqualic acid causes excitotoxicity and is employed in neuroscience to selectively damage cholinergic neurons in the brain or spinal cord (Unger and Schmidt 1992; Muir et al. 1993; Giovannelli et al. 1998). Quisqualic acid had been reported to cause neuronal damage and seizures in animals (Zaczek and Coyle 1982). Quisqualic acid induced neuronal necrosis and glial infiltration in the stratum and hippocampus of 7-day-old rat (pups) when intracerebrally injected (Silverstein et al. 1986). An intrahippocampal injection of quisqualic acid induced hippocampal seizure in unanesthetized cats (Funda et al. 1985). The authors suggested that a mild but constant epileptogenic potency of quisqualic acid had an advantage for an experimental model of temporal lobe epilepsy in man.

Kaijima et al. (1987) found that microinjection of quisqualic acid into unilateral amygdala in chronically implanted cats resulted in various types of limbic seizures. They asserted the strict dose dependency of quisqualic acid in the production of limbic seizures to be a valid advantage for an experimental model of a complex partial epilepsy in man. Numerous wet-dog shakes were associated with limbic seizures in the course of focal epilepsy induced by kindling stimulations or local injections of kainic or quisqualic acid and progressively disappeared during generalization (Rondouin et al. 1987). Addae and Stone (1988) found that pentobarbital and diphenylhydantoin blocked the effect of quisqualic acid in the rat cerebral cortex but only at concentrations higher than the therapeutically relevant levels. Studies showed that the chloroform fraction of a hot aqueous water extract of *Quisqualis indica* inhibited cyclic AMP phosphodiesterase by about 80 % (Thein et al. 1995).

Hippocampal CA1 pyramidal cell neurons were found to be sensitized over 30-fold to depolarization by L-2-amino-4-phosphonobutanoic acid (L-AP4) following exposure to L-quisqualic acid; the phenomenon was termed the QUIS effect (Subasinghe et al. 1992). Replacement of the oxadiazolidinedione ring of L-quisqualic acid with several other types of heterocyclic rings yielded the following quisqualic acid analogues: maleimide 2, N-methylmaleimide 3, N-(carboxymethyl)maleimide 4, succinimides 5A and 5B and imidazolidinedione 6, but none of these analogues were able to mimic the effects of L-quisqualic acid and sensitize hippocampal CA1 neurons to depolarization by L-AP4. Also none of the analogues were able to preblock or reverse the QUIS effect.

Antipyretic Activity

The methanolic leaf extract of *Quisqualis indica* was found to possess significant dose-dependent, antipyretic activity against brewer's yeast induced pyrexia in Wistar rats (Singh et al 2011). The animal group that received methanolic extracts 100 and 200 mg/kg showed significant decrease in

rectal temperature from 38.40 to 37.44 and 38.99 to 37.49, respectively, as compared with the group that received aspirin, the standard drug.

Antitremor Activity

Studies in mice showed that systemic administration of excitatory amino acids, kainic acid and quisqualic acid could modify drug-induced tremor (Shinozaki et al. 1987). Kainic acid enhanced the tremor induced by tremorine but depressed the tremor induced by harmaline. Quisqualic acid depressed the tremor induced by both tremorine and harmaline in a dose-dependent manner. Kainic acid shifted the frequency of each component of the tremor induced by tremorine to the high-frequency side, but quisqualic acid did not affect the frequency of tremor of the tremor induced by tremorine. The frequency of tremor of the tremor induced by harmaline was shifted by both excitatory amino acids to the low-frequency side.

Toxicity Studies

Quisqualis indica seed has long been used in folk medicine as an ascaricide. Studies by Chivapat et al. (1998) found that mice receiving water extract equivalent to *Quisqualis indica* seed at the dose of 20.0 g/kg/day orally showed no acute toxicity and therefore LD₅₀ was more than 20.0 g/kg/day. The subacute toxicity study in Wistar rats by administration of water extract equivalent to the seed at the doses of 0.2, 2.0, 6.0, 10.0 and 20.0 g/kg/day for 60 consecutive days showed that after receiving the extract equivalent to the seed of 6.0, 10.0 and 20.0 g/kg/day for 2 days, the animals showed abnormal clinical signs; the notable ones were clonic with tonic seizures followed by respiratory arrest and death. The percentages of rats presenting toxic symptoms and death at the doses of 6.0, 10.0 and 20.0 g/kg/day in male were 26, 53 and 80, respectively, and in female were 0, 6 and 80, respectively. All rats died after receiving the highest dose only for 3 consecutive days. The growth rate and feed

consumption of the survived rats receiving the extract for 60 days were not different from control group.

Traditional Medicinal Uses

In Vietnam, the fruits are used for treatment of ascariasis and oxyuriasis in children and for treating infantile malnutrition due to intestinal parasitosis; a decoction of the fruit is used as gargle for toothache (NIMM 1999). In Thailand the seeds are used as anthelmintic and leaf for healing of abscesses (Wetwitayaklung et al. 2008). In the Philippines, the fruit is used as vermifuge and the plant as cure for cough (PBI). According to BPI, seeds macerated in oil are applied to parasitic skin diseases in China, and seeds are also used as vermifuge. In the Moluccas and India, the seeds are given with honey as an electuary for the expulsion of entozoa in children; ripe seeds are roasted and administered for diarrhoea and fever (Chopra et al. 1986; Kirtikar and Basu 1989). In Malaysia, the fruits and leaves are used as vermifuge and the roots as so in Java (Burkill 1966). A plant decoction is used for diarrhoea in children. The Malays used the leaf juice as a lotion for boils and ulcers and the leaves are applied directly for headaches. Ripe seeds are sweet and if the ovary wall and seed coat are removed are pleasant to eat but there are cases of people becoming ill on eating only two or three. Excess causes drowsiness as the seeds are soporific. The fruits and the seeds are used in Nigeria, Ivory Coast and Gabon for their anthelmintic properties and to cure diarrhoea (Burkill 1985).

Other Uses

The plant is widely grown as a medicinal plant; as an ornamental over fences, pergolas and trellises; and as hedges in gardens and parks. In West Africa, the long, flexible stems are used for basketry, fish weir and fish traps (Dalziel 1955). The plant extract exhibited mild repellency against the female oriental fruit fly *Dacus dorsalis* (Areekul and Sinchaisri 1988) *Q. indica* extract

exhibited anticoccidial effect against *Eimeria tenella* in chicken (Youn and Noh 2001).

Comments

Quisqualis indica can be propagated by leafless stem cuttings with at least three nodes: air layering and root division. Propagation from seed is easy, but fruits and seeds are seldom formed.

The plant is regarded as an emerging environmental weed in Northern Queensland and the northern parts of the Northern Territory and is a potential environmental weed or 'sleepers weed' in other warmer and wetter parts of Australia.

Thai: Ban Duek, Dok Phra Chan

Vietnamese: Bìm Trắg

Origin/Distribution

The species is indigenous to tropical and subtropical regions of the New World, from South America (French Guiana, Guyana, Surinam, Venezuela, Brazil, Bolivia, Colombia and Argentina) to Central America (Belize, Costa

Rica, Guatemala, Honduras, Nicaragua, El Salvador, Panama, Mexico) and the Caribbean (Bahamas, Cuba, the Dominican Republic and Haiti) to Florida in the Southeastern United States.

The species has become widely naturalized in the tropical regions of the world, including Asia (Indonesia, Japan (Ryukyu Islands), Brunei, Malaysia, Myanmar, Nepal, New Guinea, Philippines, Sri Lanka, Thailand) and many Pacific islands (American Samoa, French Polynesia, Hawaii, Tonga, New Caledonia, Fiji and the Galapagos Islands) and in Australia—southeastern and central Queensland and the coastal districts of northern New South Wales. It has also naturalized in Lord Howe Island and Norfolk Island.

Agroecology

The species thrives in a warm and humid climate. This species has escaped cultivation and invaded watercourses, riparian areas, moist forests, urban bushland and disturbed areas (e.g. in parks and along roadsides and railway lines) in the subtropical and tropical regions of the world.

Edible Plant Parts and Uses

Bundles of unopened flowers are sold in the markets in Brunei where the people consumed it as vegetable (Ng 2011). Young leaves and fleshy calyces are cooked or steamed and eaten as a vegetable or used in curries, soups, stews, etc. (Facciola 1990). The immature seeds are also consumed. In China, leafy shoots and fleshy sepals are eaten as potherbs; dried flowers are used for soup and also in pastries in Yunnan (Hu 2005).

Botany

A scrambling or climbing perennial or annual herbaceous liana with twining, glabrous up to 10 m long stem with soft prickles and milky sap. Leaves are alternate, large, 10–20 by 5–16 cm, ovate to

Plate 1 Moon flower (Marlene Deller)

circular in outline, entire or slightly trilobed with acuminate to mucronulate tips and cordate bases, glabrous and borne on 5–20 cm long petioles. Inflorescences in axillary helicoids cymes, 1-several flowered, peduncle stout and bracts small and deciduous. Flowers are nocturnal, fragrant, slightly zygomorphic and borne on 7–15 cm long pedicels. Sepals 5, elliptic to ovate, leathery, glabrous and strongly mucronate. Corolla salverform (trumpet shaped), tube greenish white, 7–12 cm long and 5 mm in diameter, lobes white, spreading, shallowly 5-undulate (Plate 1). Stamens 5, white and exerted. Style exerted with bilobed stigma. Ovary narrowly conical and glabrous. Fruit an ovoid capsule, 2.5–3 cm, apiculate. Seeds white, brown or black and glabrous.

Nutritive/Medicinal Properties

Nutritive information on the edible flower has not been analysed. Of six *Ipomoea* species, *Ipomoea alba* had the highest nectar volume secreted per flower (50.12 μ l), while in the other taxa, it ranged from 2.42 to 12.00 μ l (Galetto and

Bernardello 2004). All nectar samples contained amino acids and sugars. Most species had sucrose-dominant nectars. Mean nectar sugar concentration throughout the lifetime of the flower ranged from 34.28 to 39.42 % for four species including *I. alba*, except for *I. cairica* (49.25 %) and *I. rubriflora* (25.18 %).

Ipalbine, a new hexahydroindolizine alkaloid, ipalbidine and an unidentified minor alkaloid were isolated from *I. alba* seeds (Gourley et al. 1969). Three new resin glycosides, albinosides I–III, were isolated and purified from a chloroform-soluble extract of *Ipomoea alba* seeds (Cruz-Morales et al. 2012). Compounds 1–3 were found to be partially acylated branched pentasaccharides derived from three new glycosidic acids (albinosinic acids A–C).

A plant growth regulator calonyctin A was isolated from the dried leaves (Fang et al. 1993). Each molecule comprises two hydroxy fatty acid residues 3-hydroxy-2-methylbutanoic acid and 11-hydroxytetradecanoic acid or 11-hydroxyhexadecanoic acid and four 6-deoxyhexose units (three of quinovose and one of rhamnose) containing a tetrasaccharide. The long-chain hydroxy acid is linked glycosidically through its O-11 to Qui D and esterified to O-2 of Qui C, forming a macrocyclic lactone. The 3-hydroxy-2-methylbutanoic acid is ester-linked to O-3 of Qui C.

Studies showed that an organic extract obtained from *Ipomoea alba* did not show any positive influence on the progression of ligature-induced periodontitis in Wistar rats when administered according to the regimen used in the study (Barrella et al. 2012). Morphometrical analysis demonstrated that topically administered extract showed no effect on reducing bone loss when compared with the control group. In addition, the extract did not present toxicity in the single- and multidose acute toxicity assays.

The whole plant is used in treating snakebite in folkloric medicine.

Other Uses

The ancient Mesoamerican civilizations used the sap of *Ipomoea alba* morning glory vine containing organic compounds to coagulate the latex

from the *Castilla elastica* tree and the guayule plant to produce bouncing rubber balls (Wildman et al. 1943; Hosler et al. 1999). These ancient peoples' control over the properties of latex and processed rubber gave rise to the Mesoamerican ball game, a central ritual element in all ancient Mesoamerican societies.

The species is widely cultivated as an ornamental plant for its flowers. In areas too cold for winter survival, it can be grown as an annual plant. Since it is of tropical origin, it flowers best under a summer short day photoperiod.

Comments

In some countries, moonflower is deemed as an invasive species as it can cause problems in agricultural production areas. Moonflower (*Ipomoea alba*) is regarded as an environmental weed in New South Wales and Queensland. It has the potential to become a serious weed of rainforest gaps and margins and wet sclerophyll forests and riparian areas throughout the coastal districts of Queensland and northern New South Wales.

Cheilocostus speciosus

Scientific Name

Cheilocostus speciosus (J. Koenig) C.D. Specht

Synonyms

Banksia speciosa J. König, *Banksia speciosa* Koenig nom. illeg., *Costus sericeus* Blume, *Costus speciosus* (J. Koenig) Sm., *Banksia speciosus* J. König, *Costus formosanus* Nakai, *Costus speciosus* var. *hirsutus* Blume, *Costus speciosus* var. *leocalyx* Nakai, *Costus spicatus* var. *pubescens* Griseb., *Hellenia grandiflora* Retz. nom. illeg., *Planera speciosa* Giseke, *Tsiana speciosa* J.F. Gmel

Family

Costaceae, also placed in Zingiberaceae

Common/English Names

Cane reed, Crape Ginger, Crepe Ginger, Elegant Costus, Malay Ginger, Spiral Flag, Spiral Ginger, White Costus, Wild Ginger

Vernacular Names

Arabic: Quste Talkh

Chinese: Zhang Liu Tou

French: Costus Elegant

German: Kostus, Kostwurz, Kreppingwer, Malayischer Ingwer, Prachtige Kosturz, Pritge Kostwurz

Yapese: Sauer

Origin/Distribution

The species is indigenous to Peninsular Malaysia in Southeast Asia. It has been introduced and naturalized elsewhere in the tropics and also cultivated in subtropical areas. It is found in India, Antilles, Bhutan, Nepal west to south China (Guangdong, Guangxi, Taiwan, Yunnan), Indo-China, New Guinea, Australia, Hawaii and the Pacific islands.

Agroecology

In its native range, it grows wild in wet places in forest margins, mountainous regions, valleys and roadsides from near sea level to 1,700 m. It thrives in a tropical climate in areas of high humanities under partial shade on moist fertile soils.

Edible Plant Parts and Uses

The young, tender leafy shoot and young leaves are eaten as vegetables. The tender shoots when boiled in coconut milk makes a good vegetable (Burkill 1966). In Sarawak, they are fried with anchovies and 'belachan' (Voon et al. 1988; Voon and Kueh 1999). The outer part of the stem is peeled before cooking. The flowers are edible (Chan 1998) in salad or as garnish.

Rhizome of *C. speciosus* is edible (Burkill 1966) and used after cooking and are used for making syrup, and the young shoots are used as vegetable by tribals (Singh 2011). The rhizome is cooked in curries with salt, chilli, tamarind and turmeric powder and the stem crushed to yield a juice by the tribal communities in the Parambikulam Wildlife Sanctuary, Kerala, India (Yesodharan and Sujana 2007).

Botany

Erect, perennial herb growing to 1–3 m high with slightly woody base, stem slender and reddish and apex branched and spirally twisted when old. Rhizome stout, creeping horizontally. Leaves lower part surrounding the stem, tomentose, arranged in a spiral when young (Plate 1). Petiole 5–7 mm; leaf blade oblong or lanceolate, 15–20×6–10 cm, abaxially densely sericeous, base subglobose, apex acuminate or caudate-acuminate, green (creamy-white coloured in variegated cultivar) (Plate 4). Inflorescences terminal paniculate spikes, ellipsoid or ovoid, 8–15 cm; bracts bright red, ovate, 2 cm, leathery, pubescent, bracteoles pale red (Plate 2) with white flowers. Calyx tubular, red, 1.8–2 cm, apex 3 lobed. Corolla tube funnel shaped, 1 cm; lobes oblong-elliptic, 5 cm, apex white or red. Labellum white, trumpet shaped, 6.5–9 cm, apex toothed and crisped, with edges overlapping (Plate 3). Stamen petaloid, white with orange-yellow base, urceolate, pubescent. Ovary glabrous. Capsule red, globose, 1.5 cm, slightly woody with accrescent calyx. Seeds numerous black, glossy.

Nutritive/Medicinal Properties

Leaf Nutrients and Phytochemicals

The proximate nutrient composition of the leaves of *Costus speciosus* per 100 g edible portion based on analyses made in Sarawak (Voon et al. 1988;

Voon and Kueh 1999) was water 80.7 %, energy 69 kcal, protein 2.3 %, fat 1.9 %, carbohydrates 10.6 %, crude fibre 2.3 %, ash 2.2 %, P 15 mg, K 587 mg, Ca 114 mg, Mg 44 mg, Fe 2.6 mg, Mn 151 ppm, Cu 22.2 ppm and Zn 4.3 ppm. *C. speciosus* leaves were found to contain 18 % protein, 46 mg Fe, 81 mg ascorbic acid, 660 µg β-carotene,

Plate 3 Close-up of flower

Plate 4 Variegated cultivar

149 mg α -tocopherol, 75 mmol of GSH (glutathione), 4.4 g total phenols and 0.848 mg/g extract of flavonoids (Vishalakshi Devi and Urooj 2010). α -amyrinsterate, β -amyrin and lupeol palmitates were isolated from the leaves (Pai and Kulkarni 1997). The leaves of *C. speciosus* were found to accumulate phytoalexins glyceollin II and II when inoculated with a nonpathogenic strain of the fungus *Drechslera longirostrata* (Kumar et al. 1984). Flavonoid contents found in the leaves were rutin 849–1,809 $\mu\text{g/g}$, quercitrin 874–3,719 $\mu\text{g/g}$ and quercetin 0–308 $\mu\text{g/g}$ (Chang et al. 2012).

Flower Phytochemicals

Chang et al. (2011) developed a surface -assisted pressurized liquid extraction for determination of flavonoids in the flowers. Flavonoid contents found in the flowers were rutin 3,476–4,251 $\mu\text{g/g}$,

quercitrin 5,375–8,475 $\mu\text{g/g}$ and quercetin 127–374 $\mu\text{g/g}$ (Chang et al. 2012).

Seed Phytochemicals

The fixed oil of seed was found to contain palmitic acid 26.9 %, stearic acid 8.3 %, oleic acid 409.5 %, linoleic acid 20.9 %, arachidic acid 1.7 %, gadoleic acid 0.7 % and behenic acid 2 % (Nainan et al 1979). Seeds were reported to yield 6.0 % of a sweet smelling fatty oil which may find use in perfume industries (Suri et al. 1986). The fatty oil contained 55.97 % palmitic acid and 23.75 % oleic acid besides other fatty acids. The defatted seeds contained 1.91 % diosgenin (an important raw material for synthesis of steroidal hormones) and three sugars, i.e. glucose, galactose and rhamnose. *Costus speciosus* seeds were reported to contain on an average 2.4 % diosgenin on dry weight basis, thereby making the seeds desirable for commercial exploitation (Singh et al. 1982). Gamma-tocopherol was isolated from the seeds (Mahmood et al. 1985). From the seeds, an oil 8.3 % comprising palmitic and oleic acids together with diosgenin and two unidentified triterpenoids were isolated (Dixit and Srivastava 1987).

Two furostanol saponins, of costusoside I and costusoside J, were isolated from the seeds and their structures elucidated as 3-*O*-{ β -D-glucopyranosyl (1 \rightarrow 2)- α -L-rhamnopyranosyl (1 \rightarrow 2) [α -L-rhamnopyranosyl (1 \rightarrow 4)]- β -D-glucopyranosyl}-26-*O*-(β -D-glucopyranosyl)-22 α -methoxy (25 *R*)-furost-5-en-3 β , 26-diol and its 22-hydroxy compound, respectively (Singh and Thakur 1982a). β -sitosterol- β -D-glucopyranoside; prosapogenins A and B of dioscin; dioscin; gracillin; 3-*O*-[α -L-rhamnopyranosyl (1 \rightarrow 2)- β -D-glucopyranosyl]-26-*O*-[β -D-glucopyranosyl]-22 α -methoxy-(25*R*) furost-5-en-3 β ,26-diol; protodioscin and methyl protodioscin (Singh and Thakur 1982b). 3-*O*-[α -L-rhamnopyranosyl (1 \rightarrow 2)- β -D-glucopyranosyl]-26-*O*-[β -D-glucopyranosyl]-22 α -methoxy-(25*R*) furost-5-en-3 β ,26-diol on complete acid hydrolysis yielded diosgenin (44.8 %), D-glucose and L-rhamnose. Partial

hydrolysis of the same saponin afforded prosapogenin identified as trillin. Methyl hexadecanoate, methyl octadecanoate and tetracosanyl octadecanoate (Singh and Thakur 1984) were isolated from the seeds. In addition to α -tocopherolquinone and 5 α -stigmast-9(11)-en-3 β -ol, two benzoquinones were isolated from the seeds and characterized as 6-methyl dihydrophytylplastoquinone (2,5,6-trimethyl-3-(3,7,11,15-tetramethylhexadecyl)-1,4-benzoquinone) and dihydrophytylplastoquinone (5,6-dimethyl-3-(3,7,11,15-tetramethylhexadecyl)-1,4-benzoquinone), respectively (Mahmood et al. 1984).

Rhizome/Root Nutrients and Phytochemicals

Nutritive composition of the rhizome was reported as energy 286.52 g cal, moisture 89.91 %, total carbohydrate 44.51 %, crude protein 19.2 %, oil 3.52 %, fibre 12.77 %, starch 31.65 %, ascorbic acid 22.5 mg/100 g, N 3.14 %, P 0.06 %, K 1.42 %, Na 0.28 %, Mg 0.19 % and Ca 1.72 % (Singh 2011). Phenolic acid contents in the rhizomes were salicylic acid 1.79 μ g/g, vanillic acid 4.79 μ g/g and ferulic acid 2.34 μ g/g. Diosgenin content from five different localities ranged from 0.138 to 2.73 %. Antinutrient contents in the rhizome were tannins 0.03 %, phenols 0.65 % and oxalate 0.03 %.

The rhizomes were found to contain alkaloids, flavonoids, cardiac glycosides, saponins, sterols and tannins anthra-glycosides, arbutin, bitter principle, essential oils, coumarins, phenols, carboxylic acids, valepotriates, anthraquinones, steroids and sterols (Saraf 2010).

Rhizomes were found to contain 2.12 % free diosgenin in 3.86 % of total sapogenins and also tigogenin (Dasgupta and Pandey 1970). Rhizomes were found to contain lanosterol and stigmasterol and the stem callus diosgenin (Rathore and Khanna 1979); gracillin and dioscin (Tschesche and Pandey 1978). Gupta et al. (1981a) found diosgenin to be distributed in all parts of the plant besides the rhizomes. Methyl triacontanoate, diosgenin, sitosterol and two aliphatic hydroxyketones characterized as

24-hydroxyhentriacontan-27-one and 24-hydroxytriacontan-26-one (Gupta et al. 1981b), a sterol 5 α -stigmast-9(11)-en-3 β -ol (Gupta et al. 1981c), 8-hydroxytriacontan-25-one and methyl triacontanoate (Gupta et al. 1982), β -sitosterol- β -D-glucoside, dioscin, gracillin and prosapogenins A and B of dioscin (Gupta et al. 1986) were isolated from the roots. The rhizome was found to contain an antifungal principle identified as the methyl ester of *p*-coumaric acid (Bandara et al. 1988). Methylprotodioscin (furostanol saponin) (Agrawal et al. 1984) and curcumin (Gaitonde and Sapre 1989) were isolated from the rhizome. Five compounds were isolated from the rhizomes and characterized as tetradecyl 13-methylpentadecanoate, tetradecyl 11-methyltridecanoate, 14-oxotricosanoic acid, 14-oxoheptacosanoic acid and 15-oxo-octacosanoic acid together with triacontanol, 5 α -stigmast-9(11)-en-3 β -ol, triacontanoic acid, sitosterol and diosgenin (Gupta et al. 1986). Bis(2-ethylhexyl)phthalate was isolated from the rhizomes (Farooqui and Shukla 1987). Five steroidal saponins were isolated from the rhizome and elucidated as daucosterin; diosgenin-3-*O*- α -L-rhamnopyranosyl (1 \rightarrow 2)- β -D-glucopyranoside; diosgenin-3-*O*- α -L-rhamnopyranosyl (1 \rightarrow 2) [α -L-rhamnopyranosyl (1 \rightarrow 4)]- β -D-glucopyranoside; diosgenin-3-*O*- α -L-rhamnopyranosyl (1 \rightarrow 2) [β -D-glucopyranosyl (1 \rightarrow 3)]- β -D-glucopyranoside; and C22-methoxyl, C26- β -D-glucopyranosyl, C22-methoxyl-25 (R)-furost-5-ene-3 β and 26-diol-3-*O*- α -L-rhamnopyranosyl (1 \rightarrow 2) [β -D-glucopyranosyl (1 \rightarrow 3)]- β -D-glucopyranoside (Chen and Yin 1995).

Eight steroid glycosides were isolated from a methanol extract of underground parts (Inoue et al 1995). Six of them were known glycosides prosapogenin-B of dioscin, dioscin, gracillin, methyl protodioscin, methyl protogracillin and protogracillin, and the remaining two comprised a furostanol monoglycoside, 26-*O*- β -D-glucopyranosyl-(25R)-furost-5-ene-3 β , 22 ζ , 26-triol, and the other a glycoside diosgenin 3-*O*- β -D-glucopyranosyl (1 \rightarrow 3)- β -D-glucopyranoside. Six compounds were isolated from the rhizome and elucidated as diosgenin, prosapogenin B of dioscin, diosgenone, cycloartanol, 25-en-cycloartenol and octacosanoic acid (Qiao

et al. 2002). Jahfar et al. (2008) found the steroidal sapogenin, diosgenin, in the rhizomes and costunolide was isolated from the hexane extract of *C. speciosus* root (Eliza et al. 2009).

Furostanol glycoside 26-*O*- β -glucosidase, dimeric with a native apparent molecular weight of 110,000, was purified from the rhizome (Inoue and Ebizuka 1996). This enzyme was highly specific for cleavage of the C-26-bound glucose moiety of furostanol glycosides. They found that glucono-1,5-lactone, a typical β -glucosidase inhibitor, and diosgenin, an aglycone of spirostanol glycosides, strongly inhibited the enzyme activity. Flavonoid contents found in the rhizomes were rutin 2,387–3,942 μ g/g, quercitrin 934–9,064 μ g/g and quercetin 180–283 μ g/g (Chang et al. 2012).

Plant Phytochemicals

A close relationship was found between chlorophyll, soluble nitrogen, total nitrogen and reducing sugar contents with diosgenin content; however, nonreducing sugar decreased with the increase in above parameters as well as diosgenin and other metabolites (Mandal and Chatterjee 1985). Zinc inhibited whereas iron and molybdenum promoted the content of diosgenin in *Costus speciosus*. Studies found that squalene metabolized into 5 α -stigmast-9(11)-en-3 β -ol (I) via $\Delta^{9(11)}$ lanosterol rather than $\Delta^{8(9)}$ lanosterol in *C. speciosus* (Akhila et al. 1987). Radioactive-labelled studies by Akhila and Gupta (1987) found that diosgenin was biosynthesized in leaves and then translocated to all the parts of the plant. Glycosidation of diosgenin occurred in all the parts of the plant and diosgenin glycosides were stored in rhizomes, seeds and flowers. Deglycosidation of saponin was observed only in the rhizomes indicating that some enzymes present in the rhizome were responsible for the hydrolysis. 3-*O*-[β -D-glucopyranosyl-(1" \rightarrow 2')- β -D-glucopyranosyl], 27-*O*- β -D-glucopyranosyl-(25R)-spirost-5-ene-3 β ,27-diol was isolated from cell suspension cultures of *Costus speciosus*, following incubation with diosgenin (Indrayanto et al. 2001). *Costus speciosus* was reported to

produce large quantity of steroidal glycosides derived from the sole aglycone, diosgenin and cycloartenol; a product of oxidosqualene cyclase (OSC) was postulated to be a common intermediate for phytosterols of primary metabolism and diosgenin of secondary metabolism (Kawano et al. 2002).

Antioxidant Activity

In the DPPH assay, the benzene plant extract showed maximum activity with IC_{50} = 15.30 μ g/ml and no significant change when compared with standard ascorbic acid, which had IC_{50} of 16.14 μ g/ml (Nehete et al. 2010). In the total antioxidant capacity test, the methanol and benzene extract showed maximum activity with IC_{50} values of 13.43 and 12.58, respectively. The total antioxidant capacities of extracts were calculated based on the formation of phosphomolybdenum complex that was measured spectrophotometrically at 695 nm. In nitric oxide radical scavenging activity, the benzene extract showed maximum activity with IC_{50} = 12.56 μ g/ml. In the iron chelating activity, benzene extract showed maximum activity with IC_{50} = 13.41 μ g/ml as compared with ascorbic acid IC_{50} = 6.9 μ g/ml. In the hydroxyl radical activity assay, the benzene extract showed maximum activity with IC_{50} = 13.46 μ g/ml compared with 4.63 μ g/ml of ascorbic acid. The phenolic content of the benzene extract showed good correlation coefficient (R^2) for all antioxidant methods. The chloroform leaf extract was shown to have free radical scavenging activity (Chakraborty 2009). Extracts of various parts of *C. speciosus* showed significant antioxidant activity, which was partially related to its high polyphenolic content (Vijayalakshmi and Sarada 2008).

The total antioxidant capacity of the rhizome was 82.88 mg ascorbic acid equivalent/g plant extract g, total phenols 93.95 mg GAE/g plant extract and total flavonoids 9.32 mg/g quercetin/g plant extract (Jha et al. 2010). IC_{50} values of *C. speciosus* rhizome methanol extract and ascorbic acid were 50.38 and 33.32 μ g/ml, respectively, in the DPPH scav-

enging assay. In the NO scavenging assay, IC₅₀ value for the methanol rhizome extract was 97.74 µg/m and the IC₅₀ values for ascorbic acid and quercetin were higher, 18.63 and 15.97 µg/ml, respectively. Administration of either costunolide (20 mg/kg day) or eremanthin (20 mg/kg day) from *C. speciosus* rhizome, for 60 days, caused a significant reduction in thiobarbituric acid reactive substances (TBARS) level and a significant increase in reduced glutathione (GSH) content along with increased enzymatic activities of superoxide dismutase (SOD), catalase (CAT) and glutathione peroxidase (GPx) in the treated streptozotocin (STZ)-induced diabetic rats when compared to untreated diabetic rats (Eliza et al. 2010). Acute toxicity test revealed the non-toxic nature of the compounds. The results indicated the protective effect of costunolide and eremanthin from oxidative stress.

Antidiabetic Activity

Studies showed that *C. speciosus* rhizome has no significant effect in the fasting or postprandial state when freeze-dried rhizome juice was fed simultaneously with glucose in non-diabetic rats; however, when fed 30 minutes before the glucose load, it showed hypoglycaemic effect (Mosihuzzaman et al. 1994). In NIDDM (non-insulin-dependent diabetes mellitus) rats, *C. speciosus* showed significant hypoglycaemic effect when the juice was fed with simultaneous glucose load. *Costus speciosus* root extract was found to possess antihyperglycaemic, antihyperlipaemic and antioxidative effects (Bavarva and Narasimhacharya 2008). Oral administration of 300 and 450 mg/kg BW of the ethanol root extract to alloxan-diabetic rats produced a reversal of diabetes and its complications. Both doses significantly lowered blood glucose concentration (26.76, 34.68 %), increased glycogenesis and decreased gluconeogenesis, reverting glucose metabolism towards normalcy. Both doses also reversed the hyperlipidaemia by reducing plasma total lipid (12.87, 178.24 %), cholesterol (21.92, 30.77 %) and triglyceride

(25.32, 33.99 %) and improved hepatic antioxidant enzyme activities. The high dose (450 mg/kg BW) was found to have more potential antioxidant activities compared with glibenclamide. Another study showed that the hexane rhizome extract had antihyperglycaemic and hypolipidaemic activity and was able to ameliorate the diabetic state of STZ-induced male diabetic Wistar rats (Daisy et al. 2008). Oral administration of hexane extract significantly decreased plasma glucose level; glycosylated haemoglobin (HbA_{1c}), serum total cholesterol and triglyceride levels; urea; uric acid; and creatinine and at the same time markedly increased plasma insulin, tissue glycogen, serum protein and high-density lipoprotein (HDL) cholesterol levels. The hexane crude extract also restored the altered plasma enzymes aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase (ALP) and acid phosphatase (ACP) levels to near normal. The hexane crude extract was found to be more active in comparison with the ethyl acetate and methanol rhizome extracts. Oral administration of costunolide from *C. speciosus* roots to streptozotocin-induced diabetic male Wistar rats significantly reduced plasma glucose in a dose-dependent manner when compared to the control (Eliza et al. 2009). In addition, oral administration of costunolide (20 mg/kg bw) significantly decreased glycosylated haemoglobin (HbA_{1c}), serum total cholesterol, triglyceride and LDL cholesterol and at the same time markedly increased plasma insulin, tissue glycogen, HDL cholesterol and serum protein. Costunolide restored the altered plasma enzyme (aspartate aminotransferase, alanine aminotransferase, lactate dehydrogenase, alkaline phosphatase and acid phosphatase) levels to near normal. The results indicated that costunolide possessed normo-glycaemic and hypolipidaemic activity.

In a separate study, administration of chloroform, methanol and aqueous extracts of *C. speciosus* rhizomes to overnight-fasted, streptozotocin-induced diabetic rats significantly reduced blood glucose level (Rajesh et al. 2009). Similar studies conducted with oral

glucose tolerance test (OGTT) confirmed the above findings, suggesting that aqueous extract and methanol extracts of *C. speciosus* were highly effective in lowering blood glucose level comparable to glibenclamide. Results from multiple dose studies wherein the drug was administered for 14 days also confirmed the above findings, and the serum lipid profiles high-density lipoproteins (HDL), low-density lipoproteins (LDL) and very low density lipoproteins (VLDL) were found to be optimum in aqueous or methanol extracts on par with normal healthy rats or standard drug glibenclamide-treated rats.

Antihypercholesterolaemic Activity

Supplementation of the rat diet with diosgenin for a week inhibited cholesterol absorption as determined by the serum isotope ratio technique, as well as by measuring in the faeces the amount of unabsorbed radioactivity from orally administered [^3H]cholesterol (Cayen and Dvornik 1979). Diosgenin suppressed the serum and liver uptake of radioactivity from co-administered [^3H]cholesterol as well as the accumulation of liver cholesterol in the cholesterol-fed rat and was substantially more active than cholestyramine or β -sitosterol. Diosgenin decreased the elevated cholesterol in serum LDL and elevated cholesterol in the HDL fraction of cholesterol-fed rats but had no effect on serum cholesterol in normocholesterolaemic rats. In contrast to cholestyramine, diosgenin markedly increased neutral sterol excretion without altering bile acid excretion; in-vitro, diosgenin had no effect on bile acid binding. Diosgenin treatment increased hepatic and intestinal cholesterol synthesis as well as the activity of hepatic HMG CoA reductase. Diosgenin had no effect on cholesterol synthesis when added to normal rat liver homogenates. The increased unabsorbed cholesterol together with enhanced secretion of cholesterol into bile resulted in enhanced excretion of neutral sterols without affecting the biliary and fecal discharge of bile acids.

Anticancer Activity

All the tested plant extracts showed significant antioxidant and antiproliferative activities in human colon adenocarcinoma cell lines (COLO 320 DM) in a concentration- and time-dependent manner in the following descending order: *Asclepias curassavica* > *Cynodon dactylon* > *Costus speciosus* root > *Amaranthus tristis* > *Merremia emarginata* > *Ophiorrhiza mungos* > *Tabernaemontana heyneana* > *Blepharis maderaspatensis* > *Aegle marmelos* > *Achyranthes aspera* (Baskar et al. 2012).

Diosgenin, a steroidal sapogenin with oestrogenic and antitumour properties, was found to inhibit human chronic myelogenous leukaemia K562 cells proliferation via cell cycle G2/M arrest and apoptosis, with disruption of Ca^{2+} homeostasis and mitochondrial dysfunction playing vital roles (Liu et al. 2005). The antiapoptotic Bcl-2 and Bcl-xL proteins were downregulated, whereas the proapoptotic Bax was upregulated.

Hepatoprotective Activity

The rhizome extract exhibited significant hepatoprotective activity (Verma and Khosa 2009b). Administration of an ethanolic rhizome extract to carbon tetrachloride-treated rats resulted in a significant decrease in serum glutamic oxaloacetic acid transaminase (SGOT), serum glutamic pyruvate transaminase (SGPT), alkaline phosphatase (ALKP), serum bilirubin (SBLN) and liver inflammation. This was supported by histopathological studies on the liver.

Antiinflammatory/Antiarthritic Activity

Studies showed that costunolide, from *Costus speciosus* root, inhibited proinflammatory cytokines and iNOS in activated murine BV2 microglia stimulated with lipopolysaccharide (Rayan et al. 2011). Costunolide attenuated the expression of tumour necrosis factor- α , interleukin-

1,6, inducible nitric oxide synthase, monocyte chemotactic protein 1 and cyclooxygenase 2 in activated microglia. Further, costunolide suppressed MAPK pathway activation by inducing MKP-1 production. The results suggested that costunolide exhibited an ability to inhibit expression of multiple neuroinflammatory mediators attributable to its inhibition of NF κ B and MAPK activation and may have potential in the treatment of neuroinflammatory diseases.

The ethanolic rhizome extract of *Costus speciosus* was found to possess antiinflammatory activity (Binny et al. 2010). Significant anti-inflammatory effect was found against carrageenan-induced oedema formation in rats at a dose of 800 mg/kg and against cotton pellet granuloma formation in rats at doses of 400 and 800 mg/kg. It showed slight antipyretic property at 800 mg/kg dose in yeast-induced pyrexia in rats. *Costus speciosus* was found to have significant anti-arthritic properties in Freund's adjuvant-induced arthritis test in adult Albino rats (150–200 mg) (Srivastava et al. 2012). The methanol extract of aerial plant parts in doses of 400 and 800 mg/kg showed 75.50 and 68.33 % protection against increase in rat paw oedema, respectively.

Antinociceptive Activity

The aqueous and ethanol rhizome extracts of *C. speciosus* exhibited significant peripheral antinociceptive actions against acetic acid-induced writhing in Swiss albino mice (Bhattacharya and Nagaich 2010). The aqueous extract significantly inhibited writhes at the dose of 75 and 150 mg/kg body weight, while ethanol extract produced significant protection at the dose of 150 mg/kg body weight. However, in the tail-flick method, only the ethanol extract showed significant central analgesic action, while the aqueous extract was totally ineffective.

Antimicrobial Activity

Among the plants tested, *Costus speciosus* and *Calendula officinalis* showed the highest anti-dermatophytic activity of 0.24 and 0.27 mg/ml,

respectively, against *Trichophyton rubrum* and *Trichophyton mentragrophytes* obtained from patients having skin diseases (Malabadi and Kumar 2005). Ethanol extracts of plants exhibited more activity than water extracts. Hexane and methanol extracts of leaf and rhizome extracts of *C. speciosus* but not the water extracts exhibited antibacterial activity against pathogens isolated from infected burn patients (*Shigella*, *Staphylococcus aureus*, *Escherichia coli*, *Klebsiella pneumoniae*, *Pseudomonas*, *Bacillus subtilis* and *Salmonella* sp.) (Malabadi 2005). The results were comparable to the conventional antibiotic cream, namely, silver sulphadiazine. *p*-coumaric acid methyl ester was found in the rhizome of *C. speciosus* as a constitutive principle with antifungal activity against plant pathogenic fungi *Cladosporium cladosporioides*, *Colletotrichum gloeosporioides*, *Curvularia* sp. and *Penicillium* sp. (Bandara et al. 1988). Antifungal activity of steroid saponins and sapogenins from *C. speciosus* was investigated by Singh et al. (1992) on six species of plant pathogenic fungi at different concentrations. Saponin B was found to be highly effective against conidial germination of *Botrytis cinerea* and *Alternaria* sp.

The water extract of *C. speciosus* rhizome was found to inhibit the growth of *Staphylococcus aureus* (Swarnkar and Katewa 2009). *Costus speciosus* (stem and flower) extract exhibited antituberculosis activity with MIC of 800 μ g/ml against *Mycobacterium tuberculosis* H37Rv (Mohamad et al. 2011). The aqueous rhizome extract showed antibacterial activity against *Staphylococcus aureus* (Saraf 2010).

C. speciosus rhizome extract was found to be active against pathogenic strains of Gram-positive (*Staphylococcus aureus*, *Staphylococcus epidermidis*) and Gram-negative (*Escherichia coli*, *Pseudomonas aeruginosa*, *Salmonella typhimurium*) bacteria, and its activity was compared to the standard antibiotic gentamicin (Ariharan et al. 2012). Antimicrobial activities were observed in hexane, chloroform, ethyl acetate and methanol extracts of *C. speciosus* rhizome (Duraipandiyan et al. 2012). The methanol rhizome extract inhibited the growth of *Staphylococcus aureus*, *Staphylococcus*

epidermidis and *Bacillus subtilis*. Two sesquiterpenoid compounds were isolated (costunolide and eremanthin) from the hexane extract. Both compounds inhibited the tested fungi but not tested bacteria. The compound costunolide showed significant antifungal activity. The MIC values of costunolide were 62.5 µg/ml against *Trichophyton mentagrophytes*, 62 µg/ml against *Trichophyton simii*, 31.25 µg/ml against *Trichophyton rubrum* isolate 296, 62.5 µg/ml against *Trichophyton rubrum* isolate 57, 125 µg/ml against *Epidermophyton floccosum*, 250 µg/ml against *Scopulariopsis* sp., 250 µg/ml against *Aspergillus niger*, 125 µg/ml against *Curvularia lunata* and 250 µg/ml against *Magnaporthe grisea*.

Uterine Stimulant Activity

Studies found that the ethanol rhizome extract (10 mg/100 ml) increased spontaneous rat uterine contraction (Lijuan et al. 2011). They found that *C. speciosus* stimulated phasic activity in the rat uterus. It was able to increase contraction via calcium entry on l-type calcium channels and sarcoplasmic reticulum (SR) calcium release. Their data suggested that the uterotonic effect was due to nonoestrogenic effects and not those of diosgenin. They suggested that *C. speciosus* rhizome extract may be a useful uterine stimulant. This uterine activity of the plant supported its use as an ecboic in the indigenous system of medicine.

Spasmolytic Activity

An alkaloid extracted from *C. speciosus* rhizomes was found to have papaverine-like smooth muscle relaxant and antispasmodic activities (Bhattacharya et al. 1973).

Anticholinesterase Activity

C. speciosus alkaloids exhibited anticholinesterase activity in both in-vitro and in-vivo tests, elucidating earlier observed potentiation of acetylcholine responses on frog rectus muscle and dog blood pressure (Bhattacharya et al.

1972). The use of the plant in eye diseases and as a depurative may be due to the anticholinesterase activity of the plant alkaloids.

Oestrogenic Activity

Saponins isolated from the rhizomes of *Costus speciosus* exhibited oestrogen-like action on spayed albino rats (Singh et al. 1972). They significantly increased the uterine weight and uterine glycogen concentration and produced proliferative changes in the uterus and vagina. The results were comparable with those produced by stilboestrol. Administration of the methanol rhizome extract at two different doses (250, 500 mg/kg body weight) for 10 days to Gonado-intact female adult mice elicited a significant decrease in ovarian weight and increase in uterine weight in comparison to normal control (Najma et al. 2012). Phytochemical screening revealed the presence of secondary metabolites, i.e. alkaloids and flavonoids. Tewari et al. (1973) reported the oestrogenic activity of 1,600 µg diosgenin isolated from *C. speciosus* rhizome was approx. equal to that of 150 µg neoclinestrol.

Adaptogenic Activity

The alcoholic rhizome extract was found to possess normalizing activity against cold immobilization stress-induced changes in norepinephrine (NE), dopamine (DA), 5-hydroxytryptamine (5-HT), 5-hydroxy indole acetic acid (5-HIAA) and enzyme monoamine oxidase (MAO) in Wistar albino rats (Verma and Khosa 2009a). The results provided biochemical evidence for the antistress activity of the tested extract Tewari et al. (1973).

Antifertility Activity

A mixture of saponins isolated from *C. speciosus* rhizomes effectively protected against pregnancy in rats, when fed at 5–500 µg/100 g body weight for 15 days (Tewari et al. 1973).

Traditional Medicinal Uses

Costus speciosus is an ayurvedic drug plant of repute used to treat various ailments (Bhogaonkar et al. 2012), possessing astringent, aphrodisiac, purgative, anthelmintic, depurative, febrifuge and expectorant properties (Srivastava et al. 2011). All plant parts of the plant are used in folk medicine in various parts of India; its extracts are used for treatment of fever, snake bites and jaundice and as a purgative, astringent and anti-bacterial agent (Nehete et al. 2010). This plant is widely used for fertility control in women by the rural people of Rangia Subdivision of Kamrup District, Assam (Najma et al. 2012). The plant is referred in the Kama Sutra as a cosmetic ingredient to be used on women's eyelashes to increase sexual attractiveness. In ayurveda, the rhizomes are ascribed to be bitter, astringent, acrid, cooling, aphrodisiac, purgative, anthelmintic, depurative, febrifuge, expectorant, tonic and aphrodisiac; useful in vitiated conditions of khapa and pitta, burning sensation, flatulence, leprosy, skin diseases, catarrhal fever, colds, worm infections, pneumonia, rheumatism, dropsy, urinary diseases, jaundice bronchitis, inflammations, coughs, dyspepsia rash, asthma and anaemia (Burkill 1966; Warriar et al. 1995; Singh 2011). The plant is administered for gout; the leaves are given in mental disorders and crushed leaves are applied in fever; decoction of stem is used in fever and dysentery. Hexane, methanol and water extracts of leaf and rhizome extracts of *C. speciosus* are used by Indian traditional healers for treating skin diseases, diabetes, jaundice, snake bites and/or antiinflammatory properties (Malabadi 2005).

According to Burkill (1966), in Peninsular Malaysia, the juice of the rhizome is used as a purgative and for syphilis and after confinement in Java and the stem is given for dysentery. The juice from the shoot or pith is squeezed into the eyes for eye complaints. The Malays eat the rhizome with betel for cough but used it to a greater extent externally. In Peninsular Malaysia and Sarawak, the plant or rhizome is boiled in water for use in bathing to treat high fever (Burkill 1966; Chai 2006). The leaves are crushed and use

as poultice on the head; the stem is scraped and the scrapings applied to leprosy skin and decoctions of stem scrapings are used as lotions for small pox and fever (Burkill 1966). The plant is cooling and sudorific. The Malays regard it when used medicinally, as exorcising evil spirits which have taken possession of the body. In Java, the rhizome is used for treating nephritis–beriberi–oedema due to hardening (sclerosis) of the liver, difficulty in urination and pricking pain in the urinary tract (Stuart 2012). A decoction of dried or fresh material decoction may be used as external application for nettle rash. A decoction of the dried rhizome is taken for stomachache and dyspepsia. In Visayas, juice of stems is used for dysentery. The juice from the stem is employed for diarrhoea.

Other Uses

Commonly grown as an ornamental. The whole plant has medicinal properties due to the presence of diosgenin, a steroid which is used as a precursor for the preparation of steroidal drugs (Singh 2011). *C. speciosus* rhizome is used to stupefy fish by the Gond tribe of Kawal Wildlife Sanctuary, Andhra Pradesh, India (Murthy et al. 2010).

The plant also has insecticidal property. Diosgenin from *C. speciosus* was found to have a low contact and ovicidal activity but a potent insect growth regulator (IGR) and high oviposition deterrent activity of diamondback moth, *Plutella xylostella* (Pipithsangchan and Morallo-Rejesus 2005). It caused larval and pupal deformities, reduced fecundity and partial sterility. Based on the ED₅₀, crude diosgenin was more active than purified diosgenin. The diamondback moth parasitoid, *Cotesia plutellae*, was 14 times less sensitive to diosgenin compared to diamondback moth.

Comments

The plant is easily propagated from rhizome divisions and stem cuttings.

Costus barbatus

Scientific Name

Costus barbatus Suessenguth

Synonyms

None recorded

Family

Costaceae

Common/English Names

Hawaiian Torch Ginger, Red Tower Ginger, Red Velvet Ginger, Spiral Ginger

Vernacular Names

Spanish: Apagafuego, Cana De Jabali, Sangrafu

Origin/Distribution

The species is a native of Costa Rica, Central America.

Agroecology

The plant grows well in full sun or partial shade in fertile, moist, well-drained, organic matter-rich soils. It blooms year round in the warm humid tropics. It tolerates cold temperatures but not frost. It is found from 600 to 1,600 m altitude in its natural habitat in Costa Rica.

Edible Plant Parts and Uses

Yellow flowers are edible (Carle 1995) and have a delightful sour lemony flavour. Flowers can be eaten straight off the plant and are excellent in a salad.

Botany

An erect, clumping herbaceous terrestrial with subterranean rhizome, growing to 1.5–2.5 m high. Ligule 10–30 mm, obtuse and lobed encircling the stem. Leaves spirally arranged with narrowly elliptic dark green lamina, 13–30 cm by 4.5–10 cm wide, simple, entire margin with a glabrous upper surface and slightly villose beneath (Plate 1). Inflorescence terminal ovoid to fusiform 4–10 cm by 2.5–4.5 cm across with numerous mucronate, bright red appendaged

Plate 1 Flowers, inflorescences and foliage

bracts each bearing 1–2 tubular flowers in their axils (Plate 1). Flowers with short calyx tube 13–17 mm, corolla yellow, densely pubescent with tubular labellum 26 by 24 mm.

Nutritive/Medicinal Properties

In ‘Suriname’s traditional medicine’, an extract of the stem is used against gonorrhoea, common cold and eye problems and as a laxative.

Other Uses

It is a common cultivated *Costus* species and a very popular ornamental and provides beautiful cut flower.

Comments

The plant is readily propagated from division of the rhizomes or from stem cuttings.

Costus erythrophyllus

Scientific Name

Costus erythrophyllus Loes.

Synonyms

Costus claviger Benoist

Family

Costaceae

Common/English Names

Blood Red Spiral Costus, Oxblood Ginger, Violet Spiral Flag

Vernacular Names

German: Rotblättriger Spiralingwer, Rotblättriger Zieringwer

Origin/Distribution

The species is a native of Amazonian Peru and Ecuador.

Agroecology

The plant thrives in a tropical/subtropical climate. It grows in a humus-rich, well-drained, friable, moist soil in partial or fully shaded position.

Edible Plant Parts and Uses

The flowers have been reported edible (Carle 1995; King 2007).

Botany

An unbranched rhizomatous perennial 0.3–1 m with leaves spirally disposed and mostly crowded at the apex, shortly petiolated, glabrous, obovate-oblong, 1.5–2.5 dm by 5.5–10 cm, upper surface green, lower surface burgundy, glabrous to sparsely puberulous, base cuneate, apex acute to acuminate, margin entire (Plates 1 and 2). Sheath is green glabrous with deeply 2 unequally lobed ligule. Inflorescence a sub-capitate spike, terminal on leafy shoot arising from the rhizome, all bracts dark red, broadly ovate with reflexed apices and foliaceous, green appendages, 2.5–6 cm by 2–4 cm, triangular ovate, foliaceous, bracteole red, puberulous. Flower calyx with red deltoid lobes, puberulous, corolla white glabrous tubular, labellum arched, spreading, middle lobe trilobulate,

Plate 1 Leaves with distinct green upper and burgundy lower surfaces

Plate 2 Flowers with red, yellow and white streaks and blotches

broadly ovate, white with central yellow zone, reddish streaks, 6–6.5 cm, stamen 4–5 cm long, with pinkish white anther, 9–10 mm long (Plate 2).

Nutritive/Medicinal Properties

No information has been published on the plant nutritive or medicinal properties.

Costus is traditionally used in Guinean, Brazilian and Trinidadian traditional medicine for various uses, as well as in the Dominican Republic and the United States for diabetes.

Other Uses

A popular ornamental plant for parks, gardens and house gardens.

Comments

The plant is propagated by division of the rhizome.

Costus productus

Scientific Name

Costus productus Gleason ex Maas

Synonyms

None recorded

Family

Costaceae

Common/English Names

Costus, Costus Ginger, Dwarf Orange Ginger, Orange Tulip Ginger, Spiral Ginger

Vernacular Names

None known

Origin/Distribution

The species is indigenous to Peru.

Agroecology

The plant thrives in a warm, humid tropical environment under partial to dappled shade. This plant cannot tolerate dry conditions and requires additional watering during the dry seasons. It prefers acidic to neutral, well-drained fertile sandy-loam soils rich in organic matter.

Edible Plant Parts and Uses

The orangey-yellow flowers are edible with a sweet, subtle fragrance and flavour and make an ideal garnish for salads (Carle [1995](#); Campbell [2006](#); NTB [2013](#)).

Botany

A rhizomatous unbranched evergreen perennial herb, 60–100 cm. Stem arising erect from the rhizome, near base covered with leafless sheaths, leafy higher up. Leaves sessile spirally arranged on the upper quarter of the stem with closed, hirsute ligulate sheaths (Plates [1](#) and [2](#)). Leaf blade, narrowly obovate to oblong, 20–25 cm by 6–10 cm wide, apex acute to acuminate and base cuneate to obtuse, upper surface glabrous, lower

Plate 1 Inflorescence and foliage of Orange Tulip Ginger

Plate 2 Sessile spirally arranged leaves and terminal inflorescence

Plate 3 Orange flowers emerging from the red bracts

sparsely pubescent, dark glossy green above, grey green below. Inflorescences terminal on leafy stem (Plate 2), with numerous scarlet, glossy, stiff, appendaged bracts, each bearing a

tubular flower with scarlet calyx tube, with tubular yellow orange corolla, labellum and stamen orange fringed with scarlet apex (Plate 3).

Nutritive/Medicinal Properties

Nutritive information of the edible plant parts and/or medicinal properties of the plant have not been published.

Other Uses

Being a low growing plant it makes a great ground cover in outdoor landscape in parks, gardens and houses. It can also be grown in containers.

Comments

The plant can be propagated from division of the rhizomes or from stem cuttings.

Doryanthes excelsa

Scientific Name

Doryanthes excelsa Corrêa

Synonyms

Agave australis (Haworth) Steudel, *Furcraea australis* Haworth

Family

Doryanthaceae also place in Agavaceae

Common/English Names

Flame Lily, Giant Lily, Globe Spear Lily, Guinea Lily, Gymea Lily, Illawara Lily, Spear Lily

Vernacular Names

None recorded

Origin/Distribution

The Gymea Lily is indigenous to the coastal areas of New South Wales near Sydney, Australia.

Agroecology

The Gymea Lily grows in open dry sclerophyll forests and woodlands in the coastal areas of New South Wales on sandy soils derived from sandstone containing some clay. It thrives in dry climate but prefers well-drained, deep soil and full sun. It is a pyrogenic flowering species and rely on post-bush fire flowering and the production of nondormant seeds to exploit favourable post-fire establishment and growth conditions. Germination of seedlings occurs some 2.5–3 years after the passage of the fire.

Edible Plant Parts and Uses

The Gymea Lily provides a traditional bush food for the aborigines in the coastal areas of New South Wales (Cribb and Cribb 1976; Low 1989). The root, stem and flower spike are edible after some preparation. The stems and roots can be harvested, roasted and eaten or made into a cake. The young flower spikes (about 0.5 m high) can be roasted and eaten. The flowers are soaked in water to produce a sweet, high energy drink.

Botany

A large perennial rosette, clumping plant with a bulbous rhizome and a tussock of long thick, bright green linear, swordlike, glabrous, fibrous,

Plate 1 Large clumping plant habit

ensiform leaves up to 1.5 m long and 10 cm wide (Plate 1). It produces a flower spike 2–5 m high, which at its apex bears a large compact terminal head of bright red trumpetlike flowers, each 10 cm across (Plates 2 and 3). Each flower has 6 narrow, lanceolate-oblong tepals 6–12 cm long by 0.6–0.9 cm wide fused at the base and surrounded by deep red bracts; anthers 27–38 mm long, green-yellow; filaments to twice as long as anthers; ovary inferior with 3-locules, style furrowed with 3-angled stigmas. Within the central well formed by the tepals, septal nectaries are formed at the base of the tepals at the top of the ovary. These nectaries exude a sweet viscous jellylike fluid that attracts honey eaters and ensures fertilization. Fruit is a dry woody capsule, ellipsoid to ovoid 7–10 cm long, red-brown at maturity containing numerous reddish-brown seeds 15–23 mm long.

Plate 2 Flowering spikes with very long peduncles

Nutritive/Medicinal Properties

No information on the nutrient composition of the edible parts, and medicinal uses or properties of the plant have been published.

Other Uses

A good rockery landscape plant. The massive flower spikes that reach up to 8 m are highly sought after for cut-flowers and foliage in the floriculture industry. The commercial value of cut-flower and foliage of *Doryanthes*, currently all cut from harvested from wild natural bush areas, is steadily increasing, as is the export demand for these unique flowers.

Plate 3 Close-up of terminal flower head

The leaves contain fibres and are split and fibres used for brush and string making, and bag and mat weaving.

Comments

The plant is propagated by division of established plants or from seeds.

Acacia cultriformis

Scientific Name

Acacia cultriformis A.Cunn. ex G. Don (Plate 3)

Vernacular Names

None recorded

Synonyms

Acacia cultrata Paxton, *Acacia cultriformis* A. Cunn. ex G. Don var. *albicans* hort. ex Chopinet, *Acacia cultriformis* A. Cunn. ex G. Don var. *glaucescens* hort. ex Chopinet, *Acacia glaucifolia* Meisn., *Acacia glaucophylla* F. Cels, *Acacia glaucophylla* Lemaire, *Acacia papuliformis* A. Cunn. ex Loudon, *Acacia papuliformis* G. Don, *Acacia scapuliformis* A. Cunn. ex G. Don, *Racosperma cultriforme* (G. Don) Pedley

Origin/Distribution

The species is native to some parts of eastern Australia, in the sub-coastal and inland parts of New South Wales and southern Queensland. It has sparingly naturalized in the Canberra region and naturalized beyond its native range in the coastal districts of northern and central New South Wales. The species has been distributed and cultivated elsewhere and has naturalized in New Zealand, Asia, Africa and North and South America.

Family

Fabaceae also placed in Mimosaceae

Common/English Names

Dog-Tooth Wattle, Dogtooth Wattle, Half-Moon Wattle, Golden-Glow Wattle, Knife Acacia, Knife Edge Wattle, Knife-Leaf Wattle, Knife-Leaved Wattle, Knife-Leaved Wattle, Knife Wattle

Agroecology

The species adapts to a warm temperate climate. The plant is suited to a wide range of soil types provided they are reasonably well drained. However, it becomes chlorotic on exceedingly limey soils. In its native range, it is found on arid rocky ridges along the coasts and inland. A position in full sun or light shade is suitable and the species is highly drought, salt and wind tolerant and moderately tolerant to mild frosts.

Edible Plant Parts and Uses

The flowers are edible cooked and can be used in fritters (Cribb and Cribb 1976).

Botany

Acacia cultriformis is a medium-sized, erect, spreading shrub up to 2–4 m tall with angled or terete branchlets. A cascading or prostrate form of unknown origin is also cultivated. The phyllodes are glabrous, greyish-green or subglaucous, triangular in shape (Plates 1 and 2), 1–3 cm long by 0.5–1.5 cm wide, apex with a small point (mucro), base asymmetric. Inflorescences 2–25 in an axillary raceme; axis 1–8 cm long; peduncles mostly 2.5–5 mm long, glabrous; heads globose to oblong, 3–7 mm long, 13–40-flowered, bright yellow (Plates 1 and 2). Pods straight to slightly curved, glabrous, sometimes pruinose, flattish, 3–10 cm long, 4–7.5 mm wide, constricted between seeds. Seeds longitudinal with expanded funicle.

Nutritive/Medicinal Properties

No nutritive composition of the edible flowers has been published.

Leaves and stems were found to contain 0.02–0.07 % alkaloids including tryptamine and β -phenethylamine; the unripe seed pods and seeds 0.04 % (White 1944, 1951, 1957). An indolealkylamine compound 5-methoxy-*N,N*-dimethyltryptamine (5-MeO-DMT) was tentatively identified from the phyllodes, stems and flowers (Appleseed 1996, cited by Trout et al. 2007). The compound 5-methoxy-*N,N*-dimethyltryptamine (5-MeO-DMT) belongs to a group of naturally-occurring psychoactive indolealkylamine drugs (Shen et al. 2010). It acts as a nonselective serotonin (5-HT) agonist and causes many physiological and behavioural changes.

Seed globulins of *A. cultriformis* were found to have varying proportions of amino acids

Plate 1 Sessile, deltoid, greyish-green phyllodes and globose flower heads

Plate 2 Close view of yellow globose flower heads

Plate 3 Plant label

glutamic acid, isoleucine, threonine and valine (Pettigrew and Watson 1975).

Seeds were reported to contain S-carboxyethylcysteine, S-carboxyethylcysteine sulfoxide, S-carboxyisopropylcysteine, α -amino- β -acetylaminopropionic acid, albizzine, djenkolic

acid, djenkolic acid sulphoxide, γ -glutamyl-djenkolic acid, pipelicolic acid, 4-hydroxy-pipelicolic acid and 5-hydroxy-pipelicolic acid (Evans et al. 1977). Studies by Falade et al. (2012) reported that S-carboxyethylcysteine negatively affected casein protein utilization by rats.

The heartwood was found to contain flavan-3 4-diols: flavan-3,3',4,4',7-pentaols (mollisacacids) of (2*R*,3*S*,4*R*)- and (2*R*,3*S*,4*S*)-configurations, and stereochemically analogous pair of flavan-3,4,4',7-tetraols (guibourtacacids) and the 8-*O*-methyl derivatives of (2*R*,3*S*,4*R*)-flavan-3,4,4',7,8-pentaol (teracacids) and (2*R*,3*S*,4*S*)-flavan-3,3',4,4',7,8-hexaol (melacacids) (Du Preez and Roux 1970).

Other Uses

Acacia cultriformis is one of the most widely cultivated wattles because of its attractive, unique, triangular foliage and bright yellow blooms. The flowers and foliage are much used in floral arrangements. The flowers are attractive to bees and other pollinators. A yellow dye is extracted from the flowers and green dye extracted from the seed pods (Grae 1974). Plants are heavily armed with thorns and make a good highway screen barrier or protective hedge in residential gardens in warm temperate areas.

Comments

The plant is readily established from seeds following pretreatment by soaking in boiling water or by scarification. Cuttings may be successful

but this is less employed. Propagation of the prostrate form would need to be carried out from cuttings in order to retain the prostrate habit.

Acacia longifolia

Scientific Name

Acacia longifolia (Andrews) Willd.

Synonyms

Acacia longifolia (Andrews) Willd. var. *typica* Benth., *Mimosa longifolia* Andrews, *Mimosa macrostachya* Poir., *Phyllodoce longifolia* (Andrews) Link. *Racosperma longifolium* (Andrews) C. Mart

Family

Fabaceae, also placed in Mimosaceae

Common/English Names

Acacia Trinervis, Aroma Doble, Golden Wattle, Coast Wattle, Sallow Wattle and Sydney Golden Wattle Golden Wattle, Long-Leaved Wattle, Sallow Wattle, Sydney Golden Wattle

Vernacular Names

None recorded

Origin/Distribution

The species is indigenous to native to south-eastern Australia, from the extreme southeast of Queensland, eastern New South Wales, eastern and southern Victoria. It is now widely cultivated in subtropical areas globally.

Agroecology

In its native range, it is found in heath and sclerophyll forest and on coastal headlands, sand dunes, riparian habitats and adjacent alluvial flats up to 150 m.

Edible Plant Parts and Uses

Flowers are edible, cooked or eaten in fritters (Cribb and Cribb 1976).

Acacia species used by the bushfood industry in Australia for the edible wattle seeds, ground seed products and occasionally flowers include *A. longifolia* var. *sophorae* (elegant wattle, coast wattle) (Plate 3) (Hegarty et al. 2001). Well-roasted, high-quality wattleseed will have a coffee, chocolate and hazelnut characteristics (Cherikoff 2011). Typical uses of wattleseed include ground, extract and paste (Cherikoff

2011). Ground wattle seeds are used in pancake batter, desserts (mousse, creme brulee, anglaise) and baked products e.g. muffins, breads and shortbread. Wattle seed extracts are added to sweet or savoury sauces, dairy desserts and as a coffee substitute.

Botany

A spreading and unarmed shrub or small tree, 2–7 m tall, with a smooth or shallowly fissured, greyish bark; branchlets angled towards the tips and with bright green, phyllodes instead of leaves. Phyllodes simple, flat, glabrous, linear-lanceolate to oblanceolate, 8–20 cm long by 1–2.5 cm wide, with 2–5 prominent longitudinal veins. Inflorescence, 1 or 2 in axil of phyllodes. Flowers yellow in a cylindrical brush like flower heads, 2–5 cm by 7 mm. Fruit 5–15 cm by 3–6 mm, straight to slightly twisted, cylindrical, constricted between seeds with a curved beak, green turning brown, containing 6–8 longitudinal seeds, each with funicle folded into a large aril (Plates 1 and 2).

Nutritive/Medicinal Properties

The following flavonoids were identified in the flowers: naringenin and 5- β -D-glycosyl-naringenin (Kerber and Silva 1993), naringenin (0.018 %w/w), a flavonone, and two of its glycosides, naringenin-5- β -D-galactoside (0.582 %

w/w) and naringenin-5- β -D-glucoside (0.2 % w/w) (da Silvia and Keber 2003). An aurone, identified as auteusidin-4-galactoside, was isolated from the ethanol extract of the flowers (Peitz and Keber 2003). *Acacia longifolia* seeds were found to contain 6–10 % water content, 12–13 % dwb protein and 19–20 % dwb in the embryo (Murray et al. 1978). The globulin protein designated G6, of molecular weight c. 250,000, comprised subunits of molecular weight 72,000, 61,000, 45,000, 36,000, 31,000, 16,000 and 11,000.

Small amounts of phenethylamine were found in the leaf, stem and flower (White 1944a, b, 1951). Flower spikes had minor alkaloid (White 1957), tryptamine itself found in some flowers (White 1951). *N-N*-Dimethyltryptamine (DMT) 0.2–0.3 % and histamine were also identified in *A. longifolia* (Hegnauer 1994).

Leaf, bark and pod extracts of *Acacia longifolia* yielded two major histamine alkaloids:

Plate 2 Close up of brush-like flower heads

Plate 1 Leaves and flower heads

Plate 3 Tree label

N-(2-imidazol-4-yl-ethyl)-*trans*-cinnamamide and *N*-(2-imidazol-4-yl-ethyl)-deca-*trans*-2, *cis*-4-dienamide in variable amounts and trace amounts in the seeds (Repke 1975). The lipidic fraction extracts of the *Acacia longifolia* wood and bark were found to contain fatty acids, fatty alcohols (minor component), sterols, steryl glucosides and steryl esters (Freire et al. 2005). The fatty acids were mainly 16:0, palmitic acid; 18:2, linoleic acid; 18:1, oleic acid; and 18:0, stearic acid. The sterols were predominantly Δ^7 sterols (spinasterol and dihydrospinasterol) and Δ^5 sterols (stigmasterol and β -sitosterol); other free sterols were campesterol, stigmastanol and β -sitostanol as minor components. The steryl glucosides found were spinasteryl glucoside, β -sitosteryl glucoside and dihydrospinasteryl glucoside in the wood and bark; and campesteryl glucoside and stigmasteryl glucoside in the wood.

Antimicrobial Activity

The ethanol leaf extract (1,000 mg), its ethyl acetate fraction and hydroethanol fractions exhibited antibacterial activity against *Staphylococcus aureus*; and moderate growth inhibitory activity against *Fusarium oxysporum* and *Cylindrocladium spathulatum* (Peitz and Keber 2003). The crude ethanol leaf extract, the ethyl acetate and the remaining ethanol fractions showed growth inhibition of *Staphylococcus aureus*, and only the crude ethanol extract showed moderate growth inhibition of *Pseudomonas aeruginosa* and did not inhibit growth of *Escherichia coli* (Peitz et al. 2003). Phytochemical screening indicated the presence of tannins, leucoanthocyanidins, flavonoids and triterpene/steroids.

Anticancer Activity

In-vitro studies showed that spinasterol had antitumorigenic potential (Villaseñor and Domingo 2000). Using the mouse skin tumour assay, spinasterol at a concentration of 15 μ g/0.2 ml acetone decreased the incidence

of skin tumours by 55.6 % and decreased the number of tumours by 65.0 % when applied immediately after croton oil.

Antidiabetic Nephropathy Activity

Studies found spinasterol to have considerable therapeutic potential in modulating the development and/or progression of diabetic nephropathy (Jeong et al. 2004). Spinasterol was found to be a potent inhibitor ($IC_{50} = 3.9 \times 10^{-12}$ g/ml, 9.5 pmol/l) of glomerular mesangial cell proliferation caused by high-ambient glucose, and its inhibitory potency was about 1,000 times higher than that of simvastatin, an HMG-CoA reductase inhibitor used as a positive control. Spinasterol also significantly reduced the increases of serum triglycerides, renal weight and urinary protein excretion in streptozotocin-induced diabetic mice.

Hypocholesterolaemic Activity

Animal studies showed that spinasterol, as well as sitosterol, inhibited cholesterol absorption, resulting in decreases of the plasma and liver cholesterol levels (Uchida et al. 1983). Further, when cholesterol absorption was inhibited, the synthesis of bile acids, especially that of chenodeoxycholic acid, decreased, suggesting that the dietary cholesterol was preferentially metabolized to chenodeoxycholic acid in mice.

Allergy Problem

Pollens are important triggers for allergic asthma and seasonal rhinitis (Hassim et al. 1998; Widmer et al. 2000). Studies showed that *Acacia longifolia* pollens released proteases that were able to cause detachment of murine airway epithelial cells from their substratum in-vitro and may not be effectively inhibited by endogenous antiproteases (Hassim et al. 1998). The intrinsic protease activity of *Acacia* pollen allergens may contribute to sensitization by disrupting the integrity of the airway epithelial barrier. In another study,

Acacia longifolia pollen diffusate was found to release proteases that exhibited high rates of cleavage of arginine and lysine substrates (Widmer et al. 2000). Disruption of epithelial integrity by proteases released following deposition of pollens on mucosal surfaces could promote sensitization and induce inflammation.

Psychopharmacological Activity

N,N-Dimethyltryptamine (DMT) is a psychedelic, hallucinogen compound. In a double-blind, saline placebo-controlled, randomized design study, intravenous administration of dimethyltryptamine (DMT) dose-dependently elevated blood pressure, heart rate, pupil diameter and rectal temperature, in addition to elevating blood concentrations of beta-endorphin, corticotropin, cortisol and prolactin in experienced hallucinogen users (Strassman and Qualls 1994). Growth hormone blood levels rose equally in response to all doses of DMT, and melatonin levels were unaffected. Threshold doses for significant effects relative to placebo were also hallucinogenic (0.2 mg/kg and higher). Subjects with five or more exposures to 3,4-methylenedioxymethamphetamine demonstrated less robust pupil diameter effects than those with two or fewer exposures. In another randomized, double-blind, design study of experienced hallucinogen users, tolerance to 'psychedelic' subjective effects did not occur according to either clinical interview or Hallucinogen Rating Scale scores (Strassman et al. 1996). Adrenocorticotrophic hormone (ACTH), prolactin, cortisol and heart rate responses decreased with repeated DMT administration, although blood pressure did not. The data demonstrated the unique properties of DMT relative to other hallucinogens and underscore the differential regulation of the multiple processes mediating the effects of DMT.

Other Uses

The plant is employed to prevent soil erosion and is useful in securing uninhabited sand in coastal areas. The tree's bark has limited use in tanning,

primarily for sheepskin. Leaves have been used as fish poison. The green unripe seeds were used as a substitute for soap. The flowers have fungicidal activity. The ethyl acetate fraction (500 ppm) of the ethanol flower extract showed a remarkable antifungal activity, inhibiting growth of *Rhizoctonia* sp. by 30 %, *Colletotrichum acutatum* by 15.9 % and *Fusarium oxysporum* by 10.4 % (da Silvia and Keber 2003).

Allelopathic Activity

The chloroform fraction obtained from the flower ethanol extract exhibited allelopathic activity; it inhibited markedly the germination of *Lactuca sativa* seeds and growth of the radicle and hypocotyl (Peitz and Keber 2003).

Comments

Two subspecies of *Acacia longifolia* have been recognized: *Acacia longifolia* subsp. *longifolia* and *Acacia longifolia* subsp. *sophorae* (Labill.) Court.

Bauhinia purpurea

Scientific Name

Bauhinia purpurea L.

Synonyms

Bauhinia castrata Blanco, *Bauhinia coromandeliana* DC., *Bauhinia platyphylla* Span., *Bauhinia platyphylla* Zipp ex Span., *Bauhinia purpurea* L. var. *corneri* de Wit, *Bauhinia purpurea* L. var. *violacea* de Wit, *Bauhinia rosea* Corner, *Bauhinia triandra* Roxb., *Bauhinia violacea* Corner, *Caspareopsis purpurea* (L.) Pittier, *Phanera purpurea* (L.) Benth.

Family

Fabaceae also placed in Caesalpiniaceae

Common/English Names

Hawaiian Orchid Tree, Hong Kong Orchid Tree, Pink Butterfly Tree, Purple Butterfly Tree, Purple Camel's Foot, Purple Bauhinia, Purple Orchid Tree, Semki-Gona Gum

Vernacular Names

Afrikaans: Skoenlapperorgideëboom

Origin/Distribution

The species is native to South China (which includes Hong Kong), Pakistan, India and Myanmar, southern China, Philippines and Northern Australia.

Agroecology

A tropical/subtropical species but the plant is frost hardy and light demanding. It thrives in well-drained, loamy soils in areas with 500–

2,774 mm or more annual rainfall with no dry season and with temperatures of 9–37 °C. It will survive temperatures of –4 or –5 °C. It grows from above sea level to 2,000–3000 m altitude. In its native range it occurs at lower elevations. It has escaped from cultivation and has naturalized in many tropical countries and occurs in savanna, scrub and dry deciduous forest to swamp forest evergreen lowlands, rain forest to mountain forests.

Edible Plant Parts and Uses

The leaves, flower buds, flowers and young pods are eaten as vegetable and pot herb. The flower and buds are often used in curries and pickles and as condiments (Burkill 1966). The flower buds are cooked and eaten as vegetables in Andhra Pradesh (Reddy et al. 2007) and Uttarakhand Himalaya (Namrata et al. 2011). In Thailand, young shoots and leaves are added in curry dishes; the taste is somewhat sour (Jircas 2010). The young pods and mature seeds of kachnar are known to be cooked and eaten by tribes such as the Kathkors and Gondas of India (Rajaram and Janardhanan 1991).

Botany

A shrub to small tree from 4 to 10 m high with grey to dark brown bark (Plate 1) and pubescent young aerial parts. Leaves petiolate, petiole 2.5–5 cm long, lamina 4.5–11 cm long, 4.5–10 cm wide, 9–11 nerved, cleft about halfway down into 2 acute or rounded lobes, minutely pubescent below when young (Plates 1 and 2). Inflorescence few-flowered panicles at the ends of the branches. Flowers on 5–13 mm long pedicels; tomentose, bract 3 mm long, bracteole 2 mm long, pale purple or at least purple-marked and fragrant (Plates 3 and 4). Hypanthium 7–10 mm long. Calyx 2.5–3.0 cm long, usually splitting into two reflexed segments, one emarginate the other 3 toothed. Petals 3.7–5 cm long, oblanceolate, long clawed, spreading, veined. Stamens usually 3 fertile with versatile anthers, staminodes 7. Ovary

Plate 1 Leaves and trunk of *B. purpurea*

Plate 4 Close-up of flower

Plate 2 Leaves and flower buds

Plate 3 Flowers and foliage

downy, long stalked; style long, stigma oblique. Pod 15–30 cm long by 1.5–2.5 cm broad, flat green on 2 cm long stalk and containing 12–15 seeds. Seed almost round, 1.2–1.3 cm across, brown and smooth.

Nutritive/Medicinal Properties

Flower Phytochemicals

The aqueous methanol extract of fresh flower afforded the flavonoid quercetin and flavonoid glycosides isoquercetin, astragalin, kaempferol-3-glucoside, pelargonidin-3-glucoside and 3-triglucoside (Ramchandra and Joshi 1967). The flower volatile oil was found to have monoterpenes α -terpinene, limonene, myrcene, linalool, citronellyl acetate; and a phenylpropanoid (eugenol) (Wassel et al. 1986).

Leaf Phytochemicals

The following flavonoids quercetin, rutin, quercitrin, apigenin and apigenin-7-*O*-glucoside were from the leaves (Abd-El-Wahab et al. 1987). The leaves were found to have diglucosides of quercitrin, kaempferol and isorhamnetin (Salatino et al. 1999).

A mixture of phytol fatty esters (1a, 1b, 1c, 1d, 1e, 1f), lutein, and B-sitosterol was isolated from the leaves (Ragasa et al. 2004). The two dimeric flavonoids, namely, bis [3',4'-dihydroxy-6-methoxy-7,8-furano-5',6'-monomethylalloxy]-5-C-5-biflavonyl and (4'-hydroxy-7-methyl 3-C- α -L-rhamnopyranosyl)-5-C-5-(4'-hydroxy-7-methyl-3-C- α -D-glucopyranosyl) bioflavonoid with protein-precipitating property, were isolated from 70 % aqueous acetone extract of *B. purpurea*

leaves (Yadav and Bhadoria 2005). An ursane triterpene α -amyrin caprylate was isolated along with other triterpenoids from petroleum ether fraction of ethanolic extract (95 %) of the leaf of *Bauhinia purpurea* (Verma et al. 2009).

Leaves of *B. purpurea* were found to have anti-nutrient factors: condensed tannins (195.0 mg/g) with protein-precipitating capacity (7.438 mg BSA (bovine serum albumin)/g) and protein-precipitable phenolics (64.94 %) (Yadav and Bhadoria 2001).

Stem/Bark/Wood Phytochemicals

A 6-butyl-3-hydroxyflavanone elucidated 6-(3"-oxobutyl)taxifolin and 3 glycerol derivatives 2, 3-dihydroxypropyl oleate, 2,3 dihydroxypropyl linoleate, and 2,3- dihydroxypropyl 16-hydroxy-decanoate were isolated from the heartwood (Kuo et al. 1998). A flavone glycoside 5, 6-dihydroxy-7-methoxyflavone 6-*O*- β -D-xylopyranoside was isolated from the chloroform-soluble fraction of the ethanol extract of the stem (Yadava and Tripathi 2000).

Root Phytochemicals

The dichloromethane extract of root of *B. purpurea* yielded 11 secondary metabolites comprising eight dihydrodibenzoxepins, namely, baughinoxepin C-J; a dihydrobenzofuran, baughinobenzofurin A; a novel spirochromane-2,1'-hexenedione, baughispirorin A; a new bibenzyl baughinol E; two flavanones (-)-strobopinin and demethoxymatteucinol and five known bibenzyls which possessed various pharmacological activities, namely, antimycobacterial, antimalarial, antifungal, cytotoxic and antiinflammatory activities (Boophong et al. 2007).

Seed Phytochemicals

Chalcone glycosides, butein 4'-*O*- β -L-arabinopyranosyl-*O*- β -D-galactoside (Bhartiya et al. 1981) and 3,4-dihydroxychalcone 4-*O*- β -L-

arabinopyranosyl-*O*- β -D-galactopyranoside (Bhartiya and Gupta 1981) were isolated from the seeds. *N*-hexane extract of kachnar oilseeds was found to be 17.5 % (Ramadan et al. 2006). The amount of neutral lipids in the crude *B. purpurea* seed oil was the highest (about 99 % of total lipids), followed by glycolipids and phospholipids. Linoleic followed by palmitic, oleic and stearic were the major fatty acids in the crude seed oil and its lipid classes. The oil was characterized by a relatively high amount of phytosterols β -sitosterol and stigmasterol. β -tocopherol was the major tocopherol isomer with the rest being δ -tocopherol. A flavone glycoside was isolated; glycoside-6-4'-dihydroxy-3'-prenyl-3,7,5,7'-tetramethoxy flavone-6-*O*- α -L-rhamnopyranoside was isolated from the acetone-soluble fraction of the seed ethanolic extract of *B. purpurea* (Yadav and Sodhi 2001).

The seeds of *B. purpurea* and *B. vahlii* contained higher contents of crude protein and crude lipid than those of *B. racemosa* resulting in higher energy values for these two pulses (Rajaram and Janardanan 1991). The seeds of *B. purpurea* were rich in K, whereas those of *B. racemosa* and *B. vahlii* were rich in Ca and Fe. Albumins and globulins constituted the predominant fractions of the seed proteins in *B. purpurea* and *B. vahlii*, whereas glutelins predominated in *B. racemosa*. In all three species the contents of the essential amino acids lysine, tyrosine and phenylalanine were fairly high; the contents of sulphur amino acids were limiting. Isoleucine and leucine were limiting only in *B. vahlii* proteins. Levels of anti-nutritional factors such as free phenols, tannins, L-DOPA and haemagglutinating and trypsin inhibitor activities were not particularly high.

Raw *B. purpurea* seeds were found to contain anti-nutrient factors (per 100 g): total free phenolics 2.75 g, tannins 2.35 g, phytic acid 692 mg and flatulence factors, raffinose 0.54 g, stachyose 1.17 g and verbascose 0.95 g (Vijayakumari et al. 2007). Soaking the seeds in distilled water caused maximum reduction in the phytic acid content (37 %), whereas soaking in NaHCO₃ solution reduced significant levels of phenolics and tannins (72 % and 78 %, respectively). Cooking reduced the levels of oligosaccharides (raffinose by 63 %,

stachyose by 42 % and verbascose by 79 %). Of the attempted treatments, autoclaving appeared to be most effective in reducing levels of all the investigated anti-nutrients, except phytic acid, and also improved the in-vitro protein digestibility of *B. purpurea* seeds.

Plant Phytochemicals

Four dibenz[b,f]oxepins (2a, 3–5) named bauhiniastatins 1–4 and related pacharin were isolated from the leaves, stems, pods and roots (Pettit et al. 2006).

Antioxidant Activity

Studies showed that the methanol plant extract of *Bauhinia purpurea* was more effective in scavenging free radical activity than the petroleum ether and ethyl acetate extracts in all the antioxidant tests (Shajiselvin and Muthu 2011). Maximum chelating of metal ions at 1,000 µg/ml for methanol extract was 77.56 % compared to petroleum ether extract 48.27 %, ethyl acetate extract 59.61 % and EDTA 97.90 %. The respective IC₅₀ values were 270, 1,030, 610 and 65 µg/ml for EDTA. Maximum total antioxidant activity (using the phosphomolybdic acid method) at 1,000 µg/ml for the methanol extract was 72.46 % compared to petroleum ether extract 41.61 %, ethyl acetate extract 65.70 % and ascorbate 55.23 %. The respective IC₅₀ values were 55.23, 490, 1,250 and 410 µg/ml for ascorbate. Maximum reducing ability (FRAP) at 1,000 µg/ml for the methanol extract was 77.98 % compared to petroleum ether extract 37.67 %, ethyl acetate extract 58.50 % and ascorbate 98.07 %. The respective IC₅₀ values were 290, 580, 1,430 and 50 µg/ml for ascorbate. The ethanol leaf extract (95 % v/v) exhibited significant free radical scavenging activity and reducing power activity when compared with ascorbic acid (Joshi et al. 2009). The IC₅₀ values were determined to be 78.31 and 59.37 µg/ml for the ethanol leaf extract and ascorbic acid, respectively.

The aqueous and methanol, but not chloroform, extracts of *B. purpurea* leaves (20, 100 and 500 µg/ml) exhibited concentration-dependent antioxidant activity only in the superoxide scavenging assay but low to moderate activity in the DPPH radical scavenging assay, which could be associated with their total phenolic contents (Zakaria et al. 2011b). Soxhlet-extracted (SBE), ultrasonicated (UBE) and macerated (MBE) *B. purpurea* leaf extracts exhibited good DPPH (2,2-diphenyl-1-picrylhydrazyl), ABTS (2,2-azinobis (3-ethylbenzothiazoline-6-sulfonic acid) diammonium salt) radical scavenging as well as potential reducing ability in total antioxidant capacity (TAC) and FRAP (ferric-reducing antioxidant power) methods (Annegowda et al. 2012). UBE possessed significant radical scavenging activity and reducing ability and polyphenolic constituents followed by MBE and SBE.

Anticancer Activity

Bauhiniastatins 1–4 isolated from various *B. purpurea* plant parts were found to be cancer cell growth inhibitors (Pettit et al. 2006). They exhibited significant growth inhibition against a minipanel of human cancer cell lines, and bauhiniastatin 1 was also found to inhibit the P388 (lymphocytic leukaemia) cancer cell line. Among the secondary metabolites isolated from roots, compounds bauhinoxepin C (1), bauhinoxepin D (2), bauhinoxepin F (4), bauhinoxepin H (6), bauhinoxepin I (7), bauhinoxepin J (8) and a known bibenzyl (18) exhibited cytotoxicity towards KB (nasopharyngeal carcinoma) and BC (breast cancer) cell line with IC₅₀ values ranging from 10.5 to 72.3 µM (Boopong et al. 2007). The aqueous and chloroform leaf extracts of *B. purpurea* significantly inhibited in-vitro the proliferation of all cancer cells while the methanol extract inhibited the proliferation of most cancer cells except the leukaemic CEMss cells when assessed using the 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay (Zakaria et al. 2011b). The aqueous extract was effective against human breast cancer lines MCF-7 (IC₅₀=9 µg/ml) and MDA-MB 231

(IC₅₀ = 17 µg/ml) and ovarian cancer Caov-3 (IC₅₀ = 16 µg/ml); the chloroform extract was highly effective against the CEMss (IC₅₀ = 18 µg/ml) and cervical cancer HeLa (IC₅₀ = 21 µg/ml) cell lines; and the methanol extract was highly effective only against the HL-60 (= 12 µg/ml) cell lines. All the extracts did not inhibit proliferation of 3 T3 cells suggesting their non-cytotoxic properties.

Antiinflammatory Activity

The aqueous leaf extract of *Bauhinia purpurea* exhibited antiinflammatory activity in the carrageenan-induced paw oedema in rats (Zakaria et al. 2007). The chloroform leaf extract of *B. purpurea* exhibited significant antiinflammatory activity in rats in a non-concentration-dependent manner in the carrageenan-induced paw oedema test (Zakaria et al. 2009). Unexpectedly, the 100 mg/kg extract showed a less remarkable antiinflammatory activity compared to the other doses tested. The chloroform extract of *B. purpurea* was found to contain bioactive flavonoids, saponins, triterpenes and steroids but no alkaloids and tannins. The methanol stem bark extract (300 mg/kg) exhibited antiinflammatory activity as evaluated by the carrageenan induced rat paw oedema, but its activity was lower than the standard drug, diclofenac (Chandrashekar et al. 2009b).

Among the secondary metabolites isolated from roots, compounds bauhinoxepin F (4) and bauhinoxepin I (7) possessed potent antiinflammatory activity inhibiting the COX-2 enzyme with IC₅₀ value of 6.9 and 10.1 µM, respectively (Booppong et al. 2007). Ethanol stem extract of *Bauhinia purpurea* displayed significant antiinflammatory activity as determined by carrageenan-induced paw oedema using plethysmometer in albino rats (Shreedhara et al. 2009). Ethanol root extract of *B. purpurea* administered to rats at doses of 200, 400 mg/kg body weight produced significant antiinflammatory activity in the carrageenan-induced paw oedema model and cotton pellet granuloma pouch method (Pais et al. 2012).

Nephroprotective Activity

Studies showed that the ethanol extract of leaves and unripe pods of *B. purpurea* possessed potent nephroprotective activity against gentamicin-induced toxicity in rats (Lakshmi et al. 2009). Gentamicin-induced glomerular congestion, blood vessel congestion, epithelial desquamation, accumulation of inflammatory cells and necrosis of the kidney cells were found to be reduced in the groups receiving the leaf and unripe pods extract of *Bauhinia purpurea* along with gentamicin. The extracts also normalized the gentamicin-induced increase in serum creatinine, serum uric acid and blood urea nitrogen levels. This was also confirmed by the histopathological studies.

Anti-hypothyroidism Activity

Studies showed that daily administration of *B. purpurea* bark extract (2.5 mg/kg body wt.) to female mice for 20 days increased serum triiodothyronine (T3) and thyroxine (T4) concentrations (Panda and Kar 1999). The extract elicited an increase in hepatic glucose-6-phosphatase (G-6-Pase) activity and antiperoxidative effects as indicated either by a decrease in hepatic lipid peroxidation (LPO) and/or by an increase in the activity of antioxidant enzyme. The results suggested that the plant extract was capable of stimulating thyroid function in female mice.

Recent studies found that *B. purpurea* plant extract has the potential to ameliorate metformin-induced hypothyroidism in type 2 diabetic animals (Jatwa and Kar 2009). The researchers reported that dexamethasone (1.0 mg/kg, i.m.) administration caused hyperglycaemia with a parallel increase in renal lipid peroxidation (LPO), relative risk ratio (RR) and the concentrations of serum insulin, total cholesterol (TC), low-density lipoprotein cholesterol (LDL-C), very low density lipoprotein cholesterol (VLDL-C) and triglycerides (TG). Dexamethasone decreased serum triiodothyronine, thyroxine and high-density lipoprotein cholesterol (HDL-C) levels as well as renal superoxide dismutase (SOD), catalase (CAT) and reduced glutathione (GSH) content. Oral administration

with metformin (150 mg/kg) to dexamethasone-induced diabetic animals reduced renal lipid peroxidation (LPO), relative risk ratio, serum concentrations of insulin, glucose and low-density lipoprotein cholesterol (LDL-C) with a parallel increase in cellular antioxidants, but it further reduced circulating thyroxine level and caused severe hypothyroidism. Oral administration with either *Withania somnifera* (1.4 g/kg) or *Bauhinia purpurea* (2.5 mg/kg) extract along with dexamethasone and metformin elevated the concentrations of circulating triiodothyronine and thyroxine to euthyroid level. The plant extracts also corrected relative risk ratio and serum lipid concentration.

Antimicrobial Activity

The mixture of phytol fatty esters, siltated from the leaves, was found to have low activity against the fungi *Aspergillus niger* and *Candida albicans* and inactive against the bacteria *Psuedomonas aeruginosa*, *Staphylococcus aureus*, *Bacillus subtilis* and *Escherichia coli* and the fungus, *Trichophyton mentagrophytes* (Ragasa et al. 2004). The isolated secondary metabolites, isolated from roots, exhibited antimycobacterial activity with MIC values ranging from 24.4 to 740.7 μ M. Among all compounds bauhinoxepin J was the most potent antimycobacterial agent having a MIC value of 24.4 μ M (Boophong et al. 2007).

Among the secondary metabolites isolated from roots, compounds bauhinoxepin C (1), bauhinoxepin F (4), bauhinobenzofurin A (9), 2 known bibenzyls (15) and (18) exhibited antifungal activity (IC_{50} 49.6–130.1 μ M) (Boophong et al. 2007). Soxhlet-extracted (SBE), ultrasonicated (UBE) and macerated (MBE) *B. purpurea* leaf extracts exhibited antibacterial activity, with UBE inhibiting most of the bacteria followed by MBE and SBE (Annegowda et al. 2012).

Antiulcerogenic Activity

Oral administration of the aqueous leaf extract of *B. purpurea* to rats was found to have

antiulcerogenic activity in a dose-dependent manner (Zakaria et al. 2011a). The extract at the dose of 5,000 mg/kg did not cause any signs of toxicity to rats. Histological studies supported the observed antiulcer activity of the extract. Further the extract increased gastric wall mucus secretion. The results supported the traditional uses of *Bauhinia purpurea* in the treatment of ulcers.

CNS (Central Nervous System) Activity

The aqueous leaf extract of *Bauhinia purpurea* exhibited antinociceptive activity in mice in the abdominal constriction, hot plate and formalin tests (Zakaria et al. 2007). The chloroform leaf extract of *B. purpurea* was found to possess significant, but concentration-independent, antinociceptive activity in mice when assessed using the abdominal constriction and hot-plate test (Zakaria et al. 2009). Ethanol root extract of *B. purpurea* administered to rats at doses of 200, 400 mg/kg body weight exhibited antinociceptive activity in the tail flick and acetic acid-induced writhing tests (Pais et al. 2012). Ethanol stem extract of *Bauhinia purpurea* exhibited significant analgesic activity as evaluated by the Eddy's hot-plate and acetic acid writhing animal models (Shreedhara et al. 2009). The ethyl acetate stem bark extract (400 mg/kg) exhibited analgesic activity as tested by acetic acid-induced writhing model and hot plate method (Chandrashekar et al. 2009a).

Hepatoprotective Activity

Studies showed that the aqueous, alcoholic and chloroform leaf extracts of *B. purpurea* exhibited hepatoprotective effects against carbon tetrachloride-induced hepatotoxicity in albino Wistar rats (Veena Rani et al. 2011). All the extracts dose-dependently lowered the elevated levels of alkaline phosphatase (ALP), serum glutamic pyruvic transaminase (SGPT) serum glutamic oxaloacetic transaminase (SGOT), total protein (TP), acid phosphatase (AP) total bilirubin (TB) and direct bilirubin (DB) induced

by carbon tetrachloride. This was confirmed by histopathological studies. The hepatoprotective activity of the extract was ascribed to its good antioxidant activity. In another study, the results of in-vivo experiments showed that the water bark extract of *B. purpurea* inhibited lipid peroxidation, protected the experimental animals from alcohol-induced hepatic toxicity in rats and maintained the levels of antioxidants in a dose-dependent manner (Chaturvedi et al. 2011). Both methanol and water bark extracts scavenged free radicals equivalent to gallic acid scavenging and were found rich in total phenol content.

Wound Healing Activity

In the excision and burn wound models, rats treated with high doses of methanol and chloroform leaf extracts of *Bauhinia purpurea* showed significant reduction in time taken for epithelialization and wound contraction (50 %) compared to control (Ananth et al. 2010). A significant increase in breaking strength was found in incision wound model with methanol and chloroform extracts compared to their respective carbopol and simple ointment bases. In the dead space wound model, methanol and chloroform extract treatment (100 and 500 mg/kg) orally produced a significant increase in the breaking strength, dry tissue weight and hydroxyproline content of the granulation tissue when compared to control. Among the extracts, methanol extract exhibited more activity followed by the chloroform extract. The study indicated that *Bauhinia purpurea* leaves exhibited wound healing activity.

Antidiabetic Activity

The ethanol stem extract of *B. purpurea* and its fraction-I exhibited antidiabetic activity in alloxan-induced diabetic rats, as evident from the serum glucose levels (Muralikrishna et al. 2008). The hypoglycaemic activity may be ascribed to the presence of flavonoids. Oral treatment of the ethanol flower leaf and root extracts of *B. purpurea* at

doses of 100, 200, 400 mg/kg for 15 days exhibited significant antidiabetic activity in streptozotocin-induced diabetic rats by reducing and normalizing the elevated fasting blood glucose levels as compared to those of streptozotocin control group (Prasanna and Shastry 2012).

Cardiotonic Activity

The F1 fraction of the ethanol stem extract of *B. purpurea* exhibited excellent adrenergic activity (10 mg/ml) in isolated frog's heart (Muralikrishna et al. 2008). This was further confirmed as its action was blocked by an adrenergic β_2 -blocker (propranolol) in isolated frog heart. The cardiotonic activity exhibited by the fraction-I was probably due the presence of flavonoids. The results suggested that the fraction-I exhibited positive inotropic and chronotropic effect on an isolated frog's heart.

Antipyretic Activity

The aqueous leaf extract of *Bauhinia purpurea* exhibited antipyretic activity in rats in the brewer's yeast-induced pyrexia test (Zakaria et al. 2007).

Anti-diarrhoeal Activity

The ethanol leaf extract of *B. purpurea* exhibited significant anti-diarrhoeal activity in two animal models, viz. castor oil-induced diarrhoea in rats and gastrointestinal motility test by using charcoal meal compared to the control group (Mukherjee et al. 1998).

Antimalarial Activity

Among the secondary metabolites isolated from roots, compounds bauhinoxepin H, bauhinoxepin I, bauhinoxepin J and a known bibenzyl exhibited antimalarial activity with IC_{50} values 5.8–11.2 μ M (Boophong et al. 2007).

Immunological Activity

Bauhinia purpurea lectin (BPA), a galactose- and lactose-binding lectin, was found to have nine amino acids and the amino acid sequence: aspartic acid, threonine, tryptophan, proline, asparagine, threonine, glutamic acid, tryptophan and serine (Yamamoto et al. 1991). Studies showed that a chimeric lectin with unique carbohydrate-binding specificities could be formed *Bauhinia purpurea* lectin (BPA) and *Lens culinaris* lectin (LCA) (Yamamoto et al. 2000). The chimeric lectin can be constructed from BPA by substituting several amino acid residues in its metal-binding region with other amino acid residues from LCA, providing a powerful tool for biochemical, immunochemical and histochemical studies. *Bauhinia purpurea* agglutinin (BPA) a Galbeta1-3GalNAc (T)-specific leguminous lectin had been widely used in multifarious cytochemical and immunological studies of cells and tissues under pathological or malignant conditions (Wu et al. 2004). This lectin possessed a binding specificity to dense cell surface Galbeta1-3GalNAc (T), high-density polyvalent GalNAcalpha1-Ser/Thr (Tn) and Galbeta1-3/4GlcNAc (I/II) glycoconjugates facilitating its future use in biotechnological and medical applications.

Anthelmintic Activity

The aqueous and ethanol *B. purpurea* plant extracts exhibited significant anthelmintic activity at highest concentration of 100 mg/ml against *Pheretima posthuma* (Kumar et al. 2011).

Traditional Medicinal Uses

The bark, root, leaves and flowers of *Bauhinia purpurea* are reputed to have medicinal properties and used in traditional folk medicine in India, Pakistan, Sri Lanka and Malaysia (CSIR 1948; Chopra et al. 1956; Burkill 1966). Flowers are laxative and are used as a purgative in Pakistan, while the leaves are applied externally to the forehead to treat fever. The leaves contain tannin and

are used for poulticing sores and boils in Malaysia and India. The dried buds are used in the treatment of piles, dysentery, diarrhoea and worms. In India the bark is used for poulticing treatment of skin diseases, scrofula and ulcers stomach tumour and wounds. A decoction of the bark is taken for diarrhoea. The root is used as an antidote to snake poison and decoction of the root used for dyspepsia.

In Sarawak, Malaysia, the Ibans consume a tea made from the roots for high blood pressure, stomachache and diarrhoea (Chai 2006). Pounded leaves are rubbed on the back to alleviate backache. The Kayan take the root decoction for cough, stomachache and diarrhoea and the solution used as gargle for toothache. The Kedayan boiled the root with fennel and shallot and drink the decoction for stomach-ache and diarrhoea. The Penan drink the root decoction for toothache. The Selako boil the leaves with sea weed and sea shells and drink the decoction to relieve kidney problems and pain when urinating.

B. purpurea have been used to treat stomach tumours, ulcers, wounds, glandular swellings, diarrhoea and fever in traditional medicine (Zakaria et al. 2007). *B. purpurea* known to the Malays as 'pokok tapak kerbau' has been traditionally used by the Indian, Sri Lankan and Pakistani people to treat ailment like ulcer, wound, glandular swelling and stomach tumour. The decoction of the root is used for expelling gases, flatulence and griping pain from the stomach and bowel; the bark of the plant is used as an astringent in the treatment of diarrhoea. Its decoctions are recommended as a useful wash solution for ulcers. Decoction of *B. purpurea* stem administered twice a day as folk remedy was found to be effective against asthma and other respiratory disorders (Patil et al. 2008) The bark or root and flower mixture with boiled rice water is used as maturant for boils and abscesses (Kurian 2004). The decoction of flower is used as a laxative (Wassel et al. 1986). Fresh bark of Kaanchanaara (*B. purpurea*) mixed with Shunthi (dry *Zingiber officinale*), pounded with sour gruel, was prescribed in enlarge cervical glands (Vrindamaadhava) as well as in goitre (Shaarangadhara Samhitaa, Bhavaprakaasha). Over the counter Kaanchanaara

(*B. purpurea*) Guggulu (Shaarangadhar Samhita) is used to treat enlarge cervical glands, goitre and scrofulous tumours. The roots are used as carminative and flower buds as laxative and anthelmintic in folkloric medicine in Mangalore, India (Shiddamallayya et al. 2010). Bark sap with honey is taken against leucorrhoea and is also used to treat menstrual problems in Assam (Das et al. 2008).

Other Uses

The plant is often cultivated as an ornamental, roadside, garden plant and shade tree. It is also used for soil improvement and erosion control. The leaves, pods and shoots are used as fodder. The stem yields semki-gona gum and the bark is good as tanning material, dyeing and for fibre. The wood is used for making furniture, agricultural implement and for house building and fuel.

Comments

Bauhinia purpurea can be grown from seeds, stem cuttings or by air layering.

Bauhinia variegata

Scientific Name

Bauhinia variegata L.

Synonyms

Bauhinia candida Ait., *Bauhinia chinensis* (DC.) Vogel, *Bauhinia decora* Uribe, *Bauhinia variegata* var. *alboflava* de Wit, *Bauhinia variegata* L. var. *candida* (Aiton) Corner, *Bauhinia variegata* L. var. *chinensis* DC., *Phanera variegata* (L.) Benth.

Family

Fabaceae, also placed in Caesalpiniaceae

Common /English Names

Bauhinia, Butterfly Ash, Butterfly Tree, Camel's Foot, Camel's Foot Tree, Mountain Ebony, Orchid Tree, Pink Orchid Tree, Poor Man's Orchid, Purple Orchid Tree, Variegated Orchid Tree, White Bauhinia, White Bauhinia Orchid Tree, White Camel's Foot, White Variegated Orchid Tree

Vernacular Names

Origin/Distribution

The plant is indigenous to southern China, the Indian sub-continent (i.e. Bhutan, India, Nepal and Pakistan) and Southeast Asia (i.e. Laos, Myanmar, Vietnam and Thailand). It is now widely cultivated elsewhere in subtropical and tropical regions of the world. It has naturalized elsewhere in the tropics in Queensland and southern United States.

Agroecology

It grows in areas that annually receive between 750 and 2,000 mm of rainfall with temperatures ranging from 21 to 35 °C. The species grows well in soils of medium fertility that are neither droughty nor wet; it is not tolerant of nutrient-poor sites found throughout India, ascending to an attitude of 1,300 m in the Himalayas.

Edible Plant Parts and Uses

Young sour leaves are eaten as a side dish with rice; flowers and flower buds are also reported eaten in India, Southeast Asia, Africa and South America (Facciola, Burkill).

Botany

A small, erect, medium-sized evergreen or deciduous to semi-deciduous tree that reaches 2–8 m in height and up to 20 cm in trunk diameter. The leaves are alternate, variable in size, ranging from 5 to 13 cm across, bilobed less than halfway, cordate base with 5–12 palmate veins and borne on 2–4 cm long petioles (Plates 1, 2, 3, and 4). Flowers 1 or few, in short lateral racemes, showy,

Plate 1 Alternate, bilobed leaves

Plate 4 Close view of light purple flower

Plate 2 A white flower variety

Plate 3 Bud and open flowers

large and fragrant; petals obovate, 3–8 cm long, 2–3 cm wide, variable in colour, either pale purple to rose or white, the uppermost one darker, with purple or crimson veins or blotches, or white

to yellowish, with green veins, and purplish externally, fertile stamens 5, the anthers 5 mm long; staminodes 5 (Plates 2, 3 and 4). Pods long, narrow and pointed at the ends, hard, flat, glabrous, 13–25 cm long, 15–18 mm wide, coiled upon dehiscence to become falcate containing 10–15 seeds. Seeds light brown, rounded, flat, 15–16 mm long by 11–13 mm wide.

Nutritive/Medicinal Properties

Flower Phytochemicals

The flavonoids kaempferol, kaempferol-3-galactoside and kaempferol-3-rhamnoside were isolated from the ethanol extract of white flowers (Rahman and Begum 1966).

Seed Phytochemicals

B. variegata seed was found to have the following amino acid profile: linolenic acid 0.55 %, linoleic acid 36.84 %, oleic acid 26.14 %, stearic acid 16.95 %, palmitic acid 19.52 % and myristic acid traces (Zaka et al. 1983). The residual meal after the extraction of oil contained 41 % protein. *Bauhinia variegata* seed oil was found to have the following physicochemical characteristics (Arain et al. 2012): refractive index (40 °C) 1.4589, peroxide value 1.9 meq O₂/kg oil, iodine value 84.5 g I₂/100 g of oil, saponification number

191.3 mg KOH/g oil, free fatty acids 0.6 %, and unsaponifiable matter 0.9 %. The fatty acid profile comprised linoleic acid C18:2 (42.1 %), oleic acid C18:1 cis 9 (13.4 %), stearic acid C18:0 (17.5 %) and palmitic acid C16:0 (22.11 %) as the major fatty acids. Minor amounts of palmitoleic acid C16:1 (0.4 %), oleic acid cis 7 (0.5 %), margaric acid C17:0 (0.3 %), linolenic acid C18:3 n-6 (0.5 %), arachidic acid C20:0 (1.3 %), behenic acid C22:0 (0.5 %), eicosapentaenoic acid C20:5 (0.2 %) and nervonic acid C24:1 (0.6 %) were also detected. Defatted seed residue contained 41.9 % protein, 18 % oil, 4.8 % ash, 6.7 % moisture, 6.9 % fibre and 28.4 % total carbohydrate. The seed was found to have a high protein content of 29.41 % and lipid content of 14.89 (Pinto et al. 2005).

A flavone glycoside, 5-hydroxy-7,3',4',5'-tetra-methoxyflavone 5-*O*- β -D-xylopyranosyl-(1 \rightarrow 2)- α -L-rhamnopyranoside, was isolated from the seeds (Yadava and Reddy 2001). A galactose-binding lectin (BvcL) was isolated from *B. variegata* candida seeds (Silva et al. 2007). It consisted of a large content of serine, glycine, threonine, aspartic acid and glutamic acid and low concentrations of methionine, cysteine and histidine. The N-terminal amino acid sequence of 17 residues showed 90 % sequential homology to galactose-specific legume lectins of the subfamily Caesalpinioideae. They found that the haemagglutination activity of BvcL was not specific for any human blood group trypsin-treated erythrocytes. A dimeric 64-kDa melibiose-binding lectin was isolated from the seeds (Lin and Ng 2008). A galactose-specific lectin, named BVL, was purified from seeds; it had a pattern similar to other lectins isolated from the same genus, *Bauhinia purpurea* agglutinin (BPA) (Pinto et al. 2008).

Trypsin inhibitors were isolated from seeds of two *Bauhinia variegata* varieties namely *Bauhinia variegata* candida trypsin inhibitor (BvcTI) and *B. variegata* lilac trypsin inhibitor (BvlTI) with molecular weights of about 20,000 without free sulfhydryl groups (Di Ciero et al. 1998). Amino acid analysis revealed a high content of aspartic acid, glutamic acid, serine and

glycine and a low content of histidine, tyrosine, methionine and lysine in both inhibitors. Three isoforms were detected in both types. Trypsin inhibitor isoform 3 (BvcTI-3) was composed of 167 residues with a calculated molecular mass of 18,529. Homology studies with other trypsin inhibitors showed that BvcTI-3 belonged to the Kunitz family.

Leaf and Non-woody Aerial Parts Phytochemicals

Physiochemical studies revealed that the leaves had 9.42 % total ash, 5.72 % acid-insoluble ash and water-soluble extractive value of 3.30 % and loss on drying at 105 °C was 6.27 % (Modh et al. 2011). The following flavonoids, quercetin, rutin, quercitrin, apigenin and apigenin-7-*O*-glucoside were isolated from the leaves (Abd-El-Wahab et al. 1987). Preliminary phytochemical analysis revealed the presence of alkaloid, tannin, flavonoid, steroid, triterpenoid and saponin in different extracts. HPTLC fingerprinting for flavonoids revealed presence of two flavonoids rutin and kaempferol. Two long-chain compounds, heptatriacontan-12,13-diol and dotetracont-15-en-9-ol, were isolated from the leaves (Singh et al. 2006). A new triterpene saponin, named as 23-hydroxy-3 α -[*O*- α -L-1C4-rhamnopyranosyl-(1'' \rightarrow 4')-*O*- α -L-4C1-arabinopyranosyl-oxy]olean-12-en-28-oic acid *O*- α -L-1C4-rhamnopyranosyl-(1''' \rightarrow 4''')-*O*- β -D-4C1-glucopyranosyl-(1''' \rightarrow 6''')-*O*- β -D-4C1-glucopyranosyl ester, plus six flavonoid compounds along with two cinnamic acid derivatives were isolated from the leaves (Mohamed et al. 2009).

Six flavonoids, namely, kaempferol (1), ombuin(2),kaempferol7,4'-dimethylether3-*O*- β -D-glucopyranoside (3), kaempferol 3-*O*- β -D-glucopyranoside (4), isorhamnetin 3-*O*- β -D-glucopyranoside (5) and hesperidin (6), together with one triterpene caffeate, 3 β -*trans*-(3,4-dihydroxycinnamoyloxy)olean-12-en-28-oic acid (7), were isolated from the nonwoody aerial parts (Rao et al. 2008).

Stem Phytochemicals

Hentriacontane, octacosanol, β -sitosterol and stigmasterol (Prakash and Khosa 1976) were isolated from the stem bark. 5,7-Dihydroxy flavonone-4'-*O*- α -L-rhamnopyranosyl- β -D-glucopyranosides (Gupta et al. 1979), β -sitosterol, lupeol and naringenin 5,7-dimethyl ether 4'-rhamnoglucoside were isolated from the stem (Gupta et al. 1980). A phenanthraquinone, named bauginione isolated from *Bauhinia variegata* stem was elucidated as 2,7-dimethoxy-3-methyl-9,10-dihydrophenanthrene-1,4-dione (Zhao et al. 2005). Rhamnocitrin, a flavonoid, and other compounds 4-*O*- β -D-glucosylbenzoic acid, 5,3'-dihydroxy-6,7,4'-trimethoxyflavanone and 2,4,8,9,10-pentahydroxy-3,7-dimethoxy-anthracene-6-*O*- α -L-rhamnopyranoside were isolated from the stem bark (Surendra et al. 2012).

Root Phytochemicals

A flavonol glycoside 5,7,3',4'-tetrahydroxy-3-methoxy-7-*O*- α -L-rhamnopyranosyl (1 \rightarrow 3)-*O*- β -galactopyranoside was isolated from the roots (Yadava and Reddy 2003). A flavanone, 5,7-dimethoxy-30,40-methylenedioxyflavanone, and a dihydrodibenzoxepin, 5,6-dihydro-1,7-dihydroxy-3,4-dimethoxy-methyldibenz oxepin were isolated from the roots (Reddy et al. 2003).

Recent studies reported that *B. variegata* possess chemopreventive, antitumour, cytotoxic, hepatoprotective, antibacterial and antiinflammatory activities.

Antioxidant Activity

The ethanol leaf extract of *Bauhinia variegata* exhibited significant in-vitro antioxidant activity with IC_{50} value of 38.5 μ g/ml for DPPH radical scavenging activity, IC_{50} of 70 μ g/ml for nitro oxide radical and IC_{50} of 48.5 μ g/ml for hydroxyl radical (Saraswathy et al. 2011). The level of oxidation products like lipid peroxides and hydroperoxides decreased significantly in leaf extract

incubated neutrophils. Likewise, the antioxidants like reduced glutathione (GSH), catalase and superoxide dismutase (SOD) levels were increased significantly in leaf extract incubated neutrophils when compared to activated neutrophils. The methanol bark extract of *B. variegata* and its polar fractions n-butanol, ethyl acetate and remaining extract showed greater in-vitro DPPH and reducing power antioxidant activity (EC_{50} 44.07, 58.09, 69.68 and 51.81 μ g/ml, respectively) in comparison to non-polar fractions (hexane and chloroform) (Sharma et al. 2011a). However, all the fractions effectively protected pBR322 plasmid DNA from hydrogen peroxide-induced damage.

The methanol leaf, bark and flower of *Bauhinia variegata* were found to have hydroxyl radical scavenging activity (Pandey et al. 2012). All the extracts exhibited different level of in-vitro antioxidant activity which was concentration dependent. The percent inhibition (TBARS—thiobarbituric acid reactive substance) at concentration of 10–30 μ g/ml was 20.86–62.58 % for the leaf extract, 19.42–60.07 % for the stem extract, 21.58–65.46 % for the bud extract and for ascorbic acid (reference standard) 25.89–70.50 %. Methanol extract was found to be good solvent for extraction and in having good antioxidant activity. The antioxidant IC_{50} values for leaf, stem bark and floral buds were 17.9, 19.5 and 17.2 μ g/ml respectively.

Anticancer Activity

Treatment of ethanol *B. variegata* (EBV) extract to Dalton's ascitic lymphoma-bearing Swiss albino mice, enhanced mean survival time with respect to the untreated tumour-bearing mice (Raj Kapoor et al. 2003b). The treatment also enhanced peritoneal cell counts. After 14 days of inoculation, EBV was able to reverse the changes in the haematological parameters, protein and PCV caused by the tumour. Similarly they found that oral administration of EBV was effective in reducing solid tumour mass development induced

by Ehrlich ascites carcinoma (EAC) cells in Swiss albino mice (Raj Kapoor et al. 2003c). Further, studies using animal models showed that ethanol extract of *Bauhinia variegata* exhibited significant chemopreventive and cytotoxic effect against *N*-nitrosodiethylamine (DEN)-induced liver tumour and human cancer cell lines (Raj Kapoor et al. 2006). Oral administration of ethanol extract of *Bauhinia variegata* (EBV) (250 mg/kg) effectively suppressed liver tumour induced by DEN as revealed by decrease in DEN induced elevated levels of serum glutamate pyruvate transaminase (SGPT), serum glutamate oxaloacetate transaminase (SGOT), alkaline phosphatase (ALP), total bilirubin, gamma glutamate transpeptidase (GGTP), lipid peroxidase (LPO), glutathione peroxidase (GPx) and glutathione S-transferase (GST). The extract produced an increase in enzymatic antioxidant (superoxide dismutase and catalase) levels and total proteins when compared to those in liver tumour-bearing rats. The histopathological changes of liver samples were compared with respective controls. EBV was found to be cytotoxic against human epithelial larynx cancer (HEp2) and human breast cancer (HBL-100) cells. The dimeric melibiose-binding lectin from the seeds inhibited proliferation in hepatoma HepG2 cells and breast cancer MCF7 cells with an IC_{50} of 1.4 μ M and 0.18 μ M, respectively (Lin and Ng 2008).

A significant reduction of skin papilloma, with delayed appearance and reduction in the cumulative number of papillomas was observed in the DMBA (7,12-dimethylbenz[α]anthracene) +Kachanar (*Bauhinia variegata* bark extract) +croton oil-treated mice as compared to the DMBA+croton oil-treated mice (Agrawal and Pandey 2009; Pandey and Agrawal 2009). C57 bl mice which received a 50 % methanol extract of Kachanar extract at the doses of 500 and 1,000 mg/ kg body weight for 30 days showed increase in life span and significant reduction in tumour size as compared to controls. In another study they showed that the methanol flower extract had a chemopreventive role against DMBA-induced skin carcinogenesis in mice (Pandey and Agrawal 2010a).

Antimutagenic Activity

In antimutagenicity studies, a single application of Kachanar (*Bauhinia variegata* bark) extract at doses of 300, 600 and 900 mg/kg dry weight, 24 hours prior to the i.p. administration of cyclophosphamide (at 50 mg/kg), significantly prevented micronucleus formation and chromosomal aberrations in bone marrow cells of mice in a dose-dependent manner (Agrawal and Pandey 2009; Pandey and Agrawal 2010b).

Antimicrobial Activity

The alcoholic extract of *B. variegata* was found to have antimicrobial activity against *Bacillus subtilis*, *Pseudomonas aeruginosa*, *Salmonella typhi*, *Shigella dysenteriae*, *Staphylococcus aureus* and *Vibrio cholera* (Pokhrel et al. 2002). The most sensitive bacterium was *B. subtilis* and the minimum bactericidal concentration (MBC) of the crude extract for this bacterium was 0.39 mg/ml. The extract was found to be more effective against Gram-positive than Gram-negative bacteria.

The antibacterial activity of defatted extracts of *Bauhinia variegata* bark powder was higher than those without defatting (Parekh et al. 2006). Maximum activity was observed at highest concentration i.e. 10 mg/ml. Defatted acetone and methanol extracts of *Bauhinia variegata* were most active as compared to other extracts against all the studied microorganisms – Gram-positive bacteria (*Bacillus cereus* and *Staphylococcus aureus*) and Gram-negative bacteria (*Klebsiella pneumoniae*, *Escherichia coli*, and *Pseudomonas pseudoalcaligenes*). Petroleum ether extracts were inactive against all microorganisms. Ethanol stem bark extract of *B. variegata* exhibited antimicrobial activity at concentration range of 50–300 μ g/ml in a concentration-dependent manner against *Staphylococcus aureus*, *Bacillus subtilis*, *Pseudomonas aeruginosa*, *Escherichia coli*, *Candida albicans* and *Aspergillus niger* (Mali et al. 2008).

The ethanol leaf extract of *Bauhinia variegata* showed maximum inhibitory activity against

Salmonella typhi, followed by *Vibrio cholera*, *Klebsiella pneumonia*, *Escherichia coli* and *Staphylococcus aureus* (Gunalan et al. 2011). For fungi, the leaf extract was very effective against dermatophyte, *Trichophyton mentagrophytes* and against the plant pathogen *Mucor hiemalis*. The alcoholic leaf extract of leaves of *Bauhinia variegata* showed higher antimicrobial activity against Gram-positive species *Staphylococcus aureus* and *Bacillus subtilis* and Gram-negative species *Escherichia coli* and *Pseudomonas aeruginosa* than the petroleum ether and chloroform extracts (Dhale 2011). Phytochemical analysis indicated the presence of alkaloids, oil, fat glycoside, carbohydrates, phenolics, tannins, lignin, saponins, flavonoids and terpenoids in the leaf and bark extracts.

Antidiabetic Activity

The leaves of *Bauhinia variegata* were found to have insulin-like proteins (Azevedo et al. 2006). The activity of this insulin-like protein (0.48 mg/ml) on serum glucose levels of four-week-old Swiss albino (CF1) diabetic mice was similar to that of commercial swine insulin used as control. Further characterization of this molecule by reverse-phase hydrophobic HPLC chromatographic analysis as well as its antidiabetic activity on alloxan-induced mice showed that it has insulin-like properties. This finding supported the use of the plant as anti-diabetic agent in traditional Brazilian medicine. Studies showed that administration of the stem bark extract for 7 days suppressed the elevated blood glucose levels in alloxan-induced hyperglycaemic rats (Kumar et al. 2012). The antihyperglycaemic effect of the extract was comparable to metformin. It was found that the bark extract (200 and 400 mg/kg) and metformin did not influence blood glucose in normal rats.

The crude ethanol leaf extract and its major metabolite (6 S,7 E,9 R)-9-hydroxymegastigma-4,7-dien-3-one-9- β -glucopyranoside (roseoside) exhibited insulinotropic activity (Frankish et al. 2010). The crude extracts and the major metabolite were found to enhance insulin release from the beta-cell lines INS-1 in a dose-dependent manner.

Antiinflammatory Activity

A flavonol glycoside 5,7,3',4'-tetrahydroxy-3-methoxy-7-*O*- α -L-rhamnopyranosyl(1 \rightarrow 3)-*O*- β -galactopyranoside isolated from the roots showed antiinflammatory activity (Yadava and Reddy 2003). Six flavonoids, namely kaempferol (1), ombuin (2), kaempferol 7,4'-dimethyl ether 3-*O*- β -D-glucopyranoside (3), kaempferol 3-*O*- β -D-glucopyranoside (4), isorhamnetin 3-*O*- β -D-glucopyranoside (5) and hesperidin (6), together with one triterpene caffeate, 3 β -*trans*-(3,4-dihydroxycinnamoyloxy)olean-12-en-28-oic acid (7) isolated from the nonwoody aerial parts significantly and dose-dependently inhibited lipopolysaccharide (LPS) and interferon (IFN)-gamma-induced nitric oxide (NO) and cytokines [tumour necrosis factor (TNF)-alpha and interleukin (IL)-12] (Rao et al. 2008). The concentration causing a 50 % inhibition (IC₅₀) of NO, TNF-alpha and IL-12 production by compounds 1, 2 and 7 was approximately 30, 50 and 10 μ M, respectively, while at 50, 200 and 40 μ M compounds 3, 4 and 5, 6 showed 15–30 % inhibition, respectively. In contrast, compounds 3 and 7 showed no inhibitory effect, while compounds 1, 4–6 reduced by around 10–30 % the synthesis of NO by macrophages, when inducible NO synthase was already expressed with LPS/IFN-gamma for 24 hours. The findings supported the use of the plant for management of inflammatory conditions.

A triterpene saponin, isolated from the leaves, named as 23-hydroxy-3 α -[*O*- α -L-1C4-rhamnopyranosyl-(1'' \rightarrow 4')-*O*- α -L-4C1-arabinopyranosyl-oxy]olean-12-en-28-oic acid *O*- α -L-1C4-rhamnopyranosyl-(1''' \rightarrow 4''')-*O*- β -D-4C1-glucopyranosyl-(1''' \rightarrow 6''')-*O*- β -D-4C1-glucopyranosyl ester was found to be nontoxic (LD₅₀) and to have significant antiinflammatory and antinociceptive activities (Mohamed et al. 2009). It also showed slight antischistosomal activity.

Effect of ethanol stem extract of *Bauhinia variegata* exhibited antiarthritic activity on complete Freund's adjuvant (CFA)-induced arthritis in rat (Raj Kapoor et al. 2007). Oral administration of the extract effectively inhibited rat paw oedema volume. The extract significantly lowered the

elevated levels of serum aspartate transaminase (AST), alanine aminotransferase (ALT) and alkaline phosphatase (ALP) induced by arthritis. The extract also altered the increase in superoxide dismutase (SOD), glutathione peroxidase and decreased catalase level in liver and kidney observed in adjuvant-induced arthritis and normalized the antioxidant levels.

Hepatoprotective Activity

Alcoholic stem bark extract (SBE) at different doses (100 and 200 mg/kg) administered orally to male Sprague-Dawley rats intoxicated by carbon tetrachloride exerted significant hepatoprotective activity (Bodakhe and Ram 2007). A new phenanthraquinone, named bauhinione, 2,7-dimethoxy-3-methyl-9,10-dihydrophenanthrene-1,4-dione was isolated from the stem. Similarly, Sahu et al. (2011) found that oral administration of an ethanol leaf extract to Wistar albino rats intoxicated by paracetamol had a hepatoprotective effect. The leaf extract elicited a significant reduction in level of serum glutamic oxaloacetic transaminase (53.26 %), serum glutamic pyruvic transaminase (41.64 %), serum alkaline phosphatase (72.30 %) and bilirubin (68.18 %) and prevented liver histopathological changes in rats induced by paracetamol.

Nephroprotective Activity

Administration of *B. variegata* ethanol stem extract at dose levels of 400 and 200 mg/kg (bw) to cisplatin-intoxicated rats for 14 days attenuated the biochemical and histological signs of nephrotoxicity of cisplatin in a dose-dependent fashion (Pani et al. 2011). Ethanol extract at 400 mg/kg decreased the serum level of creatinine and urea associated with a significant increase in body weight and urine volume output as compared to the toxic control group. The ethanol stem extract of *B. variegata* at 400 mg/kg (bw) exhibited significant and comparable nephroprotective potential to that of the standard

polyherbal drug, cystone. In another study, both extracts ethanol and aqueous root extracts of *B. variegata* exerted significant nephroprotective activity in gentamicin-induced nephrotoxic rats as evident by decrease in elevated serum creatinine, serum urea, urine creatinine and blood urea nitrogen levels, which was further substantiated by histopathological study (Sharma et al. 2011b). In gentamicin-induced glomerular congestion, blood vessel congestion and epithelial desquamation, accumulation of inflammatory cells and necrosis of the kidney cells were found to be reduced in the groups receiving the root extract with gentamicin. Both extracts exhibited significant DPPH, nitric oxide and superoxide radical scavenging activity.

Antihyperlipidaemic Activity

Studies showed that alcoholic and aqueous extracts of *B. variegata* stem and roots could effectively decrease plasma cholesterol, triglyceride, LDL and VLDL and increase plasma HDL levels in Triton WR-1339 (iso-octyl polyoxyethylene phenol)-induced hyperlipidaemic albino rats (Rajani and Ashok 2009). Further, the alcoholic and aqueous extracts exhibited significant antioxidant activity in scavenging DPPH, superoxide, nitric oxide and hydrogen peroxide radicals and reducing power. Its antihyperlipidaemic activity may be attributed to its antioxidant activity.

Immunomodulatory Activity

Different fractions of *B. variegata* seed proteins (albumin, globulin, prolamins, acid glutelin and alkaline glutelin) demonstrated haemagglutinating activity against native and enzyme-treated rabbit erythrocytes with the globulin fraction showing the highest specific haemagglutinating activity (Pinto et al. 2005). Acid glutelin and albumin exhibited higher specific haemagglutinating activity against trypsin-treated and papain-treated rabbit erythrocytes, respectively.

On oral administration, the ethanol stem bark extract of *Bauhinia variegata* elicited a significant increase in the primary and secondary humoral antibody responses, by increasing the haemagglutinating antibody titre at doses of 250 and 500 mg/kg/p.o, in mice (Ghaisas et al. 2009). There was a significant increase in the phagocytic index and percentage neutrophil adhesion at doses of 250 and 500 mg/kg/p.o. The study suggested that the ethanol extract of the stem bark of *Bauhinia variegata* Linn may have promise as an immunomodulatory agent, acting probably by stimulating both the specific and nonspecific arms of immunity. In another study, pretreatment with aqueous and ethanol bark extracts caused dose-dependent and significant reduction in the total leucocyte and eosinophil counts in albino mice with milk-induced leukocytosis and eosinophilia (Mali and Dhake 2011). The results suggested that *Bauhinia variegata* possessed antieosinophilic activity.

Haematinic Activity

The ethanol stem bark extract of *Bauhinia variegata* exerted a haematinic activity on haemolytic anaemic rats (Dhonde et al. 2007).

Antiulcerogenic Activity

Oral administration of alcoholic extract of *B. variegata* to rats with ulcers induced by pyloric ligation and aspirin, decreased the volume of gastric secretion, total, free acidity and ulcer index with respect to control (Raj Kapoor et al. 2003a). The alcoholic extract of *B. variegata* exhibited significant ulcer protective activity.

Anticataract Activity

In ovine and chick embryo lens model, rhamnocitrin isolated from the stem bark showed significant protection against cloudiness in lenses induced by hydrogen peroxide and hydrocortisone in a dose-dependent manner (Surendra et al. 2012). The findings suggested rhamnocitrin pos-

sessed significant anticataract activity which was most likely due to its antioxidant property.

Antiviral Activity

The dimeric melibiose-binding lectin from the seeds inhibited HIV-1 reverse transcriptase activity with an IC₅₀ of 1.02 µM.

Mitogenic Activity

The dimeric melibiose-binding lectin from the seeds and concanavalin A (Con A) evoked maximal mitogenic response from mouse splenocytes at similar concentrations, but the maximal response to *B. variegata* lectin was only 1/5 of that induced by Con A in magnitude (Lin and Ng 2008).

Anthelmintic Activity

Ethanol stem bark extract of *B. variegata* exhibited anthelmintic activity in dose-dependent manner, giving shortest time of paralysis and death at 100 mg/ml concentration, for *Pheretima posthuma* and *Ascaridia galli* worms (Mali et al. 2008).

Traditional Medicinal Uses

Various parts of the tree have been used in local folk medicine for various ailments in Nepal, India, Sri Lanka and Malaysia especially in the Ayurveda medicine system (CSIR 1959; Chopra et al. 1956; Burkill 1966; Kapoor and Kapoor 1980; Mali et al. 2007; Kumar et al. 2012; Sahu and Gupta 2012). In Sri Lanka, the plant is used for diarrhoea, dropsy, renal problems, dyspepsia, fistula, glandular enlargement, leprosy, piles, skin diseases and for slimming. Different parts of the plant have been used to suppress the oedema, dysentery, ulcers, eye disease, skin diseases, piles and haemorrhoids. Kachnar is widely used in Ayurveda as tonic to the liver (Bodakhe and Ram 2007). The plant juice is used in bath after

childbirth. The bark is alterative, anthelmintic, astringent and tonic. In Nepal, the juice of the bark is used in the treatment of amoebic dysentery, diarrhoea and other stomach disorders. Powdered bark is traditionally used for tonic, strains, ulcers and skin diseases. A paste of the bark is useful in the treatment of cuts and wounds, skin diseases, scrofula and ulcers.

The root is used as an antidote to snake poison and a root decoction is used to treat dyspepsia (Yadava and Reddy 2003; Agrawal and Pandey 2009). The flowers and dried flower buds are used in the treatment of piles, dysentery, diarrhoea, intestinal worms and stomach disorders and as a laxative (Malhotra and Moorty 1973; Badhe and Pandey 1990).

Other Uses

It is a very popular ornamental tree in landscaping and as a hedge plant in subtropical and tropical regions, grown for its showy fragrant flowers and unusual bilobed leaves. The bark is used for dyeing. The wood is used for the production of furniture and agricultural implements.

Comments

Distinct differences between *B. variegata* and *B. purpurea* occur in stamen number and the following characters:

B. purpurea. Flower buds 4 or 5 angled or winged; petals pale purple, shading to pinkish proximally, oblanceolate, 3–6 cm long, not more than 2 cm broad; fertile stamens 3; staminodes 7; leaf blades elliptic to suborbicular, 6–19 cm long and broad, rounded to cordate at base, lobed 1/2–1/4 their length, the lobes rounded to acute.

B. variegata. Flower buds not angled or winged; petals pale purple or rose or white or yellow, obovate 4–6 cm long, 2–3 cm broad, the uppermost one broader; fertile stamens 5; staminodes 5, about half as long as stamens; leaf blades broadly ovate to suborbicular, 5–14 cm long and broad, cordate to truncate at base, lobed about 1/3 their length or less, the lobes rounded.

Caesalpinia pulcherrima

Scientific Name

Caesalpinia pulcherrima (L.) Sw.

Synonyms

Caesalpinia pulcherrima var. *flava* Bailey and Rehder, *Poinciana bijuga* Lour., *Poinciana elata* Lour., *Poinciana pulcherrima* L.

Family

Fabaceae also in Caesalpinaceae

Common/English Names

Barbados Flower-Fence, Barbados Pride, Barbados-Pride, Bird-Of-Paradise Flower, Dwarf Poinciana, Flower Crest, Flower-Fence, Flowerfence, Paradise Flower, Paradise-Flower, Peacock Flower, Peacock Tree, Poinciana, Poincillade, Pride of Barbados, Pride-Of-Barbados, Red Bird of Paradise, Spanish Carnation

Vernacular Names

Thailand: Khwaang Yoi (Eastern), Som Pho (Northern), Haang Nok Yuung Tai, Nok Yung Tai (Central)

Ulithian: Warapig

Vietnam: Diep Ta, Diep Cung, Kim Phuw Owng

to semi-drought conditions and tolerate extreme heat. It grows in a wide range of well-drained soils, from alkaline to acidic. It is moderately tolerant of saline conditions and is frost sensitive.

Edible Plant Parts and Uses

The flowers and young pods and seeds are eaten (Tanaka 1976; Pongpangan and Poobrasert 1985; Facciola 1990). Green seeds are sweetish and eaten raw in Thailand or cooked.

Botany

An erect, smooth much-branched shrub or small tree, 1.5–6 m high, branches unarmed or with a few straight prickles. The leaves are alternate, paripinnate, rachis 10–40 cm long, with 5–9 pairs of pinnae, stipules subulate, minute, caducous, leaflets opposite (Plates 1, 2 and 3), apetiolate, 6–12 pairs per pinnae, base unequal, rounded, apex rounded to retuse. Inflorescence in axillary and terminal raceme or panicle, 20–50 cm long; flowers bisexual, red, reddish-pink, orange, orangey-yellow, orange, bright yellow or creamy white; sepals 10–15 × 5–7 mm; petals crisped and clawed, 10–25 × 6–8 mm; stamens very long and very far exserted; ovary with 8–12 ovules (Plates 1, 2, 3, 4, 5 and 6). The pod is nearly straight, flat, smooth, 6–12 cm by 1.5–2 cm wide with 6–8 rectangular, brown or black seeds.

Plate 1 Reddish-pink flowers, young pods and pinnate leaves

Origin/Distribution

The plant is a native of the West Indies and Mexico and Central America. It is widely distributed and naturalized in the tropics.

Agroecology

A tropical tree species, adapted to temperatures of 15–35 °C in full sun to partial shade, from sea level to 1,000 m altitude or higher but is adapted

Plate 2 Close view of reddish-pink flowers

Plate 3 Orange-yellow flowers, pods and leaves

Plate 4 Orange and orange-yellow flowers with long exserted stamens

Plate 5 Bright yellow flowers, pods and leaves

bohydrates 39.1 %, 18.3 %; crude lipid 6.6 %, 5.65 %; crude fibre 9.06 %, 5.98 %; crude protein 48.08 %, 42.97 %; energy 312.15 kcal/100 g, 217.47 kcal/100 g; mineral composition per 100 g : Na 49.5 mg, 40.5 mg; K 39.5 mg, 31 mg; Ca 37.5 mg, 30.5 mg; Mg 58.5 mg, 69.5 mg; Fe 21 mg, 15 mg; P 56 mg, 124 mg; respectively. The results of another analysis conducted in Nigeria (Omole 2003) revealed that the crude protein and crude fat of the seeds were 33.50 and 16.80 %, respectively. The fatty acid profile indicated that the glycerides of oleic, linoleic and linolenic acid accounted for 82.46 % of the total glycerides. Iodine value and saponification number were 104.09 and 195.0, respectively, while the unsaponifiable matter showed a high value of 20 %.

Various scientific studies reported that *Caesalpinia pulcherrima* had antiviral, antiinflammatory, antitumorous, antiulcerogenic and antimicrobial properties.

Nutritive/Medicinal Properties

Analyses carried out in Nigeria (Yusuf et al. 2007) on the proximate composition of whole seeds and seed nuts (dehulled and dried) are % dry weight basis: moisture 9.5 %, 7.3 %; dry matter 90.95 %, 92.7 %; ash 4.5 %, 6.22 %; car-

Plate 6 Creamy-white flowers

Antiviral Activity

One study showed that aqueous extracts of *C. pulcherrima* and its related quercetin possessed a broad-spectrum antiviral activity against herpes viruses (HSV-1, HSV-2) and adenoviruses (ADV-3, ADV-8, ADV-11). Among them, the strongest activities against adenovirus ADV-8 were fruit and seed ($EC_{50}=41.2$ mg/l, $SI=83.2$), stem and leaf ($EC_{50}=61.8$ mg/l, $SI=52.1$) and flower ($EC_{50}=177.9$ mg/l, $SI=15.5$), whereas quercetin possessed the strongest anti-ADV-3 activity ($EC_{50}=24.3$ mg/l, $SI=20.4$). In conclusion, some compounds of *C. pulcherrima* which possess antiviral activities may be derived from the flavonoid of quercetin. The mode of action of quercetin against HSV-1 and ADV-3 was found to be at the early stage of multiplication and with SI values greater than 20, suggesting the potential use of this compound for treatment of the infection caused by these two viruses.

Antiinflammatory Activity

The following homoisoflavonoids, (*E*)-7-methoxy-3-(4'-methoxybenzylidene) chroman-4-one and (*E*)-7-hydroxy-3-(3',4',5'-trimethoxybenzylidene) chroman-4-one, (*Z*)-7-hydroxy-3-(4'-methoxybenzylidene) chroman-4-one (isobonducellin), (*E*)-7-hydroxy-3-(4'-methoxybenzylidene) chroman-4-one (bonducellin) and (*E*)-7-hydroxy-3-(2',4'-dimethoxybenzylidene) chroman-4-one, were isolated from the whole plant of *Caesalpinia pulcherrima*. Five flavonoids, namely, 5,7-dimethoxyflavanone (1), 5,7-dimethoxy-3',4'-methylenedioxyflavanone (2), isobonducellin (3), 2'-hydroxy-2,3,4',6'-tetramethoxychalcone (4) and bonducellin (5), exhibited significant antiinflammatory activity. They significantly and dose-dependently inhibited the inflammatory mediators: nitric oxide (NO) and cytokines [tumour necrosis factor (TNF)-alpha and interleukin (IL)-12]. According to their inhibitory results, the order of antiinflammatory potency was compounds $3>5>4>2>1$. Furthermore, peritoneal macrophages were pre-activated with lipopolysaccharide LPS/IFN-gamma (interferon-gamma) for 24 hours and determined the inhibitory effects of the above-mentioned isolates on the production of NO after a further 24 hours. The findings supported the use of *Caesalpinia pulcherrima* for the treatment of inflammatory diseases in traditional medicine. Two new flavonoids, 5,7-dimethoxy-3',4'-methylenedioxyflavanone and isobonducellin along with 2'-hydroxy-2,3,4',6'-tetramethoxychalcone, 5,7-dimethoxyflavone and bonducellin, were isolated from the aerial parts of *Caesalpinia pulcherrima*. Both flavonoids also exhibited antimicrobial activity.

Antimicrobial Activity

A new cassane-type diterpene isovouacapenol E (1) was isolated from the leaves of *Caesalpinia pulcherrima*, together with the known compounds caesaldekalin A (3), spathulenol (4), caryophyllene oxide (5), phytol and sitosterol. Four new cassane-type furanoditerpenoids (1–4) were isolated from the air-dried leaves of

Caesalpinia pulcherrima. The exocyclic methylene compound 1 readily isomerized and oxidized to the benzofuran 4. Benzyl 2, 6-dimethoxybenzoate (5) was also identified in this study. Antimicrobial tests on 1–5 indicated that they were active against several bacteria (*Staphylococcus aureus*, *Escherichia coli*, *Pseudomonas aeruginosa* and *Bacillus subtilis*) and fungi (*Candida albicans* and *Trichophyton mentagrophytes*). An ethanolic extract of the dry fruits of *Caesalpinia pulcherrima* exhibited a broad spectrum of antimicrobial activity, particularly against *Escherichia coli* (enteropathogen), *Proteus vulgaris*, *Pseudomonas aeruginosa* and *Staphylococcus aureus*.

Antitumorous Activity

Cassane diterpenoids: pulcherralin, pulcherrin A, pulcherrin B, pulcherrin C, neocaesalpin P, neocaesalpin Q and neocaesalpin R, together with eight known compounds: isovouacapenol C, 6-*p*-cinnamoyl-7 β -hydroxy-vouacapen-5 α -ol, pulcherrimin E, pulcherrimin C, α -cadinol, 7-hydroxycadalene, teucladiol and bonducellin—were isolated from the stem of *Caesalpinia pulcherrima*. Five new cassane diterpenoids (1–5) were isolated from the roots of *Caesalpinia pulcherrima*, along with the known isovouacapenol C (6), pulcherrimin A (11) and 6 β -cinnamoyl-7 β -hydroxyvouacapen-5 α -ol (12). Two cassane-furanoditerpenoids, 6 β -benzoyl-7 β -hydroxyvouacapen-5 α -ol (1) and 6 β -cinnamoyl-7 β -hydroxyvouacapen-5 α -ol (2), expressed moderate cytotoxic activity towards KB (human oral carcinoid cancer), BC (human breast cancer) and NCI-H187 (small cell lung cancer) cell lines. Compound 2 showed strong antitubercular activity with a minimum inhibitory concentration (MIC) of 6.25 μ g/ml, whereas the benzoyl analogue (1) was less active (MIC 25 μ g/ml).

Antilcerogenic Activity

Caesalpinia pulcherrima also has antiulcerogenic property. Pretreatment of the petroleum ether

extract of *Caesalpinia pulcherrima* prevented the formation of gastric lesions in HCl/ethanol model in rats. In the aspirin and pylorus ligation model, the extract was able to significantly reduce the ulcer score and increased mucus content, but had no effect on gastric juice volume or acid content. Thus the results indicated that the extracts' antiulcerogenic effect was attributable to augmentation of gastric defence mechanisms.

Traditional Medicinal Uses

The bark, leaves, flowers, fruits and roots serve medicinal purposes in folkloric medicine. In general a decoction or infusion of roots, bark, leaves or flowers is used as a purgative and emmenagogue. Bark, root and flower have been used in traditional medicines for cutaneous and subcutaneous parasitic infection, febrifuges, pulmonary troubles; leaf especially for nasopharyngeal affections and as laxatives; and leaf and flower as abortifacients and ecbolics. Wood, leaf, root, flower and seed-pod provide tannins and astringents and seeds provide mucilage.

Medicine men in the Amazon Rainforest have long known some of the medicinal uses for *Caesalpinia pulcherrima*, which is known as *ayoowiri*. The juice from the leaves is said to cure fever, the juice from the flower is said to cure sores, and the seeds are said to cure bad cough, breathing difficulty and chest pain. Roots are used as abortifacient. In Papua New Guinea, the roots are used as an abortifacient, whereas the leaves are taken to relieve constipation. In Vietnam, the roots are used as an emmenagogue in folk medicine. In Indonesia, the pounded roots are given to children for convulsions, the bark employed for diarrhoea. The leaves are used with acorn and onions and applied to distended stomach. The leaves are also purgative and used as abortifacient to bring on abortion and used for fever infusion in Indochina. In the West Indies, the leaves and flowers are taken for fever. The flowers are reputed to have purgative, febrifuge and emmenagogue properties. A decoction is a popular remedy for erysipelas and for inflammation of the eyes. They are used also as a tonic.

The flowers are used as vermifuge and a decoction for coughs and chronic catarrh. The fruit is astringent and is employed against diarrhoea and dysentery. The seeds are used as an effective abortifacient.

Other Uses

Peacock flower is a popular ornamental throughout the tropics. It is commonly used for living fences, hedge plant and windbreaks in tropical countries. The flowers, in powder, are used as insecticides. The plant has been used as fish poison. By-products from the leaves include dyes, tannin, stains, inks, tattoos and mordants. The seeds contain galactomannans which can be used as food stabilizers. The firm heartwood serves the production of wooden pegs or tree nails. A yellow-flowering race of this species is used by the Chinese in Malaysia for ritual purposes. It is also the national flower of the Caribbean island of Barbados and is depicted on the Queen's personal Barbadian flag.

Comments

The plant is readily propagated from seeds or stem cuttings.

Clitoria ternatea

Scientific Name

Clitoria ternatea L.

Synonyms

Clitoria albiflora Mattei, *Clitoria bracteata* Poir., *Clitoria coelestris* Siebert & Voss, *Clitoria parviflora* Raf., *Clitoria philippensis* Perr., *Clitoria pilosula* Benth., *Clitoria ternatea* var. *pilosula* (Benth.) Baker, *Clitoria ternatensium* Crantz, *Lathyrus spectabilis* Forssk., *Nauchea ternatea* (L.) Descourt., *Ternatea ternatea* (L.) Kuntze, *Ternatea vulgaris* Kunth, *Ternatea vulgaris* Kuntze

Family

Fabaceae, also in Papilionaceae

Common/English Names

Asian Pigeonwing, Blue Butterfly Pea, Blue Pea, Butterfly Pea, Butterfly Pea Flower, Cordofan-Pea, Cocos

Vernacular Names

Arabic: Mazariyune-Hindi, Bazrulmazariyune-Hindi (Seeds), Bazrulmazariyunchindi, Buzrula, Mazariyunchindi

Chinese: Die Dou

Brazil: Cunha, Clitória

French: Honte, Pois Tonelle

Origin/Distribution

The true origin of the species is obscured by extensive naturalization; it is probable that it originated from South America. It is now distributed pantropically.

Agroecology

The plant grows wild in wasteland, thickets or disturbed areas and on most soil types at low and medium altitudes. It is adaptable to a wide range of soil types from sandy soils to heavy clays including calcareous soils and with a wide pH range from 4.5 to 8.9. It is moderately tolerant to salinity. It thrives in areas with 700–1,500 mm mean annual rainfall but will survive in areas with only 400 mm and dry periods. It tolerates short-term flooding but not prolonged waterlogging. It is tolerant to light frost and will tolerate low temperatures down to 15 °C and high temperature to 35 °C. It prefers full sun but will tolerate partial shading and is used as cover crops in rubber and coconut plantations in the tropics.

Edible Plant Parts and Uses

The flower, fruit and leaves are edible (Burkill 1966; Tanaka 1976; Facciola 1990; Kaisoon et al. 2001; Wetwitayaklung et al. 2008). In Southeast Asia, the flowers are used for colouring rice in puddings and cakes and leaves used for colouring food stuff green. In Thailand, the leaves are used in salad and for frying. Young pods are edible and eaten as vegetable.

Botany

A short-lived, fast-growing climbing perennial, leguminous herb. Stem thin, glabrous or sparsely pubescent, climbing or twining, 2–5 m long. Leaves imparipinnate, arranged in 2–3 pairs, bright green, petiolate (1.5–3 cm long), leaflets elliptic-ovate to elliptic lanceolate, 1.5–5 cm by 0.4–3 cm wide, acute or notched apex and rounded base, margin entire (Plates 1 and 2). Inflorescence axillary bearing several flowers on 4–9 mm long pedicels and with ovate, persistent bracteoles. Flowers—clitoris-like flower shape with large obovate, reflexed, funnel-shaped standard, 5 cm long, light to deep blue, mauve or white and yellow at the inner base (Plates 1 and 2). Pods flattish, linear-oblong, 6–12 cm long by 0.6–1.2 cm wide, beaked with 4–8 flat, rounded, olive-brown to black seeds.

Plate 1 Blue flowers and imparipinnate leaves

Nutritive/Medicinal Properties

Phytochemicals in Flowers

The per cent yield and the amount of total polyphenols in g/100 g calculated as gallic acid on dried flowers and crude methanol extracts basis of *C. ternatea* extract were reported as 10.23 %, 0.55 g dried flower, 2.29 g crude extract (Wetwitayaklung et al. 2008). Among 24 edible flowers tested, the lowest TEAC value was obtained from the extract of *Clitoria ternatea* (TEAC=0.01, IC₅₀=1.08 mg/50 µl) and *Sesbania grandiflora* (TEAC=0.01, IC₅₀=1.32 mg/50 µl) (Wetwitayaklung et al. 2008).

Clitoria ternatea flowers were found to contain little calcium (1.9 mg/100 g) compared to common vegetables as determined *via* inductively coupled

Plate 2 Close view of flower

plasma atomic emission spectroscopy (Chin 1992). The soluble phenol acids (per g dry weight) identified in *Clitoria ternatea* flower extract were as follows: gallic acid 33.2 µg, protocatechuic acid 1.8 µg, caffeic acid 10.03 µg, *p*-coumaric acid 11.6 µg, ferulic acid 34.8 µg, sinapic acid 152.8 µg and total phenolic acid 243.5 µg (Kaisoon et al. 2001). The flowers contained 261.5 µg total bound phenolic acid made up of ferulic acid 108 µg and sinapic acid 153.5 µg. The flowers contained 115.5 µg total soluble flavonoid made up of rutin 38.1 µg, myricetin 4.85 µg, quercetin 68.9 µg and kaempferol 3.65 µg; and bound flavonoid 141.4 µg made up of quercetin 113.2 µg, quercetin 11.1 µg and apigenin 17.2 µg. The DPPH radical scavenging activity (% inhibition) of soluble and bound phenolic fraction of the flower was 32.7 and 17.59 %, respectively. The reducing potential of the soluble and bound phenolic fraction of the flower as evaluated by FRAP (ferric-reducing antioxidant power) assay mmol FeSO₄/100 g dry weight was 16.37 mmol and 7.7 mmol, respectively. Bound phenolics exhibited lower antioxidant activity than soluble ones.

The anthocyanins, malvidin-3-β-glycoside and delphinidin-3-β-glycoside were isolated from *C. ternatea* flowers (Srivastava and Pandey 1977). Saito et al. (1985) found that stability of the anthocyanins increased with the degree of acylation with cinnamic and malonic acids as well as with the degree of substitution of hydrogens on the B ring in *C. ternatea*. Other anthocyanins reported were ternatins, polyacetylated delphinidin 3,3',5'-triglucosides that conferred blue colour to the petals *C. ternatea*. Six new stable anthocyanins, named ternatin A1, A2, B1, B2, D1 and D2, were isolated from the blue flowers of *Clitoria ternatea* (Terahara et al. 1989a). The structures of two common components prepared from alkaline deacylation of ternatin mixture yielded two common components: *E*-4-*p*-coumaryl β-D-glucoside (1) and delphinidin 3,3',5'-tri-β-D-glucoside (2). The structure of ternatin A1 was elucidated as 3-*O*-(6-*O*-malonyl-β-D-glucopyranosyl)-3',5'-di-*O*-(6-*O*-(*E*-4-*O*-(6-*O*-(*E*-4-*O*-β-D-glucopyranosyl-*p*-coumaryl)-β-D-glucopyranosyl)-*p*-coumaryl)-β-

D-glucopyranosyl)-delphinidin (Terahara et al. 1990c). Ternatin D1, an acylated anthocyanin, was elucidated as 3-*O*-(6-*O*-malonyl-β-D-glucopyranosyl)-3',5'-di-*O*-(6-*O*-(*E*-4-*O*-(6-*O*-*E*-*p*-coumaryl-β-D-glucopyranosyl)-*p*-coumaryl)-β-D-glucopyranosyl)delphinidin (Terahara et al. 1989b); ternatin A1, the largest ternatin (Terahara et al. 1990b); ternatin B1, a pentaacylated anthocyanin elucidated as 3-*O*-(6-*O*-malonyl-β-D-glucopyranosyl)-3'-*O*-β-D-glucopyranosyl-*E*-*p*-coumaryl-β-D-glucopyranosyl-*E*-*p*-coumaryl-β-D-glucopyranosyl-β-D-glucopyranosyl-5'-*O*-*E*-*p*-coumaryl-β-D-glucopyranosyl-*E*-*p*-coumaryl-β-D-glucopyranosyl β-D-glucopyranosyl-delphinidin (Kondo et al. 1990). Two acyl moieties, prepared by alkaline deacylation or H₂O₂ oxidation of ternatin mixture from *C. ternatea* flowers, were identified as *E*-4-*O*-β-D-glucopyranosyl-*p*-coumaric acid and 6-*O*-malonyl-D-glucopyranose and six ternatins A1, A2, B1, B2, D1 from the flowers were partly characterized as highly acylated delphinidin derivatives (Terahara et al. 1990a). Deacylternatin was determined as delphinidin 3,3',5'-tri-*O*-β-D-glucopyranoside (Terahara et al. 1990b). The structure of ternatin A2 was identified as 3-*O*-(6-*O*-malonyl-β-D-glucopyranosyl)-3'-*O*-(6-*O*-(*E*-4-*O*-(6-*O*-(*E*-4-*O*-β-D-glucopyranosyl-*p*-coumaryl)-β-D-glucopyranosyl)-*p*-coumaryl)-β-D-glucopyranosyl)-5'-*O*-(6-*O*-(*E*-4-*O*-β-D-glucopyranosyl-*p*-coumaryl)-β-D-glucopyranosyl)delphinidin (Terahara et al. 1990d). Anthocyanins ternatins A1, A2, B1, B2, D1 and D2 were isolated from double blue flowers (Honda et al. 1991). Five anthocyanins, namely, ternatins A3, B4, B3, B2 and D2, were isolated from *Clitoria ternatea* flowers (Terahara et al. 1996). Eight new anthocyanins 1–8 (ternatins C1, C2, C3, C4, C5 and D3 and preternatins A3 and C4) were isolated from *Clitoria ternatea* flowers (Terahara et al. 1998). The structures of 1–6 were postulated as delphinidin 3-malonylglucoside having 3'-GCGC-5'-G, 3'-GCGCG-5'-G, 3'-GC-5'-G, 3'-GCG-5'-G, 3'-G-5'-G and 3'-GC-5'-GC, and compounds 7 and 8 as delphinidin 3-glucoside having 3'-GCG-5'-GCG and 3'-GCG-5'-G as side chains, respectively, in which Dp=delphinidin, G=D-glucose and C=*p*-coumaric acid.

The following flavonol glycosides were isolated from the petals of *Clitoria ternatea* cv Double Blue: kaempferol 3-*O*-(2''-*O*- α -rhamnosyl-6''-*O*-malonyl)- β -glucoside; quercetin 3-*O*-(2''-*O*- α -rhamnosyl-6''-*O*-malonyl)- β -glucoside; myricetin 3-*O*-(2'',6''-di-*O*- α -rhamnosyl)- β -glucoside; kaempferol 3-(2(G)-rhamnosylrutinoside); quercetin 3-(2(G)-rhamnosylrutinoside); kaempferol 3-neohesperidoside; quercetin 3-neohesperidoside; myricetin 3-neohesperidoside; kaempferol 3-rutinoside; quercetin 3-rutinoside; myricetin 3-rutinoside; kaempferol 3-glucoside; quercetin 3-glucoside; myricetin 3-glucoside; and myricetin 3-*O*-(2''-*O*- α -rhamnosyl-6''-*O*-malonyl)- β -glucoside (Kazuma et al. 2003b). Delphinidin 3-*O*-(2''-*O*- α -rhamnosyl-6''-*O*-malonyl)- β -glucoside; 2, delphinidin 3-*O*-(6''-*O*-malonyl)- β -glucoside; 3, delphinidin 3-neohesperidoside; and 4, delphinidin 3-*O*- β -glucoside were isolated from the petals of a mauve line (WM) (Kazuma et al. 2003a). Ternatins, a group of 15 (poly)acylated delphinidin glucosides, were identified in all the blue petal lines (WB, BM-1, 'Double Blue' and 'Albiflora'), WM accumulated delphinidin 3-*O*-(6''-*O*-malonyl)- β -glucoside instead. The white petal line (WW) did not contain anthocyanins. The change in flower colour from blue to mauve was not due to a change in the structure of an anthocyanidin from delphinidin but to the lack of (polyacylated) glucosyl group substitutions at both the 3'- and 5'-positions of ternatins implying glucosylation at the 3'- and 5'-positions of anthocyanin to be a critical step in producing blue petals in *C. ternatea*. Among the ternatins, blue anthocyanins found in the petals of *Clitoria ternatea*, ternatin C5 (delphinidin 3-*O*-(6''-*O*-malonyl)- β -glucoside-3',5'-di-*O*- β -glucoside) was found to have the structure common to all the ternatins, i.e. characterized by its glucosylation pattern: a 3,3',5'-triglucosylated anthocyanidin (Kazuma et al. 2004). An intermediate in the biosynthesis of ternatin C5 in the blue petals, delphinidin 3-*O*-(6''-*O*-malonyl)- β -glucoside-3'-*O*- β -glucoside, was also identified. In *C. ternatea*, a blue flower cultivars (DB) and mauve flower variety (WM) accumulated polyacylated anthocyanins (ternatins) and delphinidin 3-*O*-(6''-*O*-

malonyl)- β -glucoside (Kogawa et al. 2007b). Further, WM accumulated minor delphinidin glycosides—3-*O*- β -glucoside, 3-*O*-(2''-*O*- α -rhamnosyl)- β -glucoside and 3-*O*-(2''-*O*- α -rhamnosyl-6''-*O*-malonyl)- β -glucoside of delphinidin. These glycosidic patterns for minor anthocyanins in WM were also found among the minor flavonol glycosides in all the varieties including a white flower variety (WW) although the major flavonol glycosides were 3-*O*-(2''-*O*- α -rhamnosyl)- β -glucoside, 3-*O*-(6''-*O*- α -rhamnosyl)- β -glucoside, 3-*O*-(2'',6''-di-*O*- α -rhamnosyl)- β -glucoside of kaempferol, quercetin and myricetin. A UDP-glucose: anthocyanin 3',5'-*O*-glucosyltransferase (UA3'5'GT) was purified from the petals of *Clitoria ternatea* which accumulated polyacylated anthocyanins named ternatins (Kogawa et al. 2007a). In the biosynthesis of ternatins, delphinidin 3-*O*-(6''-*O*-malonyl)- β -glucoside (1) was first converted to delphinidin 3-*O*-(6''-*O*-malonyl)- β -glucoside-3'-*O*- β -glucoside (2). Then 2 was converted to ternatin C5 (3), which was delphinidin 3-*O*-(6''-*O*-malonyl)- β -glucoside-3',5'-di-*O*- β -glucoside. UA3'5'GT was responsible for these two steps by transferring two glucosyl groups in a stepwise manner. Its substrate specificity revealed the regioselectivity to the anthocyanin's 3'- or 5'-OH groups. The presence of alkaloids, flavonoids, saponins, tannins, carbohydrates and proteins were reported in the methanol extract of the flowers (Uma et al. 2009).

Phytochemicals in Seeds

Sinha (1960a) identified yellow fixed oil (yield 18.78 %) from the seeds and isolated γ -sitosterol. Gupta and Lal (1968) reported hexaconazole, β -sitosterol and an anthoxanthin glucoside from the seeds; on acid hydrolysis, the anthoxanthin glucoside yielded quercetin and glucose. They also identified the following amino acids in the seed: lysine, valine, methionine, phenylalanine, isoleucine, aspartic acid, serine, glycine, alanine, glutamic acid, tyrosine, proline, arginine and histidine. Kulshrestha and Khare (1968) isolated six crystalline compounds in the seeds: adenosine,

kaempferol-3-rhamnoglucoside, *p*-hydroxycinnamic acid and ethyl- α -D-GALACTOPYRANOSIDE, and two remaining compounds a polypeptide and a phenylglycoside.

Clitoria ternatea seed was found to contain 1.75 % moisture, 10.2 % oil, 38.4 % protein, 44.8 % total sugars, 3.75 % ash and energy 500.5 cal/100 g (Joshi et al. 1981). The seed oil was found to contain palmitic, stearic, oleic, linoleic and linolenic acids in the weight ratio of 18.5, 9.5, 51.4, 16.8 and 3.8 %, respectively. The oil had a specific gravity of 0.884 at 30 °C, refractive index at 39 °C of 1.459, saponification value of 187.7, iodine value of 70.4, acid value of 0.25 and unsaponifiable matter of 1.8 %. Protein constituted 38.4 % comprising 18 amino acids. Essential amino acid profile was (%) lysine (6.40–6.55), histidine (2.03–2.15), threonine (3.13–3.2), phenylalanine (3.2–3.30), methionine (1.06–1.04), serine (6.7–6.86), tyrosine (2.05–2.17), cystine (0–0.11), arginine (7.13–7.16), glutamic acid (23.9–24.03), aspartic acid (12.5–12.7), alanine (4.6–6.8), valine (5.8), proline traces, γ -aminobutyric acid traces and leucine plus isoleucine (15.51–15.8).

The seeds were found to contain 4.79 % oligosaccharides (Revilleza et al. 1990).

Three trypsin inhibitors were isolated from the seeds (Macedo and Xavier-Filho 1992). *C. ternatea* seeds were found to contain antifungal proteins, homologous to plant defensins (Osborn et al. 1995). Low levels of condensed tannins (0–2.48 mg catechin/g) and protein precipitable polyphenols (0.16–0.77 mg tannic acid/g) were detected in the raw mature seeds (Laurena et al. 1994).

Finotin a small basic antimicrobial and insecticidal protein was isolated from the seeds (Kelemu et al. 2004). A β -D-galactoside-specific lectin, designated *C. ternatea* agglutinin (CTA), purified from *Clitoria ternatea* seeds was found to compose of two identical subunits of molecular weight 34.7 kDa associated by non-covalent bonds and belonged to Gal/Gal NAc-specific group (Naeem et al. 2007a, b). CTA agglutinated trypsin-treated human B erythrocytes and may probably exhibit sugar uptake activity. This lectin

could be used as valuable tool for glycobiology studies in biomedical and cancer research since it binds β -D-galactosides. The content of lectin was found to be 30 mg/30 g dry weight of pulse. The yield was 2.8 % as compared to 0.3 % obtained on fetuin column.

Phytochemicals in Leaves

Leaf mucilage was reported to contain anhydrogalactose, anhydropentosan and methyl pentosan (Sinha 1960b). Aiyar et al. (1973) reported 3 glycosides of kaempferol from the leaves: kaempferol-3-monoglucoside, kaempferol-3-rhamnosyl (1 \rightarrow 6) glucoside and kaempferol-3-rhamnosyl (1 \rightarrow 6) galactoside. The light petroleum ether and ether extracts yielded waxy material, chlorophyll and β -sisterol. Four kaempferol glycosides, I, II, III and IV, were isolated from *Clitoria ternatea* leaves and identified as kaempferol 3-glucoside (I), 3-rutinoside (II) and 3-neohesperidoside (III) and IV was characterized as kaempferol-3-*O*-rhamnosyl-(1 \rightarrow 2)-*O*-[rhamnosyl-(1 \rightarrow 6)]-glucoside and named clitorin (Morita et al. 1977). Stigmast-4-ene-3,6-dione was isolated from the dried leaves of *C. ternatea* (Ripperger 1978). The leaves were reported to have 12.5 % moisture content, 13.2 % total ash, 4.8 % acid insoluble ash, 5.3 % water soluble ash, water soluble extractive value 25.2 % and alcohol soluble extractive value 18.4 % (Taur et al. 2010).

Phytochemicals in Aerial Parts

Phytoconstituents such as propane 1,1-diethoxy- (4.73 %), 1,6,10-dodecatriene, 7,11-dimethyl-3-methylene-, (*Z*)- (1.18 %), 1,2,3,5-cyclohexanetetrol (1 α ,2 α ,3 α ,5 α)- (3.55 %), myo-inositol, 4-C-methyl- (31.07 %), hexadecanoic acid, ethyl ester (2.66 %), phytol (1.18 %), 9,12-octadecadienoic acid, methyl ester (*E,E*)- (0.89 %), 7,11-hexadecadienal (1.18 %), octadecanoic acid, ethyl ester (0.59 %), isoparvifuran (5.33 %), 6H-benzofuro[3,2-c][1]benzopyran, 6a,11a-dihydro-3,9-dimethoxy- (6a*Rcis*)- [synonym:

homopterocarpin] (10.66 %), petrocarpin (15.68 %) and 1H-cycloprop[e]azulene, 1a,2,3,5,6,7,7a,7b-octahydro-1,1,4,7-tetramethyl-, [1aR-(1aà,7à,7aà,7bà)]-[synonym: varidiflorene] were found in *C. ternatea* aerial part extract (Sarumathy et al. 2011).

C. ternatea had been reported to have cyclotides, plant-derived proteins with a unique cyclic cystine knot topology and to play a role in host defence as well as to have a diverse range of pharmaceutically important activities, including uterotonic activity and antimicrobial and anti-HIV activity and had attracted recent interest as templates in drug design (Poth et al. 2011a). The scientists confirmed the expression and correct processing of the cyclotide encoded by the Cter M precursor gene transcript following extraction from *C. ternatea* leaf. Seven additional cyclotide sequences were also identified from *C. ternatea* leaf and flower, five of which were unique. Cter M displayed insecticidal activity against the cotton budworm *Helicoverpa armigera* and bound to phospholipid membranes, suggesting its activity to be modulated by membrane disruption. Further they found 12 novel cyclotides in the seeds (Poth et al. 2011b).

Phytochemicals in Roots

Taraxerone and taraxerol were isolated from *C. ternatea* roots (Banerjee and Chakravarti 1963, 1964). The concentration of taraxerol was found to be 12.4 mg/g w/w in the hydroalcoholic extract of *C. ternatea* root (Kumar et al. 2008).

Agrobacterium rhizogenes-transformed root cultures of butterfly pea were found to produce up to fourfold more yield of taraxerol, the anti-cancer triterpenoid compound compared to that in natural roots (Swain et al. 2012).

Phytochemical studies reported that the root-bark contained starch, taraxerol, tannin and resins; the seeds contained a fixed oil, bitter acid resin, tannic acid and 6 % ash and an alkaloid. The flowers were found to contain anthocyanins such as ternatins and preternatins and flavonol glyco-

sides; kaempferol 3-*O*-(2''-*O*- α -rhamnosyl-6''-*O*-malonyl)- β -glucoside; quercetin 3-*O*-(2''-*O*- α -rhamnosyl-6''-*O*-malonyl)- β -glucoside; myricetin 3-*O*-(2'',6''-di-*O*- α -rhamnosyl)- β -glucoside; kaempferol and quercetin 3-(2(G)-rhamnosylrutinoside); kaempferol, quercetin and myricetin 3-neohesperidosides, 3-rutinosides and 3-glucosides; and myricetin 3-*O*-(2''-*O*- α -rhamnosyl-6''-*O*-malonyl)- β -glucoside.

Antioxidant Activity

Terahara and Nishiyama (2000) considered ternatins as good radical-scavenging type antioxidants. Crude pigment extract from blue flowers of butterfly pea, containing ternatins (delphinidin 3-malonylGs connected with a series of 3', 5'-GC... side chains (G: D-glucose, C: p-coumaric acid)), was reported to have potential as new multifunctional natural pigment for a food colourant, cosmetic and disease-preventing food material. Some reasons stipulated were the relatively high antioxidative activity of ternatin B and D groups, the stable colour of ternatins in aqueous solution and the safe traditional usage of the crude pigments as food colourant in Southeast Asia. The leaves and blue and white flowers of *Clitoria ternatea* exhibited significant antioxidant activity with the blue flower-bearing plant showing higher scavenging activity (Sivaprabha et al. 2008). Aqueous *C. ternatea* flower extracts were shown to have stronger antioxidant activity (as measured by DPPH scavenging activity) than ethanol extracts (IC₅₀ values were 1 mg/ml and 4 mg/ml, respectively) (Kamkaen and Wilkinson 2009). Aqueous extracts incorporated into an eye gel formulation were also shown to retain this activity; however, it was significantly less than a commercial anti-wrinkle cream included for comparison. The total phenolic content was 1.9 mg/g extract as gallic acid equivalents.

Methanol root extracts of blue- and white-flowered varieties of *C. ternatea* showed more potent antioxidant activity in DPPH radical-

scavenging assay than the pet ether or chloroform extracts (Patil and Patil 2011). The methanol root extracts also showed significant reductive ability as well as hydroxyl radical scavenging activity. The antioxidant activity of *C. ternatea* methanol leaf extract was 67.85 % at a concentration of 1 mg/ml and was also concentration dependent, with an IC_{50} value of 420.00 μ g/ml (Nithianantham et al. 2011). The amount of total phenolics and flavonoids were estimated to be 358.99 mg/g gallic acid equivalent and 123.75 mg/g catechin equivalent, respectively.

Antidiabetic Activity

Oral administration of aqueous extract of *C. ternatea* leaves (400 mg/kg body weight) and flowers (400 mg/kg body weight) for 84 days significantly reduced serum glucose, glycosylated haemoglobin, total cholesterol, triglycerides, urea, creatinine and the activity of gluconeogenic enzyme glucose-6-phosphatase, but increased serum insulin, HDL-cholesterol, protein, liver and skeletal muscle glycogen content and the activity of glycolytic enzyme glucokinase (Daisy et al. 2009). For all the above biochemical parameters investigated, *C. ternatea* leaves treated rat showed a little better activity than *C. ternatea* flowers treated diabetic rats. In another study, the ethanol seed extract of *C. ternatea* at 400 mg/kg body weight dose significantly decreased blood glucose, cholesterol, alkaline phosphatase, aspartate amino transferase and alanine amino transferase in diabetic rats when compared to streptozotocin-induced diabetic control (Kalyan et al. 2011). Ethanol extract showed the presence of various phytoconstituents, namely, sterols, alkaloids, glycosides, saponins, tannins, carbohydrates, proteins, phenolic compounds and flavonoids. Dried plant extracts of roselle, chrysanthemum, mulberry, bael and butterfly pea were found to have in-vitro inhibitory effects on intestinal α -glucosidase and pancreatic α -amylase (Adisakwattana et al. 2012). They reported that the use of plant-based foods and their combinations with inhibitory effects on intestinal α -glucosidase (maltase and sucrase) and pancreatic

α -amylase could help prevent the onset of diabetes by controlling postprandial hyperglycaemia resulting in aggressive delay of carbohydrate digestion to absorbable monosaccharide. Phytochemical analysis revealed that the total phenolic content of the dried plant extracts were in the range of 460.0–230.3 mg gallic acid equivalent/g dried extract. The dried extracts contained flavonoid in the range of 50.3–114.8 mg quercetin equivalent/g dried extract. It was noted that the IC_{50} values of chrysanthemum, mulberry and butterfly pea extracts were 4.24, 0.59 and 3.15 mg/ml, respectively. Further, the IC_{50} values of chrysanthemum, mulberry and butterfly pea extracts against intestinal sucrase were 3.85, 0.94 and 4.41 mg/ml, respectively. In addition, the IC_{50} values of roselle and butterfly pea extracts against pancreatic α -amylase occurred at concentration of 3.52 and 4.05 mg/ml, respectively. Combining roselle, chrysanthemum and butterfly pea extracts with mulberry extract showed additive interaction on intestinal maltase inhibition.

Antimicrobial/Insecticidal Activity

The aqueous, methanol and chloroform extracts of *C. ternatea* flowers exhibited activity against uropathogenic *Escherichia coli*, enteropathogenic *Escherichia coli*, enterotoxigenic *Escherichia coli*, *Salmonella typhimurium*, *Klebsiella pneumoniae* and *Pseudomonas aeruginosa* (Uma et al. 2009). However, the petroleum ether and hexane extracts did not exhibit any activity. The methanol leaf extract of *C. ternatea* was found to possess a more potent inhibitory activity effect against *Bacillus cereus*, *Staphylococcus aureus*, *Klebsiella pneumonia*, *Proteus vulgaris* and *Salmonella typhi* when compared to the petroleum ether and ethyl acetate extracts (Anand et al. 2011).

Finotin a small basic protein was isolated from the seeds was found to be antimicrobial and insecticidal (Kelemu et al. 2004). It exhibited broad and potent inhibitory effect on the growth of various important fungal pathogens of plants, namely, *Rhizoctonia solani*, *Fusarium solani*, *Colletotrichum lindemuthianum*, *Lasiodiplodia*

theobromae, *Pyricularia grisea*, *Bipolaris oryzae* and *Colletotrichum gloeosporioides*. It also inhibited the common bean bacterial blight pathogen *Xanthomonas axonopodis* pv. *phaseoli*. Finotin also had powerful inhibitory properties against the bean bruchids *Zabrotes subfasciatus* and *Acanthoscelides obtectus*. *Clitoria ternatea* leaf extract showed a favourable antifungal activity against *Aspergillus niger* with a minimum inhibition concentration 0.8 mg/ml and minimum fungicidal concentration 1.6 mg/ml (Kamilla et al. 2009). The leaf extract exhibited considerable antifungal activity on hyphal growth of *A. niger*. There was loss of cytoplasm in fungal hyphae and the hyphal wall, and its diameter became markedly thinner and distorted and resulted in cell wall disruption. In addition, conidiophore alterations were also observed.

Central Nervous System Activity

The alcoholic extracts of aerial and root parts of *C. ternatea* at 300 and 500 mg/kg doses administered orally to rats were capable of attenuating electroshock-induced amnesia (Taranalli and Cheeramkuzhy 2000). Extracts at 300 mg/kg dose produced significant memory retention, and the root parts were found to be more effective. They found that *C. ternatea* extracts increased rat brain acetylcholine content and acetyl cholinesterase activity in a similar fashion to the standard cerebroprotective drug pyritinol. Jain et al. (2003) reported *Clitoria ternatea* to possess nootropic, anxiolytic, antidepressant, anticonvulsant and antistress activities. A methanol extract of *Clitoria ternatea* was found to impact on the central nervous system. The extract decreased time required to occupy the central platform (transfer latency, TL) in the elevated plus maze (EPM) and increased discrimination index in the object recognition test, indicating nootropic activity. The extract was more active in the object recognition test than in the EPM. The extract increased occupancy in the open arm of EPM by 160 % and in the lit box of the light/dark exploration test by 157 %, indicating its anxiolytic activity. It decreased the duration of immobility in tail sus-

pension test (suggesting its antidepressant activity), reduced stress-induced ulcers and reduced the convulsing action of PTZ and MES. The extract exhibited tendency to reduce the intensity of behaviour mediated via serotonin and acetylcholine. Recent studies by Malik et al. (2011) also showed that *C. ternatea*, commonly used as a component ingredient in the well-known Ayurveda herbal drug Shankhpushpi, exhibited nootropic, anxiolytic and CNS-depressant activity.

Neonatal rat pups (7 days old) intubated with either 50 mg/kg body weight or 100 mg/kg body weight of aqueous root extract of *Clitoria ternatea* for 30 days resulted in memory enhancement (Rai et al. 2001). There was improvement in retention and spatial learning performance at both time points of behavioural tests in neonatal rat pups, indicating the memory enhancing property of the extract which implicated a permanent change in the brain of extract treated rats. Another study showed that the plant extract enhanced memory. Treatment with 100 mg/kg of *Clitoria ternatea* aqueous root extract, for 30 days in neonatal and young adult age groups of rat, significantly increased acetylcholine (ACh) content in their hippocampi as compared to age matched controls (Rai et al. 2002). Increase in ACh content in their hippocampus may be the neurochemical basis for their improved learning and memory. Further Rai et al. (2005) found that the significant improvement in dendritic arborization of amygdaloid neurons correlated with the increased passive avoidance learning and memory in the extract treated rats. The results suggested that *Clitoria ternatea* aqueous root extract enhanced memory by increasing the functional growth of neurons of the amygdala.

Antiinflammatory, Analgesic and Antipyretic Activities

Clitoria ternatea also has antiinflammatory, analgesic and antipyretic attributes (Devi et al. 2003). Its methanol root extract when given by oral route to rats was found to inhibit both the rat paw oedema caused by carrageenan and vascular permeability induced by acetic acid in rats.

Moreover, the extract exhibited a significant inhibition in yeast-induced pyrexia in rats. In the acetic acid-induced writhing response, the extract markedly reduced the number of writhing at doses of 200 and 400 mg/kg (p.o.) in mice. The methanol root extract at doses of 200, 300 and 400 mg/kg body wt. p.o. produced significant reduction in normal body temperature and yeast-provoked elevated temperature in a dose-dependent manner. The effect extended up to 5 hours after the drug administration. The antipyretic effect of the extract was comparable to that of paracetamol (150 mg/kg body wt., p.o.), a standard antipyretic agent.

Antiplatelet Aggregating Activity

Anthocyanins ternatins (A1, A2, B1, B2, D1 and D2) isolated from *Clitoria ternatea* (double blue) were found to have blood platelet aggregation-inhibiting (Honda et al. 1991) and vascular smooth-muscle-relaxing activities.

Antihyperlipidaemic Activity

Oral administration of the hydroalcoholic extract of the roots and seeds of *C. ternatea* resulted in a significant reduction of serum total cholesterol, triglycerides, very low-density lipoprotein cholesterol and low-density lipoprotein cholesterol levels (Solanki and Jain 2010a). The atherogenic index and the HDL/LDL ratio were also normalized after treatment in diet-induced hyperlipidaemic rats. The effects were compared with atorvastatin (50 mg/kg, p.o.) and gemfibrozil (50 mg/kg, p.o.), reference standards. The authors attributed the cholesterol-lowering effect of *C. ternatea* to increased biliary excretion and decreased absorption of dietary cholesterol.

Hepatoprotective Activity

The results of the paracetamol-induced liver toxicity studies showed that mice treated with the methanol extract of *C. ternatea* leaf (200 mg/kg)

showed a significant decrease in aspartate aminotransferase (AST), alanine aminotransferase (ALT) and bilirubin levels, which were all elevated in the paracetamol group (Nithianantham et al. 2011). *C. ternatea* leaf extract therapy also had protective effects against histopathological alterations. In another study, *C. ternatea* seed extract significantly decreased SGOT, SGPT, ALP and total bilirubin in both acetaminophen and CCl₄-intoxicated rats (Solanki and Jain 2011). The *C. ternatea* root extract showed similar results only in CCl₄-intoxicated rats. Hepatic collagen content as evident from decreased hydroxyproline levels and hepatic mast cell infiltration were significantly decreased in extracts pretreated animals. In addition, *C. ternatea* seed extracts significantly reduced hepatic lipid peroxidation as evident from the decreased MDA and increased antioxidant enzyme activities and GSH levels in the liver tissues. They suggested that the hepatoprotective activity of *C. ternatea* could be attributed to antioxidant properties and prevention of pre-inflammatory changes. They suggested that the hepatoprotective action was likely related to its potent antioxidative activity.

Nephroprotective Activity

Oral administration of the ethanol extract of *C. ternatea* plant elicited nephroprotective activity against acetaminophen-induced nephrotoxicity in male albino rats (Sarumathy et al. 2011). Biochemical studies showed that there was an increase in the levels of serum urea and creatinine along with an increase in the body weight and reduction in the levels of uric acid in acetaminophen-induced animals. These values were reverted significantly by treatment with *Clitoria ternatea* extracts at two different doses of 250 and 500 mg/kg body weight. The antioxidant studies revealed that the levels of renal SOD, CAT, GSH and GPx in the APAP-treated animals are increased significantly along with a reduced MDA content in ethanol extract of *Clitoria ternatea*-treated groups. Further, histopathological changes also revealed the protective nature of the *Clitoria ternatea* extract against

acetaminophen-induced necrotic damage of renal tissues.

Immunomodulatory Activity

C. ternatea seed and root extracts showed significant immunosuppressive effects as evident from significant decrease in primary and secondary antibody titres in SRBCs-sensitized rats, paw thickness in delayed type hypersensitivity (DTH) response and neutrophil adhesion and in-vitro phagocytosis (Solanki and Jain 2010b). They attributed the immunomodulatory effects of *C. ternatea* on humoral, cell-mediated and nonspecific immune response to decreased immune cell sensitization, immune cell presentation and phagocytosis. They also asserted that the antiinflammatory and antioxidant properties of plant might be playing major role in immunomodulatory activity.

Wound Healing Activity

C. ternatea seed and root extracts significantly improved wound healing in excision, incision and dead-space models in rats when administered orally by gavage as well as applied topically as ointment (Solanki and Jain 2012). These effects were comparable to that of cotrimoxazole ointment. The findings suggested that *C. ternatea* affected all three phases— inflammatory, proliferative and remodeling phases of wound healing. The plant extracts were found to contain phenolic compounds and seed extract was containing flavonol glycosides.

Antinutrient Activity

Three trypsin inhibitors with molecular weights of 20, 12 and 7 kDa and with one-chain molecule were isolated from the seeds (Macedo and Xavier-Filho 1992). The 20-kDa inhibitor had arginine in the reactive site, the 12-kDa had lysine in the reactive site, and both belonged to the Kunitz and Bowman–Birk families, respectively. The small molecular weight inhibitor

(7 kDa) also had an arginine in the reactive site and was probably of the Bowman–Birk type. The seeds were found to have oligosaccharides which could be completely removed by 2 minutes roasting; germination resulted only in 30–40 % of total oligosaccharide (Revilleza et al. 1990).

Anthelmintic Activity

Clitoria ternatea was found to have an anthelmintic activity (Khadatkar et al. 2008). A crude alcoholic extract and its ethyl acetate and methanol fractions significantly demonstrated paralysis and also caused death of worms (*Pheretima posthuma*) especially at higher concentration of 50 mg/ml, as compared to standard reference piperazine citrate.

Antihistaminic Activity

The ethanol extract of *Clitoria ternatea* root was found to have antihistaminic activity using clonidine- and haloperidol-induced catalepsy in mice (Taur and Patil 2011b).

Antiasthmatic Activity

The ethanol extract of *Clitoria ternatea* root significantly decreased milk-induced leukocytosis and eosinophilia, protected egg albumin-induced degranulations of mast cells in mice and inhibited area of blue dye leakage in passive cutaneous anaphylaxis in rats at (100–150 mg/kg, i.p.) (Taur and Patil 2011a). Phytochemical studies observed the presence of steroids, saponin, flavonoids and glycosides. The results suggested that the antiasthmatic activity of ECTR may be due to the presence of flavonoids or saponins.

Mosquito Larvicidal Activity

Among the methanol extracts of *C. ternatea* leaves, roots, flowers and seeds, the seed extract was effective against the larvae of all the three

major mosquito vectors *Aedes aegypti*, *Culex quinquefasciatus* and *Anopheles stephensi* with LC₅₀ values 65.2, 154.5 and 54.4 ppm, respectively (Mathew et al. 2009). Among the three plant species (*Saraca indica/asoca*, *Nyctanthes arbor-tristis* and *Clitoria ternatea*) studied, *C. ternatea* showed the most promising mosquito larvicidal activity. The phytochemical analysis of the promising methanol extract of the seed extract was positive for carbohydrates, saponins, terpenoids, tannins and proteins.

Traditional Medicinal Uses

Clitoria ternatea, a traditional Ayurvedic medicine, has been used for centuries for many diseases and disorders. It has been employed as a memory enhancer, nootropic, antistress, anxiolytic, antidepressant, anticonvulsant, tranquilizing and sedative agent and used in the traditional Indian system of medicine as a brain tonic and is believed to promote memory and intelligence (Burkill 1966; Aiyar et al. 1973; Taranalli and Cheeramkuzhy 2000; Mukherjee et al. 2008; Wetwitayaklung et al. 2008; Anand et al. 2011; Malik et al. 2011; Kaisoon et al. 2001; Stuart 2012). The plant parts have been considered cooling, acrid, purgative, laxative, diuretic, antipyretic, antiinflammatory, analgesic and anthelmintic.

The root, leaves and flowers are used in the form of powder and decoction to treat oedema, mental disorder, goitre, vitiligo, snake poisoning, toothache, eye disease, fever, asthma, jaundice, earaches, pile, throat infections, skin diseases (boils and scabies), renal stones and filariasis, and also used as an aphrodisiac. In the Philippines, the leaves were employed as wet dressing for wounds; root decoction taken to treat inflammation of joints, and the seeds used in poultices for swollen joints. In Indonesia, the seeds are considered aperient, the roots are cathartic, the leaves are used as poultices, and juice of white flowers was used for inflamed eyes. In Thailand, the flowers are used as hair tonic, for hair growth, as stimulant and for hair colouring.

Other Uses

Butterfly pea is a multipurpose forage legume. It provides bioactive compounds for medicinal use and it is also an ornamental plant on fence rows, cover crop and green manure crop. Butterfly pea, a highly palatable forage legume, is generally preferred over other legumes by livestock such as sheep, goat and cattle. It has thin stem and large leaves, nil bloat and nontoxic which make it ideal for forage and haymaking. Its vigorous growth, tolerance to frost and dry periods and heavy grazing pressures make this suitable for wasteland development. It is used as a revegetation species on coal mines in central Queensland, Australia. When grown as green manure or ley pasture, it enhances soil fertility to improve yields of subsequent crops like maize, sorghum wheat. It is used as a cover crop in rubber, cocoa and coconut plantations.

The flowers are still widely used for making dye in Southeast Asia because they are rich in blue anthocyanin, a plant pigment. The dye is added to cosmetics, fabrics and shampoo (which helps keep dyed hair dark) and used as a food colourant. The blue dye is also used as a natural pH indicator in the pharmaceutical industry.

Comments

Clitoria ternatea is readily propagated from seed and by cuttings.

Yapese: Paar, Raar

Origin/Distribution

It is native to tropical Asia—from Taiwan and southern China through the Philippines, Indonesia, Malaysia, Thailand, Myanmar, India, islands in the Indian Ocean and all the way to tropical East Africa. Introduced and naturalized also in American and African tropical countries.

Agroecology

An adaptable species that grows in the humid tropics, subtropics and semiarid areas, occurring in zones with mean annual temperatures of 20–32 °C and mean annual rainfall of 800–

1,500 mm with 5–6 months of rainy periods. It occurs wild in deciduous forest from the coastal dunes and forests to an elevation of 1,500 m. It thrives best in full sun on a deep, well-drained, sandy loam, but they tolerate a wide range of soil conditions from sands to clays of pH 4.5–8.0. The tree is drought tolerant, fairly fire tolerant, and can tolerate brief periods of waterlogging.

Edible Plant Parts and Uses

Young and old leaves are eaten steamed or stewed as lalab with rice or mixed with other vegetables (Ochse and Bakhuizen van den Brink 1980). In Papua New Guinea, the leaves are eaten cooked (French 1986). The boiled flowers and young leaves are edible, cooked like string beans but in more water (Deane 2002–2012). Seeds are consumed after roasting or boiling but are poisonous when eaten raw (Burkill 1966). In Vietnam, the leaves of *E. variegata* are used to wrap ‘nem’ (a kind of fermented pork).

Botany

An erect much branched, medium-sized, deciduous tree up to 25 m high and a spread of 8–12 m. Stem smooth, greyish with large scattered conical prickles on the stem and branch. Leaves are alternate, trifoliate, 20–30 cm long, the terminal largest; leaflet-stalk glandular (Plates 1 and 2). Leaflets are triangular to broadly rhomboid-ovate, with acuminate tips and obtuse bases, shining green. Inflorescence in dense axillary and terminal racemes appearing before the leaves (Plates 1 and 3); rachis tomentose; bracts small; flowers bright red; calyx tubular, minutely 5-toothed; corolla long, standard broad, ovate-elliptical, shortly clawed and 7–9 cm long, wings and keel subequal; stamens 10, connate basally, exserted; ovary multi-ovuled, style glabrous, incurved (Plates 3 and 4). Pods are black, cylindrical, long up to 38 cm, dehiscent and constricted between the glossy, reddish brown reniform seeds. Each pod has 5–10 seeds.

Nutritive/Medicinal Properties

Leaf Nutrients/Phytochemicals

Food nutrient value of fresh leaves per 100 g edible portion reported is moisture 78.1 g, energy 69 kcal, protein 5.0 g, fat 0.7 g, carbohydrate 10.6 g, fibre 3.0 g, ash 2.6 g, Ca 639.1 mg, Fe 4.1 mg and P 109 mg (National Institute of Nutrition-University of Central Florida Project 2001–2004).

Erythraline and erythratine were isolated (Folkers and Koniuszy 1940). Leaves were reported to have a total alkaloidal content of 0.11 % constituting alkaloids erysotrine, erysodine, erysovine, erythaline, erysopine, erysopitine, erysonine, erysodienone, orientaline, hypaphorine, hypaphorine methyl ester and also N,N-dimethyltryptophan (Ghosal et al. 1970, 1972). From the leaves were isolated two alkaloids (erysothrine and hypaphorine) (Nguyen et al. 1991); two tetrahydropyridine alkaloids (scoulerine and (+)-coreximine); a benzyltetrahydroisoquinoline alkaloid (L-reticuline); a dibenz[d, f]azone alkaloid (erybidine); O-methylerybidine and N-norreticuline (Ito et al. 1973); scoulerine and coreximine (Ito 1999); 10,11-dioxoerythratidine (Herlina et al. 2005); phytol (Herlina et al. 2006); isolate 11 characterized as a triterpene pentacyclic 3b-11a-28-trihydroxy-oleane-2-ene and isolate 17 as a mixture of β -sitosterol and stigmasterol (Herlina et al. 2008); pentacyclic triterpenoid

(3,22,23-trihydroxy-oleane-12-ene); pentacyclic triterpenoid (3b,11a-28trihydroxy-oleane-12-ene); and 10,11-dioxoerythratidine (Supratman et al.2010). Kalachaveedu et al. (2011) extracted β -sitosterol (433 mg, 1.445 w/w), oleanolic acid (65 mg, 0.217 % w/w) and β -sitosterol glycoside (108 mg, 0.36 % w/w).

The leaf was found to contain a lectin with molecular weight of 58 kDa, made up of two sub-unit molecular weights of 30 and 33 kDa (Konozy et al. 2002). The leaf lectin was found to be a glycoprotein with a neutral sugar content of 9.5 %. The leaf lectin was rich in acidic as well as hydrophobic amino acids and totally lacked cysteine and methionine. The N-terminal amino acids were Val-Glu-Thr-Ile-Ser-Phe-Ser-Phe-Ser-Glu-Phe-Glu-Ala-Gly-Asn-Asp-X-Leu-Thr-Gln-Glu-Gly-Ala-Ala-Leu-.

Flower Phytochemicals

The alkaloid, erythratine, elucidated as 11-hydroxyerysotrine, was isolated from the flowers in Egypt (El-Olemy et al. 1978). The flowers were found to contain 7-methoxy 8-(15-OH pentadecyl)-coumarin; phaseollin; 29-norcycloartenol; 3- β -acetoxy- β -norcholest-5-ene; docosanoic and capric acid; flavonoid abyssinone; prenylated isoflavonoids stigmoids A, B and C, besides isoquinoline alkaloids erythritol; and isoquinoline alkaloid isococcoline, isoflavones alpinumisoflavone, erythrinin A,B and C, osajin and erythrabasin I (Sharma and Chawla 1992; Chawla and Sharma 1993). Two isoquinoline alkaloids designated erythrosotidienone and erythromotidienone plus stigmasterol, cycloartenol and erysotramidine were isolated from the acetone flower extract (Sharma and Chawla 1998).

Seed Phytochemicals

Marañón and Santos (1932) found an alkaloid, a fatty oil, and a saponaceous glucoside from the seeds. The alkaloid isolated had the properties identical with those of hypaphorine. From seeds

erythraline and 'free' and 'liberated' erysovine were isolated (Singh and Chawla 1970). The fatty acid composition of the seed oil was also determined. A prenylated flavone glycoside 5,7,4'-trihydroxy-3'-methoxy-8-C-prenylflavone 7-*O*- β -D-glucopyranosyl-(1 \rightarrow 3)- α -L-arabinopyranoside (1) was isolated from the seeds (Yadava and Reddy 1999). Nitrogen contents of *E. variegata* seeds and deoiled seeds showed good protein content; albumin, globulin, prolamine and glutelin were separated out by fractionation (Samanta and Laskar 2008). Fractionation of protein was done to separate albumin, globulin, prolamine and glutelin. The total protein isolates (TPI) and the fractions isolated contained 17 amino acids, most of which were essential.

A D-galactose-binding glycoprotein lectin was purified from the seeds (Datta and Basu 1981). A mitogenic D-galactosephilic lectin was isolated from seeds (Gilboa-Garber and Mizrahi 1981). Kunitz-type trypsin inhibitors, ETIa and ETIb, and chymotrypsin inhibitor ECI were isolated from the seeds (Kouzuma et al. 1992). The proteins ETIa and ETIb comprised 172 and 176 amino acid residues with molecular weight 19,242 and 19,783, respectively, and shared 112 identical amino acid residues, about 65 % identity. A chymotrypsin inhibitor (ECI) isolated from seeds was found to have 179 amino acid residues with a pyroglutamic acid as the N-terminal residue and has a calculated molecular weight of 19,791 (Kimura et al. 1993). About 60 % of the residues of ECI were identical to those of ETIa and ETIb and the reactive sites, Arg63, in ETIa and ETIb were changed to Leu64 in ECI. A Bowman-Birk family proteinase inhibitor (EBI) isolated from the seeds was found to consist of 61 amino acid residues, the shortest among the Bowman-Birk family inhibitors sequenced to date, and with a molecular weight of 6,689 (Kimura et al. 1994). EBI could be classified as a group II inhibitor, showing the best homology (67 %) to the Bowman-Birk proteinase inhibitor from soybeans. *Erythrina variegata* chymotrypsin inhibitor (ECI) and chymotrypsin molecules were found to undergo aggregation in the complex-forming buffer simultaneously with a binary complex consisting of one ECI and one

chymotrypsin molecule in a soluble form (Kimura et al. 1997). ECI comprised two peptides; the N-terminal peptide, ECI-(1-107)-peptide, containing the primary reactive site retained a slight inhibitory activity, while the C-terminal peptide, ECI-(108-179)-peptide, exhibited no inhibitory activity. It was demonstrated that amino acid residues Gln62 (P3), Phe63 (P2), Leu64 (P1) and Phe67 (P3') in the primary binding loop of *Erythrina variegata* chymotrypsin inhibitor (ECI), a member of the Kunitz inhibitor family, were involved in its strong inhibitory activity towards chymotrypsin (Iwanaga et al. 1998). It was further shown that the intramolecular interaction between the primary binding loop and the scaffold of ECI played an important role in the strong inhibitory activity towards chymotrypsin (Iwanaga et al. 1999).

The purified seed isolectins (EVL I, EVL II and EVL III) isolated from *E. variegata*, were all specific for galactopyranosides and N-acetyl-galactosamine, and their affinities for simple sugars were EVL III greater than EVL II greater than EVL I (Yamasaki et al. 1992). EVL I and EVL III were found to be homodimers made up of an A-subunit of molecular mass 36,000 and a B-subunit of molecular mass 33,000, whereas EVL II a heterodimer composed of the A- and B-subunits. They found that there was no structural difference of the sugar chains linked to the two subunits of *E. variegata* galactose-specific isolectins (Yamaguchi et al. 1993). This together with the results of amino acid sequence comparisons indicated that the difference in molecular mass of these two subunits resulted almost wholly from the difference in the number of oligosaccharides linked to them.

Stem/Bark/Wood Phytochemicals

The petroleum ether bark extract was found to compose of wax alcohols and wax acids, alkyl ferulates, alkyl phenolates, stigmasterol, sitosterol, campesterol and citrostadienol/24-methylenelophenol (Singh et al. 1975). The ethanol bark extract yielded chloroform-soluble and water-soluble bases, identified as erysovine

and stachydrine, respectively. From the bark were isolated isoflavones (erythrins A, B, C, osajin; alpinumisoflavone; and oxyresveratrol and dihydroxyresveratrol) (Deshpande et al. 1977), alkaloids (erysotrine, erythratidine, *epi*-erythratidine and 11-hydroxy-*epi*-erythratidine) (Chawla et al. 1988), three flavonoid phospholipase A₂ (PLA₂) inhibitors (4'-hydroxy-3',5'-diprenylisoflavone (abyssinone V) and 3,9-dihydroxy-2,10-diprenyl-pterocarp-6a-ene (erycristagallin) and 4'-hydroxy-6,3',5'-triprenylisoflavone) (Hedge et al. 1997), erythrinin B (Kobayashi et al. 1997), alpinumisoflavone and two prenylated isoflavones (erythravarones A and B characterized as dihydroalpinumisoflavone and 4'-hydroxy-[6'',6''-dimethyldihdropyrano(2'',3'':5,6)]-[6'',6''-dimethyldihdropyrano(2'',3'':7,8)] isoflavone, respectively) (Huang and Yen 1996; 1997) and warangalone (Huang and Tseng 1998). Isoflavonoids, eryvarin A and eryvarin B, were isolated from wood (Tanaka et al. 2000). Two isoflavone derivatives named indicanines D and E together with 11 known compounds including six isoflavones (genistein, wighteone, alpinumisoflavone, dimethylalpinumisoflavone, 8-prenyl erythrinin C and erysenegalsein E), one cinnamate (erythrinassinate B), two pentacyclic triterpenes (oleanolic acid and erythrodiol) and two phytosterols (stigmasterol and its 3-*O*- β -D-glucopyranoside) were isolated from the stem bark (Nkengfack et al. 2001). Huang and Chiang (2004) isolated the following constituents from the methanol stem bark extract: triterpenoids, namely, lup-20(29)-en-3-one; β -amyrin; olean-12-en-3 β , 22 β -diol; olean-12-en-3 β , 28-diol; 22 β , 24-dihydroxyolean-12-en-3-one; oleanonic acid; oleanolic acid; and olean-12-en-3 β , 22 β , 24-triol along with warangalone and 6,8-diprenylkaempferol.

From the stem bark, three isoflavones (5,4'-dihydroxy-8-(3,3-dimethylallyl)-2''-methoxyisopropylfurano[4,5:6,7]isoflavone (1), 5,7,4'-trihydroxy-6-(3,3-dimethylallyloxiranylmethyl) isoflavone (2) and 5,4'-dihydroxy-8-(3,3-dimethylallyl)-2''-hydroxymethyl-2''-methylpyrano[5,6:6,7]isoflavone (3)) and a new isoflavanone, 5,4'-dihydroxy-2'-methoxy-8-(3,3-dimethylallyl)-2'',2''-dimethylpyrano[5,6:6,7]

isoflavanone (4), together with seven known compounds, euchrenone b10 (5), isoerysenegalsein E (6), wighteone (7), laburnetin (8), lupi-wighteone (9), erythrodiol (10) and oleanolic acid (11), were isolated (Li et al. 2006). Genistein derivatives mainly in the form of prenylgenistein from this extract, including 6-prenylgenistein, 8-prenylgenistein and 6, 8-diprenylgenistein, were isolated from the stem bark (Zhang et al. 2008). Warangalone 8(3,3-dimethyl-allyl)-4'-hydroxy-2'',2''-dimethylpyran[6,7,b]isoflavone was isolated from the stem bark (Herlina et al. 2009). The following secondary metabolites were isolated from the stem bark: alpinumisoflavone, 6-hydroxygenistein, 3 β ,28-dihydroxyolean-12-ene, epilupeol (Rahman et al. 2007) and three isoflavones (scandenone, 4',5,7-trihydroxy-8-prenylisoflavone and 4',5,7-trihydroxy-8-methylisoflavone) (Rahman et al. 2010). Liu et al. (2012) isolated erysopine and erysovine from the stem bark.

Root Phytochemicals

The following compounds were isolated from the roots: warangalone (scandenone), 5,7,4'-trihydroxy-6,8-diprenylisoflavone, erycristagallin, erythrabyssin-II, phaseollin, phaseollidin, isobavachin and a cinnamylphenol, eryvarietyrene (*E*-1-[2, 4-dihydroxy-5-(3-methylbut-2-enyl)]-2-phenylethylene) (Telikepalli et al. 1990); pterocarpan, dihydrofolin and erythrabyssin II, and the alkyl ester of ferulic acid, octacosyl ferulate (Ahmad et al. 2002); orientanol B (9-hydroxy-3-methoxy-2 γ , γ , dimethylallylpterocarpan), erycristagallin (3,9-dihydroxy-2,10-di(γ , γ -dimethylallyl)-6 α ,11 α -dehydropterocarpan), cristacarpin, sigmoidin K, 2-(γ , γ -dimethylallyl)-6 α -hydroxyphaseollidin, erytagallin A (3,6 α -dihydroxy-9-methoxy-2,10-di(γ , γ -dimethylallyl) pterocarpan) (Sato et al. 2002); two diphenylpropan-1,2-diols, eryvarinols A (1) and B (2) and their structures were elucidated as 1-(4-hydroxy-2-methoxyphenyl)-2-(4-hydroxy-3,5-dimethoxybenzoyloxy)-3-(4-hydroxyphenyl) propan-1-ol (1) and its 3''-prenyl derivative (2)

(Tanaka et al. 2002a); 3,9-dihydroxy-2,10-di(γ,γ -dimethylallyl)-6 α ,11 α -dehydropterocarpan (erycristagallin) and 9-hydroxy-3-methoxy-2- γ,γ -dimethylallylpterocarpan (orientanol B) (Tanaka et al. 2002b); two 3-phenoxychromones, eryvarins F and G, and their structures were elucidated as 3-(2,4-dihydroxyphenoxy)-7-hydroxy-6,8-di(3,3-dimethylallyl)chromen-4-one and 3-(2,4-dihydroxyphenoxy)-8-(3,3-dimethylallyl)-2,2-dimethylpyrano[5,6:6,7]chromen-4-one, respectively (Tanaka et al. 2003); three isoflavonoids, eryvarins M–O, two 2-arylbenzofurans, eryvarins P and Q, and a 3-aryl-2,3-dihydrobenzofuran, eryvarin R (Tanaka et al. 2004); two isoflavonoids, eryvarins S and T, and a new 2-arylbenzofuran, eryvarin U (Tanaka et al. 2005); a biisoflavonoid, biseryvarin A, was isolated from the roots (Tanaka et al. 2010); and two isoflavonoids, eryvarins V and W, and a chromen-4-one derivative, eryvarin X (Tanaka et al. 2011).

A 3-phenylcoumarin, indicanine A, was isolated from the root bark together with, robustic acid, daidzein and 8-prenyldaidzein (Nkengfack et al. 2000). The structure of the new compound was characterized as 4-hydroxy-5-methoxy-3-(4'-methoxyphenyl)-2''-(1-methylethenyl)dihydrofurano[4'',5'':6,7]coumarin. In addition to two known compounds, 5,4'-di-*O*-methylalpinumisoflavone and cajanin, a new 3-phenylcoumarin metabolite, named indicanine B, and a new isoflavone derivative, named indicanine C, were isolated from the root bark (Waffo et al. 2000). The structures of the new compounds were characterized as 4-hydroxy-3-(4'-hydroxyphenyl)-5-methoxy-2'',2''-dimethylpyrano [5'',6'':6,7] coumarin and 4'-hydroxy-5-methoxy-2'',2''-dimethylpyrano [5'',6'':6,7] isoflavone, respectively.

Antioxidant Activity

The crude methanol stem bark extract, n-hexane, carbon tetrachloride and chloroform soluble fractions showed moderate DPPH antioxidant activity (IC_{50} =484.4–82.35 μ g/ml), while the purified compounds, 4',5,7-trihydroxy-8-prenyl isoflavone alpinum isoflavone and 6-hydroxygenistein, exhibited high antioxidant activity, having IC_{50} of

6.42, 8.30 and 8.78 μ g/ml, respectively (Rahman et al. 2010). At the same time the standard compound, tert-butyl-1-hydroxytoluene (BUT), demonstrated an IC_{50} of 5.88 μ g/ml.

Studies showed that the aqueous and methanol leaf extracts exhibited significant DPPH radical scavenging activity with an IC_{50} value of 342.59 and 283.24 μ g/ml, respectively (Sakat and Juvekar 2010). The aqueous and methanol extracts significantly scavenged nitric oxide radicals (IC_{50} =250.12; 328.29 μ g/ml, respectively). Lipid peroxidation induced by thiobarbituric acid reactive substances (TBARS) was inhibited by the aqueous extract with low IC_{50} value (97.29 μ g/ml) as compared to methanol extract (IC_{50} =283.74 μ g/ml). Both the extracts exhibited similar quantities of total phenolics. Total flavonoids were found to be in higher quantities than total flavonols in aqueous extract as compared to methanol extract.

Antimicrobial Activity

Among the isoflavonoids isolated from *E. variegata*, 3,9-dihydroxy-2,10-di(γ,γ -dimethylallyl)-6 α ,11 α -dehydropterocarpan (erycristagallin) showed the highest antibacterial activity against mutants Streptococci, other oral Streptococci, *Actinomyces* and *Lactobacillus* species with a minimum inhibitory concentration (MIC) range of 1.56–6.25 μ g/ml, followed by 3,6a-dihydroxy-9-methoxy-2,10-di(γ,γ -dimethylallyl)pterocarpan (erycristagallin A) and 9-hydroxy-3-methoxy-2- γ,γ -dimethylallylpterocarpan (orientanol B) (MIC range: 3.13–12.5 μ g/ml) (Sato et al. 2002).

Fourteen out of 16 isoflavonoids isolated from the roots showed antibacterial activity in the concentration range (1.56–100 μ g/ml); the MIC values varied significantly among them (Tanaka et al. 2002b). Of the active compounds, 3,9-dihydroxy-2,10-di(γ,γ -dimethylallyl)-6 α ,11 α -dehydropterocarpan (erycristagallin) and 9-hydroxy-3-methoxy-2- γ,γ -dimethylallylpterocarpan (orientanol B) exhibited the highest activity against methicillin-resistant *Staphylococcus aureus* with MIC values of 3.13–6.25 μ g/ml. The phytochemical 2',4'-dihydroxy-8- γ,γ -dimethylallyl-2'',2''-dimethylpyrano[5'',6'':6,7]

isoflavanone (bidwillon B), isolated from *Erythrina variegata*, inhibited the growth of 12 methicillin-resistant *Staphylococcus aureus* (MRSA) strains at minimum inhibitory concentrations (MICs) of 3.13–6.25 mg/l, while MICs of mupirocin, an antibiotic, were 0.20–3.13 mg/l (Sato et al. 2004). The minimum bactericidal concentration (MBC) for bidwillon B and mupirocin against MRSA was 6.25–25 mg/l (MBC₉₀: 12.5 mg/l) and 3.13–25 mg/l (MBC₉₀: 25 mg/l), respectively. When bidwillon B and mupirocin were combined, synergistic effects were observed for 11 strains of MRSA (fractional inhibitory concentration indices, 0.5–0.75). The MBCs of mupirocin in the presence of bidwillon B (3.13 mg/l) were reduced to 0.05–1.56 mg/l. The results suggested that bidwillon B and mupirocin to be potent phytotherapeutics, and/or their combination may be useful in the elimination of nasal and skin carriage of MRSA.

Eryvarin Q, a 2-arylbenzofuran, isolated from the roots, showed potent antibacterial activity against methicillin-resistant *Staphylococcus aureus* (Tanaka et al. 2004). The isoflavonoid eryvarin U, isolated from the roots, exhibited potent antibacterial activity against methicillin-resistant *Staphylococcus aureus* (MRSA) strains (Tanaka et al. 2005).

The crude methanol bark extract showed comparatively strong growth inhibition of *Bacillus subtilis*, *Escherichia coli* and *Aspergillus niger*, while n-hexane soluble fraction of the methanol extract showed poor activity against most of the test microorganisms (Rahman et al. 2007). The carbon tetrachloride fraction of the methanol extract showed moderate growth inhibition of *Bacillus cereus*, *B. subtilis*, *E. coli*, *Pseudomonas aeruginosa*, *Shigella dysenteriae* and *Vibrio mimicus*. The chloroform soluble fraction showed strong activity against *B. cereus*, *B. subtilis*, *E. coli*, *P. aeruginosa* and *A. niger*. The aqueous soluble fraction showed significant activity against Gram-positive bacteria, namely, *B. cereus*, *B. subtilis*, *Sarcina lutea* and the Gram-negative bacteria, *P. aeruginosa*. This fraction also showed strong activity against *A. niger* and *Saccharomyces cerevisiae* and moderate activity against *Candida albicans*.

The isoflavonoid eryvarin W, isolated from the roots, exhibited potent antibacterial activity against methicillin-resistant *Staphylococcus aureus* (MRSA) strains (Tanaka et al. 2011). A biisoflavonoid, biseryvarin A, isolated from the roots showed low activity against methicillin-resistant *Staphylococcus aureus* (MRSA) (Tanaka et al. 2010).

Antitumour Activity

The ethyl acetate and n-butanol fraction of the ethanol stem bark extract but not the aqueous fraction promoted proliferation of the rat osteogenic sarcoma (UMR106), osteoblast-like (OB-like) cells (Li et al. 2006). Eleven compounds isolated from the ethyl acetate fraction including 4 new isoflavones and 7 known compounds, euchrenone b₁₀, isoerysenegalsein E, wighteone, laburnetin, lupiwighteone, erythrodiol and oleanolic acid, also stimulated UMR106 cell proliferation at concentrations of 5×10^{-8} to 5×10^{-6} mol/L but did not promote proliferation at 5×10^{-5} mol/L.

Among the proteinase inhibitors of *E. variegata*, EBI, which belongs to the Bowman-Birk family of inhibitors, was cytotoxic in relatively differentiated cells such as Molt4 and Jurkat derived from acute T lymphoblastic leukaemia (T-ALL) cells specifically, but ETIa and ECI, which are classified into Kunitz family inhibitors, did not (Ohba et al. 1998). The succinylation of lysine residue(s) of EBI led to about 50 % loss of the trypsin inhibitory activity as compared with the authentic EBI. When Molt-4 cells were incubated with this derivative, no significant cytotoxicity was observed, suggesting that the proteinase inhibitory activity might be involved in the cytotoxicity in human tumour cell lines. Erythrina alkaloid derivative, 10,11-dioxoerythratidine from the leaves, showed anticancer activity against breast cancer cell line T47D in vitro used with IC₅₀ 1.0 µg/ml (Herlina et al. 2005). The methanol leaf extract of *E. variegata* and its ethyl acetate fraction and two compounds from the fraction isolate 11 and 17 exhibited anticancer activity against breast cancer T47D cell line in vitro

(Herlina et al. 2008). The potency against breast cancer cells ranked in the order of isolate 17 > isolate 11 > ethyl acetate fraction > methanol extract. Isolate 11 was characterized as a triterpene pentacyclic 3b-11a-28-trihydroxy-oleane-2-ene and isolate 17 as a mixture of β -sitosterol and stigmasterol. Rahman et al. (2007) evaluated the lethality of the *n*-hexane, carbon tetrachloride, chloroform and aqueous soluble fractions of the methanol bark extract to brine shrimp on *Artemia salina*. The LC₅₀ were found to be 36.68, 4.67, 7.733 and 14.289 μ g/ml, respectively. The cytotoxicity exhibited by the carbon tetrachloride and chloroform soluble fractions was significant and comparable to the positive control (vincristine sulphate). The results suggested that these fractions may be useful as antiproliferative and antitumorous bioactive agents.

Erythrina variegata extract exhibited antitumour effect in-vivo using the Lewis lung cancer mice model (Zhang et al. 2009). It also exhibited in-vitro antitumour effect against liver cancer cells. The methanol stem bark extract of *Erythrina variegata* showed significant anticancer activity against breast cancer T47D cell lines in vitro using the sulforhodamine B (SRB) assay (Herlina et al. 2011). Its bioactive component erythragallin A showed potent anticancer activity against breast cancer T47D cell lines in vitro with IC₅₀ 3.3 μ g/ml. Xanthoxyletin isolated from *E. variegata* exhibited antiproliferative effects in-vitro against human gastric adenocarcinoma SGC-7901 cells (Rasul et al. 2011). Its inhibitory effects on cells were associated with the DNA damage, apoptosis through mitochondrial dysfunction and cell-cycle arrest at S phase in a dose-dependent manner. Xanthoxyletin also increased the production of reactive oxygen species in SGC-7901 cells.

Studies showed that treatment of Dalton's ascitic lymphoma-induced Swiss Albino mice with methanol root bark extract of *Erythrina variegata* significantly increased the life span and decreased cancer cell number and tumour weight (Baskar et al. 2010). The haematological parameters were also normalized by the extract in tumour-induced mice.

Antiinflammatory Activity

Total alkaloids extracted from the leaves were found to have antiinflammatory activity (Nguyen et al. 1992). Three isoflavones, abyssinone V (1), 4'-hydroxy-6,3',5'-triprenylisoflavonone (2) and erycrystagallin (3), isolated from the bark, exhibited phospholipase A2 (PLA2) inhibition with IC₅₀ values of 6, 10 and 3 μ M for 1–3, respectively (Hedge et al. 1997). The methanol leaf extract was found to have antiinflammatory activity as observed by reduction of the paw oedema (Verma et al. 2005). It contained indole alkaloids. Studies revealed that ethanol leaf extract of *E. variegata* produced above 90 % protection of the HRBC membrane from lysis due to hyposaline at dose level of 1,600 μ g/ml when compared to 100 % lysis induced in control (Balamurugan et al. 2010). The standard drug, diclofenac, produced 95.26 % protection at a concentration of 50 mg/100 ml. The prevention of hypotonicity-induced HRBC membrane lysis was taken as a measure of antiinflammatory activity.

Blood Clotting Activity

Studies indicated that *Erythrina variegata* Kunitz proteinase inhibitors possessed different potency towards serine proteinases in the blood coagulation and fibrinolytic systems, in spite of their high similarity in amino acid sequence (Nakagaki et al. 1996). ETIa and ETIb, two Kunitz family trypsin inhibitors, prolonged the activated partial thromboplastin time (APTT) and also the prothrombin time (PT) of human plasma, but the Kunitz family chymotrypsin inhibitor, ECI, and Bowman-Birk family inhibitor, EBI, from *E. variegata* hardly prolonged these times. Trypsin inhibitors ETIa and ETIb inhibited the amidolytic activity of factor Xa and ETIb but not ETIa-inhibited plasma kallikrein. Neither ETIa nor ETIb exhibited any inhibitory activity towards beta-factor XIIa and thrombin. Furthermore, trypsin inhibitors ETIa and ETIb inhibited plasmin, a serine proteinase in the fibrinolytic system, whereas ECI and EBI did not. Of the two *Erythrina variegata* trypsin inhibitors designated

ETIa and ETIb, ETIa was found to have the ability to inhibit tissue-type plasminogen activator (tPA), while ETIb did not (Kouzuma et al. 1997a). They found that Arg61 and Leu62 residues in ETIa were important in inhibiting tPA and also suggest that beside these two residues, the other amino acid(s) or other structural element may be involved in interaction of ETIa with tPA. They also found that site-specific mutation of Arg63 to Leu (aR63L) or Asp (aR63D) in ETIa resulted in abolition of the inhibitory activities towards both trypsin and tPA (Kouzuma et al. 1997b). The result suggested that Arg61 and Leu62 in ETIa, in addition to Arg63, may play an important role in the interaction with tPA.

Immunomodulatory Activity

A D-galactose-binding glycoprotein lectin agglutinating human erythrocytes was purified from the seeds (Datta and Basu 1981). The lectin possessed leucoagglutinating property. A mitogenic D-galactosephilic lectin isolated from seeds was found to be similar to the soybean lectin in being a glycoprotein of molecular weight around 110,000–120,000 and having D-galactosephilic activity (Gilboa-Garber and Mizrahi 1981). The lectin resembled soybean and *Pseudomonas aeruginosa* lectins, by binding to D-GALACTOSAMINE, N-acetyl-D-galactosamine, alpha-galactoside and beta-galactoside as well as to D-galactose. Like these lectins it absorbed onto either untreated or enzyme (papain or neuraminidase)-treated human red blood cells but exhibited a considerable mitogenic activity towards human lymphocytes (predominantly T cells) only after their treatment with neuraminidase. This lectin was different in regard to the intensity of their agglutinating activity towards erythrocytes obtained from different animals and human donors of diverse ABO blood groups. Li et al. (1990) found that the Gal beta 1-4GlcNAc beta 1-3(Gal beta 1-4GlcNAc beta 1-6)Gal sugar sequence, an I-antigen determinant, was essential for the high affinity binding of the oligosaccharides to the *Erythrina variegata* agglutinin (EVA). The binding affinity of *Erythrina corallodendron* (synonym of *E. variegata*)

seed lectin was found to be in the order N-acetyllactosamine>N-acetyl-D-galactosamine>α-galactoside and β-galactoside>D-galactose (Sudakevitz et al. 1991). Its ABO(H) blood group specificity revealed the following order of activity: O(H)I>A2I>O(H)i adult>A2BI>BI>O(H)i cord>AII>AII adult>BI cord>A1BI>Ai cord>ABi cord>OhI. The *Erythrina indica* (synonym of *E. variegata*) lectin showed a lower differentiation between the agglutination of O(H) and Oh erythrocytes. Both *Erythrina* seed lectins exhibited H/HI blood group preference.

Erythrina leaf lectin (EiLL) agglutinated all human RBC types, with a slight preference for the O blood group (Konozy et al. 2002). The carbohydrate specificity of lectin was directed towards D-galactose and its derivatives with pronounced preference for lactose. EiLL had pH optima at pH 7.0; above and below this pH lectin lost sugar-binding capability rapidly.

Anti-osteoporotic Activity

Studies by Zhang et al. (2007b) demonstrated that *Erythrina variegata* stem bark extract could suppress the high rate of bone turnover induced by oestrogen deficiency, inhibit bone loss and improve the biomechanical properties of bone in the ovariectomized rats. Daily oral administration of the plant extract at 300 and 600 mg/kg for 14 weeks to rats prevented the ovariectomy-induced increase in the serum osteocalcin, alkaline phosphatase and urinary deoxypyridinoline (DPD) levels. Histomorphometric analysis of the proximal end of the tibia showed that the extract prevented the oestrogen deficiency-induced decrease in trabecular thickness and trabecular area, as well as restoring the increase in trabecular separation in a dose-dependent manner. Also, the extract improved the energy absorption and stiffness of the mid-shaft of the rat femur. In a follow-up study, they isolated genistein derivatives mainly in the form of prenylgenistein from this extract, including 6-prenylgenistein, 8-prenylgenistein and 6, 8-diprenylgenistein (Zhang et al. 2008). They found genistein did not promote cell growth but genistein derivatives

exerted stimulatory effects on osteogenesis in UMR 106 cells. Further animal studies indicated that the protective effects of *E. variegata* stem bark extract on bone properties in ovariectomized rats were likely to be mediated by its inhibitory actions on the process of bone resorption via the suppression of osteoclast differentiation and maturation (Zhang et al. 2010). The extract inhibited the upregulation of cathepsin K mRNA and the downregulation of osteoprotegerin mRNA in the tibia of ovariectomized rats.

Calcium Homeostasis Activity

Oral administration of *Erythrina variegata* extracts could improve the serum Ca level and inhibit urinary Ca excretion in ovariectomized rats and maintain Ca homeostasis, and this might be attributed to the upregulation of the extract on vitamin D receptor mRNA expression in the duodenum and CaBP-9k mRNA expression in the kidney (Zhang et al. 2007a).

β -Glucosidase Inhibitory Activity

In the β -glucosidase inhibitory bioassay, the crude methanol extract, n-hexane, carbon tetrachloride and chloroform soluble fractions of *E. variegata* stem bark revealed 34.75, 95.04, 91.49 and 55.32 %, inhibition, respectively (Rahman et al. 2010).

Hypotensive Activity

The aqueous seed extract elicited a sharp fall in blood pressure and at higher dose completely stopped the heart in guinea pigs (Chatterjee et al. 1981). It also produced a contraction of isolated guinea pig ileum. The fall in blood pressure and contraction of ileum were completely blocked by an antihistaminic agent—diphenhydramine. The extract did not show any CNS activity, since it neither affected the barbiturate-induced sleeping time nor protected the pentylenetetrazol-induced convulsions, although it depressed the respiration

at higher doses but stimulate the same in smaller doses in guinea pigs.

Antimalarial Activity

Erythrina alkaloid derivative, 10,11-dioxoerythratidine from the leaves, showed antimalarial activity against both strains of *Plasmodium falciparum* in-vitro used with IC₅₀ of 25.5 μ g/ml against strain 3D7 and 3.3 μ g/ml against K1 (Herlina et al. 2005). The methanol leaf extract of *E. variegata* exhibited significant antimalarial activity in-vitro towards *Plasmodium falciparum* (Herlina et al. 2007). Its *n*-butanol fraction gave the most potent activity, exhibiting equipotency against both strains of the parasite with IC₅₀ of 5.1 μ g/ml against K1 and 13.2 μ g/ml against 3D7. The methanol bark extract of *E. variegata* showed significant antimalarial activity towards *Plasmodium falciparum* in vitro using the lactate dehydrogenase (LDH) assay (Herlina et al. 2009). Its ethyl acetate fraction showed the highest activity, exhibiting equipotency against both strains of parasite with IC₅₀ of 23.8 μ g/ml against 3D7 and 9.3 μ g/ml against K1. The active component of the fraction isolated was identified as warangalone, 8(3,3-dimethylallyl)-4'-hydroxy-2''',2'''-imethylpyran[6,7,b]isoflavan which showed significant antimalarial activity against both strains with IC₅₀ of 4.8 μ g/ml against 3D7 and 3.7 μ g/ml against K1. The methanol stem bark extract of *Erythrina variegata* showed significant antimalarial activity against *Plasmodium falciparum* in-vitro using the lactate dehydrogenase (LDH) assay (Herlina et al. 2011). Its bioactive component erythagallin A showed potent antimalarial activity against both strains of parasite in-vitro used with IC₅₀ of 0.02 μ g/mL against 3D7 and 6.0 μ g/mL against K1, respectively. The pentacyclic triterpenoid, 3,22,23-trihydroxy-oleane-12-ene (1); pentacyclic triterpenoid, 3b,11a-28trihydroxy-oleane-12-ene (2); and 10,11-dioxoerythratidine (3) isolated from the ethyl acetate fraction of the methanol extract of dried leaves showed antimalarial activity (Supratman et al. 2010). Compound 3 showed antimalarial higher than compounds 1

and 2 against *P. falciparum* K1 strains resistant to chloroquine due to the presence of epoxy group in pyran ring.

Antihyperlipidaemic Activity

The elevated levels of total cholesterol, triglycerides, low-density lipoprotein and very low-density lipoprotein due to high-fat diet (HFD) was significantly reduced by concurrent treatment with methanol seed extract of *E. variegata* (200 and 400 mg/kg) (Balamurugan and Shantha 2010). A significant reduction in high-density lipoprotein was found in HFD-fed groups; however, a nonsignificant increment was produced by the administration of the extract. The extract reduced the elevated body weight and mesenteric fat pad weight and the enhanced HMG-CoA reductase activity of HFD hyperlipidaemic rats. The extract also significantly reduced antioxidant enzymes such as superoxide dismutase and catalase and lipid peroxidation in HFD rats. Administration of *E. variegata* leaf extract to guinea pigs fed on a high-fat diet reduced TC (33 %), triglyceride (TGL; 39 %) and LDL (36 %), while high-density lipoprotein (HDL) levels remained unaltered demonstrating its marginal hypolipidaemic influence (Kalachaveedu et al. 2011). Atherosclerotic changes in coronary histopathology caused by the high-fat diet were altered beneficially by the leaf extract.

Hypoglycaemic Activity

The methanol leaf extract of *E. variegata* exhibited promising hypoglycaemic action in streptozotocin (STZ)-induced diabetic rats substantiating its ethnomedicinal use (Kumar et al. 2011). The extract administered orally at doses of 300, 600 and 900 mg/kg significantly and dose-dependently reduced and normalized blood glucose levels as compared to that of STZ control rats, the 900 mg/kg dose being the most potent showing complete normalization of blood glucose levels. Serum biochemical parameters including lipid profile were significantly restored towards

normal levels in the extract-treated rats as compared to STZ diabetic rats.

Antidiarrhoeal Activity

The ethanol leaf extract significantly modified normal defecation frequency as well as inhibited castor oil-induced diarrhoea in Wistar rats (Sonia et al. 2011). The extract also displayed a significant reduction in gastrointestinal motility in charcoal meal test. The findings suggested that the ethanol extract of leaves of *Erythrina indica* elicited potent antidiarrhoeal effects substantiating its traditional claim as an antidiarrhoeal agent.

Diuretic Activity

The ethanol, chloroform and ethyl acetate leaf extracts exhibited significant diuretic activity as evidenced by increased total urine volume and the urine concentration of Na⁺, K⁺ and Cl (Jesupillai et al. 2008). The results supported the use of the plant as a diuretic agent in traditional medicine.

Antifertility Activity

Phytol from *E. variegata* leaves exhibited antifertility effects on the spermatozoa of white rats (*Rattus norvegicus*) in-vitro at a concentration of 0.25×10^3 µg/µl (Herlina et al.).

Spasmolytic Activity

Total alkaloidal fraction from bark caused smooth muscle relaxation of isolated rabbit ileum and inhibited spontaneous rhythmic contraction of isolated rat uterus in concentration of 0.5–2.0 mg/ml (Ghosal et al. 1972). *E. variegata* behaved like a spasmolytic agent due to its relaxing activity, thus may have an important role in conditions like diarrhoea or spasm or colic pain. Erythrinin B from *E. variegata* bark significantly

inhibited the Na⁺/H⁺ exchange system of arterial smooth muscle cells, with minimum inhibitory concentrations of 1.25 µg (Kobayashi et al. 1997).

CNS (Central Nervous System) Activity

The total alkaloid fraction from the bark showed several characteristic pharmacological effects: neuromuscular blocking, smooth muscle relaxant, CNS depressant, hydrocholeretic and anticonvulsant effects, which were consistent with the reported uses of the plant extracts in the indigenous system of medicine (Ghosal et al. 1972). The ethanol, chloroform and ethyl acetate leaf extracts of leaves showed significant ($P < 0.05$) anticonvulsant activity against maximal electroshock (MES) and pentylenetetrazol (PTZ)-induced convulsions in mice (Rajamanickam and Sathyanarayanan 2008). Ethanol extract gave more prominent activity when compared to other extracts.

The aqueous leaf extract showed potent sedative activity but no analgesic effects, as claimed by Sri Lankan Ayurvedic physicians (Ratnasooriya and Dharmasiri 1999). The methanol leaf extract showed mild sedative hypnotic activity when evaluated using pentobarbital (Verma et al. 2005). However, in a later study, the methanol leaf extract was found to have analgesic activity. In acetic acid-induced writhing model, the methanol leaf extract of the leaf of *E. variegata* at a dose of 500 mg/kg showed significant antinociceptive activity with 49.03 % inhibition of writhing response (Haque et al. 2006). In radiant heat tail-flick model, the extract also showed significant increase in the tail-flick latency at a dose of 500 mg/kg body weight with 36.02 % elongation of tail-flick time. As the crude extract appeared to be active in both animal models of nociception, it may possess peripherally and centrally acting compounds for its antinociceptive action.

Marañón and Santos (1932) isolated an alkaloid from the seeds which had properties identical with those of hypaphorine. Hypaphorine had been found to promote sleep in mice (Ozawa et al. 2008).

Toxicity Activity

The leaves and bark were found to contain the toxic alkaloid, erythrinine, a central nervous system depressant with effects similar to the alkaloid cytosine (Greshoff 1890; Nellis 1997). Symptoms reported included vomiting, malaise, lethargy and depression (Nellis 1997). Erythrinine was also isolated from the plant by Ito et al. (1970).

Traditional Medicinal Uses

A wide range of chemical compounds have been isolated, mainly alkaloids, flavonoids, triterpenoids and lectin from *E. variegata*. In Asia and the Pacific Islands, different parts of the plant have been used in traditional medicine for a variety of ailments and as nervine sedative, collyrium in ophthalmia, antiasthmatic, antiepileptic, antiseptic, astringent, febrifuge, anti-bilious, diuretic, laxative, expectorant, anthelmintic, vermifuge and an astringent (Crevost and Petelot 1928; Burkill 1966; WHO 1998; Rahman et al. 2007, 2010; Stuart 2012; Kumar et al. 2010).

The bark is used as a laxative, diuretic, expectorant astringent, febrifuge, anti-bilious and anthelmintic and is useful in ophthalmia and skin diseases. The bark is also employed to facilitate the maturation of boils. Dried bark decoction or infusion in alcohol is used for lumbar and leg pain. The stem bark is used against rheumatism in the form of a decoction, extract or tincture and an infusion used for stomachache. The bark when crushed and pounded is used for curing toothache by inserting into cavities or hollow tooth. The bark is chewed for dysentery. A mixture of bark scrapings and lime is applied to reduce swellings. The inner bark is scraped and mixed with little water; the juice is squeezed and drunk to cure cough with sore throat. The wood is rasped in water and given for haematuria. The bark and leaves are used in 'paribhadra', an Indian preparation as a vermifuge, for treating filariasis, and to relieve joint pain. A decoction of the bark and leaves, sweetened, is considered a good expectorant. The leaves and bark were found to contain the toxic alkaloid, erythrinine, a central nervous

system depressant with effects similar to the alkaloid cytosine (Greshoff 1890; Nellis 1997).

The leaves are employed in fever, inflammation and joint pains and as laxative, diuretic and expectorant. Heated crushed wet leaves are rubbed over the head and body of a person with fever. The juice of the leaves is used in earache, toothache, constipation and cough, and consuming the leaves is held to stimulate lactation, appetite and menstruation. The extract from crushed leaf mixed with water is drunk to relieve cough. Crushed fresh leaves are used externally as a poultice in haemorrhoids and metropstosis. Powdered leaves are topically applied for wounds and ulcers, and a warm poultice is applied externally to relieve rheumatic joints. Leaves are reported to be sedative and are used for the relief of insomnia and anxiety and for treating asthma. Leaves are crushed with seawater and drunk daily to relieve stomachache. Honeyed leaf juice is used as vermifuge for tapeworm and roundworm infestations. Pulverized leaves in the form of snuff are used for infantile convulsion and ascariasis. Leaves mixed with castor oil are used as therapy for dysentery.

The roots and leaves are considered to be febrifuge. The root decoction is used as a gargle for loose and aching teeth and an infusion used for bronchitis. Seeds used internally and externally for cancer and externally for abscesses. Pounded seeds are used as poultice for snake bites and for abscesses and cancerous growths.

Other Uses

Erythrina variegata is a multipurpose tree and an important agroforestry species. The species is simultaneously used as leaf forage and medicinal plant (in Vietnam especially grown for official purposes). It has also proven valuable for fodder production and as sturdy windbreaks. It is a useful plant for soil enrichment as it fixes nitrogen, nodulating readily and prolifically in both acid and alkaline soils and is also a good source of organic matter for green manure. In Asia and other tropical countries, it is a common ornamental tree for landscape, avenue planting and fencing/hedging

purposes. It is also used as live support tree for black pepper, betel leaf, jasmine, grapes and yams and as a shade tree for coffee and cocoa. The soft and white timber has been used for making packing cases, floats, picture frames and toys, and recently pulp for the paper industry.

Erythrina variegata has insecticidal activity. Two alkaloids isolated from the stem bark, identified as erysopine and erysovine, exhibited antifeedant activity against maize weevil *Sitophilus zeamais* adults with EC₅₀ values of 108.5 and 89.7 ppm, respectively (Liu et al. 2012). The D-galactose binding lectin from *E. indica* seeds significantly reduced egg hatching, pupation and emergence of the melon fruit fly, *Bactrocera cucurbitae* (Singh et al. 2009). Treatment of the larvae with the lectin significantly suppressed the activity of hydrolase enzymes (acid and alkaline phosphatases), one oxidoreductase (catalase) and one group transfer enzyme (glutathione S-transferases), but the esterases increased significantly.

Studies showed that *E. variegata* leaf powder could remove metal pollutant from solution. One study showed *E. variegata* leaf powder could bioadsorb zinc from aqueous solution (Venkateswarlu et al. 2008). There was a significant increase in percentage removal of Zn as pH increased from 2 to 3 and attained maximum at pH 7. In a subsequent study they found that *E. variegata* leaf powder could remove cadmium from solution; a significant increase in percentage removal of cadmium was observed as pH increased from 2 to 4 (Kumar et al. 2009).

Comments

E. variegata is readily propagated from seeds and woody stem cuttings.

Gliricidia sepium

Scientific Name

Gliricidia sepium (Jacq.) Kunth ex Walp.

Synonyms

Galedupa pungam Blanco, *Gliricidia lambii* Fernald, *Gliricidia maculata* (Kunth) Walp., *Gliricidia maculata* var. *multijuga* Micheli, *Gliricidia sepium* (Jacq.) Kunth ex Griseb., *Lonchocarpus rosea* (Mill.) DC., *Lonchocarpus sepium* (Jacq.) DC., *Millettia luzonensis* A. Gray, *Millettia splendidissima* sensu Naves, non Blume, *Robinia maculata* Kunth, *Robinia rosea* Mill., *Robinia sepium* Jacq., *Robinia variegata* Schltdl.

Family

Fabaceae

Common/English Names

Gliricidia, Glory Cedar, Mexican Lilac, Mother Of Cocoa, Nicaraguan Cacao Shade, Quick Stick, St. Vincent Plum, Tree Of Iron

Vernacular Names

Brazil: Mãe-Do-Cacau, Planta-Mãe-Do-Cacau

Columbia: Matarratón

Creole: Piyon

Cuba: Mata Ratón, Piñón Amoroso, Piñón Florido

Eastonian: Tara-Gliritsiidia

French: Immortelle, Lilas Étranger, Madre De Cacao

Guatemala: Madre De Cacao, Madre Cacao

Honduras: Madreado

India: Saranga (Bengali), Gobbarda Mara (Kannada), Kona, Seema Konna (Malayalam), Seemai Agathi (Tamil), Madri (Telugu)

Indonesia: Gamal, Liriksidia

Sri Lanka: Kona, Maikona Gaha, Seemakonna

Thai: Kha Farang, Khae-Farang

Venezuela: Ratón

Vietnamese: Anh Đào Gisa, Hồng Mai, Sát Thu

Origin/Distribution

G. sepium is indigenous to the seasonal dry forest areas of Mexico and Central America, namely, Belize, Costa Rica, El Salvador, Guatemala, Honduras and Nicaragua. It is now widely distributed in tropical Americas, the Caribbean, Africa, Asia and the Pacific Islands.

Agroecology

A warm tropical tree species grows in areas with warm, seasonally dry climates with moderate mean annual rainfall (900–1,500 mm). It thrives best in areas with mean annual temperatures of 20–27 °C and tolerates high temperatures of 36–42 °C and low temperatures down to 14 °C (Elevitch and Francis 2006). Night temperature lower than 5 °C is detrimental to the tree. The tree is extremely frost sensitive. The tree grows in climates with summer, winter, bimodal rainfall or uniformly distributed rainfall patterns, with mean annual precipitation of 600–3,500 mm. It is largely deciduous during the dry season but is evergreen in areas with uniformly distributed rainfall as in Kalimantan, Indonesia.

In its native range in Central America, it is often found on highly eroded soils of volcanic origin with pH 4.5–6.2 from near sea level to 1,200 m altitude. It is adaptable to a wide range of soil types—on sands, heavy clays and slightly alkaline, calcareous limestone soils—but does best in well-drained soils. *Gliricidia* abhors wet or waterlogged soils. *Gliricidia* tolerates fires well and trees quickly re-sprout with onset of the rains.

Edible Plant Parts and Uses

Gliricidia leaves and flowers are said to be eaten boiled or fried. In Mexico, the flowers are utilized as food (Delizo and Del Fierro 1974). Flowers are cooked in egg batter and fried or cooked as potherbs (Williams 1981; Facciola 1990). The flowers attract honeybees and are a good source of nectar.

Botany

A small unarmed, branched tree reaching heights of 10–12 m with smooth, weakly fissured, greyish-brown bark and a trunk diameter of 30 cm at breast height (dbh). Leaves alternate, imparipinnate, 15–30 cm long with 7–21 leaflets (Plate 1). Leaflets, pubescent when young, glabrous when mature, green, ovate-lanceolate to elliptic, 2–6 cm by 1–3 cm, acute to acuminate apex, rounded to acute bases and entire margin. Inflorescences borne on distal end of leafless branches, 5–15 cm long, with 20–40 flowers per raceme (Plates 2–3). Flowers bright pink to lilac, tinged with white, petals 5, standard petal usually with a diffuse pale yellow spot at the base, broad about 20 mm long, keel petals oblong, curved, 15–20 mm long, 4–7 mm wide, calyx—five toothed, glabrous, green, often tinged red, stamens 10 with whitish

Plate 1 Flowers and leaves (CT Ho)

Plate 2 Axillary inflorescences (CT Ho)

Plate 3 Flower buds (CT Ho)

Plate 4 Open flowers (CT Ho)

filaments, ovary reddish with a white style (Plates 1, 2, and 4). Pod oblongate, 10–18 cm long, 2 cm wide, green sometimes with reddish tinge when unripe, light yellow-brown when mature, valves twisting in dehiscence; seeds 4–10, yellow-brown to brown, nearly round.

Nutritive/Medicinal Properties

Phytochemical from Fruits/Seeds

Three saponins hederagenin-3-*O*-(4-*O*-acetyl- β -D-xylopyranosyl)-(1 \rightarrow 3)- α -L-hamnopyranosyl-(1 \rightarrow 2)- α -L-arabinopyranoside, hederagenin-3-*O*-(3,4-di-*O*-acetyl- β -D-xylopyranosyl)-(1 \rightarrow 3)- α -L-rhamnopyranosyl-(1 \rightarrow 2)- α -L-arabinopyranoside and hederagenin-3-*O*-(3,4-di-*O*-acetyl- α -L-arabinopyranosyl)-(1 \rightarrow 3)- α -L-rhamnopyranosyl-(1 \rightarrow 2)- α -L-arabinopyranoside were isolated from the fruits (Kojima et al. 1998).

Proximate nutrient composition of the seed was reported as crude fat 24.70 %, crude protein 18.7 %, crude fibre 3.01 %, ash 4.06 %, moisture 4.10 %, carbohydrate 45.41 %, Na 342.57 ppm, K506.55 ppm, Ca 293.10 ppm, Mg 83.65 ppm, Fe 128.11 ppm, Cu 1.10 ppm, Zn 21.78 ppm and Mn 32.30 ppm (Adewuyi et al. 2009). The lipid classes of the seed oil comprised polar lipids 7.50 %, sterols 2.70 %, diacylglycerols 5.30 %, monoacylglycerols 4.60 %, triacylglycerols 75.60 %, hydrocarbons 1.90 % and free fatty acids 2.40 %. The mineral content of the seed oil comprised Na 281.10 ppm, K 432.60 ppm, Ca 271.10 ppm, Mg 64.70 ppm, Fe 102 ppm, Cu 0.60 ppm, Zn 16.80 ppm and Mn 22.98 ppm. The physicochemical characteristics of the seed oil was reported as colour orange, acid value 1.40 mg KOH/g, free fatty acid 0.80 %, saponification value 94.4 mg KOH/g, iodine value 87.60 mg I/g, unsaponifiable matter 1.00 %, peroxide value 0.40 mg O₂/g oil, refractive index (25 °C) 1.4, specific gravity (25 °C) 0.876 and sate at room temperature liquid. The composition of the unsaponifiables of the seed oil comprised n-alkanes 21.20 %, triterpene alcohols 31 %, sterols 29.4 % and unknowns 18.40 % (Adewuyi et al. 2009).

Sotelo et al. (1986) have reported a thermostable non-protein amino acid toxin canavanine (2-amino-4-guanidooxy-butyric acid) in gliricidia seeds which killed mice within 1 week of feeding and may be associated with the toxicity of gliricidia in non-ruminants.

Phytochemical from Flowers

In the flower essential oil, the major compounds were coumarin (43.1 %), hydroquinone (21.6 %), myrtenol (12.73 %) and maltol (4.62 %) (Kaniampady et al. 2007). Other compounds included *p*-mentha-1,8-dien-9-ol 1.83 %, octanoic acid 1.53 %, 3-nonanol 1.5 %, 2-butyl-2-hexanol 1.46 %, γ -nonalactone 1.31 %, 2-octanoic acid 1.26 %, 2-butyl-3-hexenol 1.03 %, eucarvone 0.88 %, myrtenal 0.78 %, *p*-mentha-1,4-diene-2-ol 0.73 %, geraniol 0.72 %, *p*-mentha-1,4-diene-7-ol 0.71 %, dodecanoic acid 0.64 %, nonanol

0.62 %, tetradecanoic acid 0.46 %, allyl tiglate 0.44 %, 4-hydroxy-3-methylacetophenone 0.37 %, 3tetradecanoic acid 0.36 %, benzyl alcohol 0.35 %, decanoic acid 0.31 % and dihydrocarveol acetate 0.30 %.

Jose and Reddy (2010) reported the following chemical composition of the flower essential oil: coumarin 43.07 %, hydroquinone 21.64 %, myrtenol 12.73 %, maltol 4.42 %, *p*-mentha-1,8-dien-1-ol 1.83 %, γ -nonalactone 1.31 %, 2-butyl-2-hexanol 1.03 %, eucarvone 0.88 %, myrtenal 0.78 %, *p*-mentha-1,4-dien-2-ol 0.73 %, geraniol 0.72 %, *p*-mentha-1,4-dien-7-ol 0.71 %, dodecanoic acid 0.64 %, nonanol 0.62 %, nonanoic acid 0.55 %, tetradecanoic acid 0.46 %, benzyl alcohol 0.35 % and decanoic acid 0.31 %.

Phytochemicals from Leaves

G. sepium leaf meal was found to have the following amino acid composition: threonine 1.2 %, valine 1.60 %, cysteine 0.39 %, methionine 0.42 %, isoleucine 1.20 %, leucine 2.41 %, tyrosine 1.12 %, phenylalanine 1.54 %, lysine 1.12 %, histidine 0.51 % and arginine 1.59 % (Chadhokar 1982).

The leaves were found to contain coumarin, *O*-coumaric acid and melilotic acid (Griffiths 1962), cyanogenic glycoside, nitrate (Manidool 1985), pinitol (Calle et al. 1987), condensed tannins (Ahn et al. 1989) and lignans (pinoresinol and lariciresinol) (Ragasa et al. 2000). *G. sepium* leaves were found to contain condensed tannins (CT) which were all bound to proteins (Jackson et al. 1996). Two new triterpene saponins (1 and 2) possessing 3 β ,21 β ,24-trihydroxy-22-oxoolean-12-ene as an aglycon and oligosaccharide moiety linked to C-3 of the aglycon were isolated from leaves and roots (Rastrelli et al. 1999b). They contained two pyranoses (glucuronic acid and xylose) and the glucose residue of both 1 and 2 was also linked to C-21.

The major compounds of the leaf essential oil were propylene glycol (25.1 %), coumarin (18.2 %), (*Z*)-3-hexenol (17.7 %), β -farnesene (14.2 %) and (*E*)-2-hexenol (6.5 %) (Kaniampady et al. 2007). Other compounds included thymol

(3.6 %), benzyl alcohol 3.5 %, caryophyllene (2.3 %), α -farnesene (2.0 %), 2-pentene-1-ol (<1 %), isovanillin (<1 %), isobutyl alcohol (<1 %), phenylethyl alcohol (<1 %), phenol (<1 %), crotonic aldehyde (<1 %) and 5,6-dihydro-4*H*-cyclopenta-(6)-furan (<1 %). Jose and Reddy (2010) reported the following chemical composition of the leaf essential oil: propylene glycol 25.1 %, coumarin 18.2 %, (*Z*)-2-hexenol 17.7 %, β -farnesene 14.2 %, (*E*)-2-hexenol 6.5 %, thymol 3.6 %, benzyl alcohol 3.5 %, caryophyllene 2.3 %, α -farnesene 2.0 %, 2-pentene-1-ol <1 %, isovanillin <1 % < isobutyl alcohol <1 %, phenylethyl alcohol <1 %, phenol <1 %, crotonic aldehyde <1 % and 5,6-dihydro-4*H*-cyclopenta-(6)-furan <1 %.

Phytochemicals from Bark, Heartwood, Root

Jurd and Manners (1977) isolated two new isoflavones, 2',3',7-trihydroxy-4'-methoxyisoflav-3-ene (sepiol) and 3',7-dihydroxy-2',4'-dimethoxyisoflav-3-ene (2'-*O*-methysepilol); a new phenolic isoflavan, robinetin; and 7,3',4'-trihydroxyflavanone from gliricidia heartwood. Three additional flavonoid constituents (an isoflavone, a dihydroflavonol and a β -hydroxydihydrochalcone) were isolated from the wood (Manners and Jurd 1979). An isoflavan, 7,4'-dihydroxy-3'-methoxyisoflavan, along with three other isoflavonoids (isovestitol, formononetin and afrormosin), a pterocarp, medicarpin, 4-hydroxy-3-methoxy-cinnamaldehyde (Herath et al. 1998), stigmasterol glucoside and 3',4'-dihydroxy-*trans*-cinnamic acid octacosylester, along with three other known constituents (Herath and de Silva 2000), were isolated from the heartwood. From the methanol extract of *Gliricidia sepium* bark, Rastrelli et al. (1999a) isolated in addition to vestitol and 2'-*O*-methylvestitol, three new 12 α -hydroxyrotenoids: gliricidol, 2-methoxy gliricidol and gliricidin. Hederagin was also isolated from the roots (Rastrelli et al. 1999b).

Nineteen compounds were identified and quantified from the bark volatile oil of *Gliricidia sepium* (Reddy and Jose 2010a). The major com-

ponents were methyl-3(*E*)-pentenyl ether (11.55 %), 3-methyl-2-butanol (10.65 %), 3-methoxy hexane (10.14 %), 1-(1-ethoxyethoxy)-2-hexene (9.72 %), 2-decanol (8.97 %), coumarin (8.07 %) and hexadecanoic acid (5.16 %). Other components included humulene epoxide (3.64 %), caryophyllene oxide (3.05 %), 2,4-dimethyl-3-hexanol (2.79 %), 2-ethyl hexanol (2.61 %), dodecanoic acid (2.37 %), methyl-3(*E*)-hexenyl ether (2.19 %), 4-ethoxy ethyl benzoate (2.1 %), 1-hexanol (1.92 %), *T*-muurolool (1.77 %), tetradecanoic acid (1.23 %), octadecanal (1.11 %) and methyl-3-butenyl ether (1.02 %).

Antioxidant Activity

G. sepium ethanol extract exhibited low DPPH radical scavenging activity but showed the highest ferric reducing antioxidant property of 88 % (Akharaiyi et al. 2012). *G. sepium* extract had the highest concentration of phenol with a value of 1.7 mg/ml and flavonoid content with a value of 0.46 mg/ml.

Antimicrobial Activity

Of 153 Panamanian plants tested, the crude plant extracts of *G. sepium* were one of three that showed most promising inhibitory activity in-vitro against *Candida albicans* and *Cladosporium cucumerinum* (Rahalison et al. 1993).

The methanol bark extracts of *G. sepium* exhibited antimicrobial effects against *Staphylococcus epidermidis*, *Staphylococcus aureus*, *Pseudomonas aeruginosa*, *Bacillus pumilus* and *Vibrio cholerae* at doses of 200 µg (Pérez et al. 2001). *Gliricidia sepium* leaf alcohol extract was one of ten Guatemalan plants found to be most active in-vitro against five strains of *Neisseria gonorrhoeae* (Cáceres et al. 1995), and the bark and leaf extracts were found to be inhibitory to four pathogenic fungi, namely, *Aspergillus flavus*, *Epidermophyton floccosum*, *Microsporum gypseum* and *Trichophyton rubrum* (Cáceres et al. 1993). *G. sepium* bark oil exhibited pro-

nounced activity against all tested microorganisms *Bacillus cereus*, *Enterobacter faecalis*, *Salmonella paratyphi*, *Staphylococcus aureus*, *Escherichia coli*, *Streptococcus faecalis*, *Proteus vulgaris*, *Klebsiella pneumoniae*, *Pseudomonas aeruginosa* and *Serratia marcescens*, and its activity was quite comparable with the standard antibiotics screened under similar conditions (Reddy and Jose 2010a).

Lignans: pinoresinol and lariciresinol isolated from *gliricidia* leaves exhibited low antimicrobial activity against *Bacillus subtilis* and *Pseudomonas aeruginosa* and antifungal activity against *Trichophyton mentagrophytes* and *Aspergillus niger* (Ragasa et al. 2000). The ethanol leaf extract of *G. sepium* exhibited antibacterial activity against *Escherichia coli*, *Staphylococcus aureus*, *Pseudomonas* spp., *Salmonella typhi* and *Klebsiella* spp., with the best result against *E. coli* (Nazli et al. 2008).

The methanol, ethyl acetate and chloroform extracts of *Gliricidia* flowers exhibited significant activity against all the tested organisms, namely, *Bacillus cereus*, *Enterobacter faecalis*, *Salmonella paratyphi*, *Staphylococcus aureus*, *Escherichia coli*, *Streptococcus faecalis*, *Proteus vulgaris*, *Klebsiella pneumoniae*, *Pseudomonas aeruginosa* and *Serratia marcescens* (Reddy and Jose 2010b). Flower aqueous extract was found to be effective on *Escherichia coli*, *Proteus vulgaris*, *Bacillus cereus*, *Enterobacter faecalis*, *Pseudomonas aeruginosa*, *Staphylococcus aureus* and *Serratia marcescens* but elicited little effect on *Salmonella paratyphi*, *Klebsiella pneumoniae* and *Streptococcus faecalis*. The bark ethyl acetate extract exhibited marked activity against *Bacillus cereus*, *Enterobacter faecalis*, *Salmonella paratyphi*, *Escherichia coli*, *Proteus vulgaris*, *Pseudomonas aeruginosa* and *Serratia marcescens* but was inactive against *Staphylococcus aureus*, *Streptococcus faecalis* and *Klebsiella pneumoniae*. The bark methanol extract was found to be active against *Bacillus cereus*, *Enterobacter faecalis*, *Salmonella paratyphi*, *Streptococcus faecalis*, *Pseudomonas aeruginosa*, *Serratia marcescens*, *Staphylococcus aureus* and *Proteus vulgaris* but was inactive against *Escherichia coli* and *Klebsiella pneu-*

moniae. Both chloroform and aqueous extracts of *Gliricidia sepium* bark inhibited the growth of *Bacillus cereus*. Chloroform extract inhibited *Bacillus cereus*, *Escherichia coli* and *Pseudomonas aeruginosa*. Bark aqueous extract exhibited appreciable activity against *Serratia marcescens*, *Bacillus cereus*, *Salmonella paratyphi* and *Streptococcus faecalis* but was less active against *Staphylococcus aureus*, *Pseudomonas aeruginosa* and *Klebsiella pneumoniae*. Petroleum ether extracts of bark, leaf and flower had no antibacterial activity on the test microorganisms.

Leaf methanol extract showed appreciable inhibitory activity on all test bacteria except *Serratia marcescens*. The leaf aqueous extracts of *Gliricidia sepium* was found to be effective on *Escherichia coli* and *Serratia marcescens* but had little effect on *Salmonella paratyphi*, *Staphylococcus aureus*, *Klebsiella pneumoniae* and *Pseudomonas aeruginosa*. *Gliricidia sepium* essential leaf exhibited potent antibacterial activity against *Salmonella paratyphi*, *Streptococcus faecalis*, *Proteus vulgaris*, *Serratia marcescens* and *Enterobacter faecalis*, and the activity was quite comparable with the standard antibiotics screened under similar conditions (Jose and Reddy 2010). The activity of leaf oil was found to be higher than flower oil. Ethanol leaf extract of *G. sepium* demonstrated antimicrobial activity against bacteria and fungi in-vitro (Nazali et al. 2011). The MIC value of 1 mg/ml was found for Gram-positive bacteria (*Staphylococcus aureus*, *Streptococcus intermedius*, *Bacillus pumilus*, *B. subtilis* and *B. cereus*) and 0.5 mg/ml for Gram-negative bacteria (*Salmonella typhi*, *Escherichia coli*, *Klebsiella pneumoniae*, *Proteus mirabilis* and *Shigella flexneri*). The MIC value for fungi was higher 2 mg/ml for *Fusarium solani*, *Rhizomucor pusillus*, *Trichophyton rubrum*, *Macrophomina phaseolina* and *Rhizoctonia solani*; *Aspergillus effusus* was resistant to the extract.

The crude ethanol extract and fractions of *G. sepium* showed higher antibacterial activity than the methanol extract (Akharaiyi et al. 2012). Growth of the following bacteria was inhibited to varying degree: *Pseudomonas aeruginosa*, *Serratia marcescens*, *Escherichia coli*,

Enterococcus faecium, *Salmonella typhi*, *Bacillus cereus*, *Proteus mirabilis*, *Staphylococcus aureus* and *Klebsiella pneumoniae*.

Studies showed that aqueous extracts from 22 Guatemalan plants including *Gliricidia sepium* tested inhibited one or more of the dermatophytes (Cáceres et al. 1991). The most commonly inhibited dermatophytes were *Epidermophyton floccosum* (43.2 %), *Trichophyton rubrum* (36.0 %) and *Trichophyton mentagrophytes* (31.8 %); the less inhibited were *Microsporum canis* (22.7 %) and *Microsporum gypseum* (24.0 %). In a study of scabies treatment among selected residents of Titay, Zamboanga, kakawati (*G. sepium*) preparation was found to be as effective as sulphur lotion in the treatment of scabies (Bañez et al. 1999). A significant difference was observed between pretreatment and posttreatment scores after 1 week. However, there was a noted increase of scabies lesions 2 and 4 weeks after. In a randomized, double-blind clinical trial, a 50 % *Gliricidia sepium* (kakwate/madre de cacao) ointment was found comparable with 2 % miconazole ointment in terms of mycologic cure and safety profile, but it was not as effective as 2 % miconazole in improving overall clinical response and reducing major signs and symptoms of *Tinea corporis* and *Tinea cruris* (Guillano and Alabado 2002). Coumarin isolated from the water leaf extract inhibited growth of *Trichophyton mentagrophytes* in-vitro an average antimicrobial index (AI) of 1.45, while the standard clotrimazole showed inhibition of AI at 2.0 (Rabena 2007).

Neuropharmacological Activity

At dosage of 1.25 g dried plant/kg weight aqueous extracts of bark and leaves of *Byrsonima crassifolia* and *Gliricidia sepium* demonstrated the most neuropharmacological activity: decrease in motor activity, back tonus, reversible palpebral ptosis, catalepsy and strong hypothermia (Morales et al. 2001). These extracts elicited very significant reductions in spontaneous locomotor activity, exploratory behaviour and rectal temperature, and they increased the sodium pentobarbital-induced sleeping time.

Cytotoxicity Activity

Gliricidol, 2-methoxygliricidol and gliricidin isolated from *Gliricidia* bark, exhibited activity against the brine shrimp *Artemia salina* larvae (Rastrelli et al. 1999a).

Antimalarial Activity

Significant in-vivo antimalarial activity against *Plasmodium berghei* was observed with the ethyl acetate and aqueous extracts of *Gliricidia sepium* leaves (Castro et al. 1996). Compounds identified include flavonoids, coumarins, melilotic acid and iridoids.

Mosquitocidal Activity

The ethanol leaf extract of *G. sepium* demonstrated 78 % repellency against *Aedes aegypti* compared with 74 % with citronella oil (Nazli et al. 2008). Results of studies revealed that ethanol extract of *G. sepium* showed significant larvicidal, ovicidal and pupicidal activity against malarial vector, *Anopheles stephensi* (Krishnappa et al. 2012). The ethanol extract elicited maximum mortality of larvae at 250 ppm concentration with LC₅₀ value of 121.79 ppm and LC₉₀ value of 231.98 ppm. Highest concentration of both solvent extracts exhibited 100 % ovicidal activity as assessed by egg hatchability. Similarly, pupae exposed to different concentrations of ethanol extract were found dead with 58.10 % adult emergence when it was treated with 25 ppm concentration. Similarly, 18.36 ($n=30$; 61.20 %), 21.28 (70.93 %,) and 27.33 (91.10 %) pupal mortality was recorded from the experimental pupae treated with 50, 75 and 100 ppm concentration of extracts.

Anthelmintic Activity

Of three forage legume, *Calliandra calothyrsus*, *Gliricidia sepium* and *Leucaena diversifolia*, *G. sepium* was found to be more active (2.9 and

0.0 % for embryonation and egg hatching of *Haemonchus contortus*, respectively) than *C. calothyrsus*, 16.5 and 33.5 %, and for *L. diversifolia* 33.7 and 33.3 %, respectively (Wabo Poné et al. 2011). Studies by von Son-de Fernex et al. (2012) found that the lyophilized leaf extract of *G. sepium* (1,200 µg of extract/ml) inhibited motility of *Haemonchus contortus* infective larvae.

Trypanocidal Activity

The ethanol extract of *G. sepium* bark showed some trypanocidal activity in-vitro against the protozoa, *Trypanosoma cruzi* (Berger et al. 1998).

Toxicity Studies

Studies by Gale et al. (1954) found that extracts of mature and young leaves, fruit, seeds and roots of *G. sepium* appeared to be devoid of any toxicity to mature albino rats. No mortality of rats was found that could be attributable to *Gliricidia* extracts administered.

Sotelo et al. (1986) have reported a thermo-stable toxin canavanine in gliricidia seeds which killed mice within 1 week of feeding and may be associated with the toxicity of gliricidia in non-ruminants. Ahn (1990) also found depressed intakes, weight loss and foetal deaths in rats offered a diet containing 20 % dried gliricidia leaf. Gliricidia bark and seeds were reported to be used as a rat poison in some countries (Sotelo et al. 1986), suggesting the presence of a toxic principle.

Traditional Medicinal Uses

In Mexico, the plant is used as an antihistaminic, antipyretic, expectorant and diuretic; crushed fresh leaves are applied as a poultice (Elevitch and Francis 2006). In Saint Lucia, the leaves are brewed as tea, sweeten and drank for cough and asthma; the leaves are also useful for skin infections (Slane 1987). Peasant in San Jacinto in

northern Columbia uses the flower liquid to clean eyes (Bonzani 1999). In Panama, decoction of leaves is used for urticaria, rash and also in burns and erysipelas (Jose and Reddy 2010). In Guatemala and Costa Rica, bark decoction is used against bacterial and protozoal infections (Berger et al. 1998). However, their study showed that no fraction of *G. sepium* bark showed marked trypanocidal activity against *Trypanosoma cruzi*. *G. sepium* extracts have been used to treat infections produced by *Microsporium canis*, *Trichophyton mentagrophytes* and *Neisseria gonorrhoeae* (Gupta 1995).

In the Philippines, leaf juice or decoctions of the leaf, root and bark are employed for scabies and dermatitis and as antipruritic on the skin; fresh leaves are applied to skin as insect repellent, and crushed leaves applied for rheumatic pains, sprains and closed fractures (Stuart 2012). Sap of bark, leaves and roots has also been used for wound healing. In Guatemala, the bark and leaves are used to treat skin diseases, and in other countries, the plant is used for headache, bruises, burns, colds, cough, fever, fatigue, gangrene, gonorrhoea, skin itches and sores and as antidote, insecticide and insect repellent (Stuart 2012).

Other Uses

Gliricidia is often planted as a living fence; the foliage is harvested and used as green manure and cut-and-carry fodder for large and small ruminants, and the branched are lopped for fuel wood. The leaves of *G. sepium* have a high feeding value with crude protein comprising 26.1 % of the dry matter, a crude fibre content of about 9.14 % and in-vitro dry matter digestibility of 62.8 % (Adejumo and Ademosun 1985). When feeding three browse plants to goats, the tannin and saponin in the leaves of *Gliricidia sepium*, *Manihot esculenta* and *Spondias mombin* were found significantly to influence dry matter intake, nitrogen intake and nitrogen balance but not body weight gain in West African dwarf goats (Onwuka 1992). Gliricidia leaf meal was found to be a useful additive in dietary supplements for laying hens (Montilla et al. 1974). *G. sepium* leaf meal

was found to have the following amino acid composition: threonine 1.2 %, valine 1.60 %, cysteine 0.39 %, methionine 0.42 %, isoleucine 1.20 %, leucine 2.41 %, tyrosine 1.12 %, phenylalanine 1.54 %, lysine 1.12 %, histidine 0.51 % and arginine 1.59 % (Chadhokar 1982). *G. sepium* leaf meal was found to have the following amino acid composition: threonine 1.2 %, valine 1.60 %, cysteine 0.39 %, methionine 0.42 %, isoleucine 1.20 %, leucine 2.41 %, tyrosine 1.12 %, phenylalanine 1.54 %, lysine 1.12 %, histidine 0.51 % and arginine 1.59 % (Chadhokar 1982). *G. sepium* leaves were found to contain condensed tannins (CT) which were all bound to proteins (Jackson et al. 1996). *Gliricidia sepium*, *Acacia boliviana*, *Arachis pintoi*, *Centrosema latidens* and *Senna velutina* contained <55 g total CT/kg DM, suggesting that they could comprise a reasonable proportion of ruminant diets. All other species grown in South America contained 100–240 g CT/kg DM, suggesting that they should only be fed in small amounts as supplements to dilute the CT concentration.

Studies showed that gliricidia leaf mulch had immense potential as green manure to improve productivity in tropical soils (Bah and Rahman 2001). Surface-applied gliricidia leaves significantly increased N uptake by maize and supplied >30 % of the total N in the stover and >20 % of that in the corn grain, even in the presence of hedgerows. The leaves also provide useful mulch material. Leaves are placed on bananas in containers to hasten ripening. Gliricidia has been planted to reforest and ameliorate denuded areas and reduce soil erosion, as windbreaks and firebreaks. It is widely cultivated as shade trees for cocoa, coffee and tea, and yams and also as live support trees for pepper and vanilla and as an understory crop in coconut plantations and in alley farming. It yields timber which is hard, heavy, durable, strong, coarse structured, easily worked and polished and is resistant to termites and rots. The wood is widely used for railway ties, posts, heavy construction, furniture, farm implements, tool handles and small articles. The wood is a useful source of fuel-wood. Studies found that *G. sepium* wood ash could be formulated with cement for concrete ad mixture

as construction material for low-cost housing (Aman et al. 2009).

Various parts of the tree have reported to have pesticidal properties. The toxic seeds, bark, leaves and roots are used as rodenticide to poison rodents (Uphof 1968). In the Philippines, branches are strewn in rice fields to help deter rice pest such as caseworm (*Nymphula* sp.) and whorl maggot (*Hydrellia* sp.) (Litsinger et al. 1978). Farmers in Latin America often bathe their livestock with a paste made of crushed *G. sepium* leaves to ward off tarsalos (American Warble fly). In the Philippines, the extract obtained from its leaves is used to remove external parasites such as fleas and ticks from cattle and dogs (Palacpac-Alo 1990). Water leaf extract of *Gliricidia sepium* was found to be toxic against *Microcerotermes losbanosensis* (Fernandez et al. 1989). The bioactive principle was identified as coumarin (Rabena 2007). Bioassay against termites (*Macrocerotermes losbanosensis*) manifested 95 % mortality (4 hours) and 100 % (8 hours) using 0.02 g/ml coumarin impregnated in filter paper in a Petri dish. However, the bioassay of crude water-soluble *Gliricidia* extract showed 75 % mortality (24 hours).

Gliricidia leaves were found to have acaricidal activity (Sivira et al. 2011; Alvarez et al. 2008). *Tetranychus cinnabarinus* oviposition decreased at a rate of 43.7 % or 57 % when 5 % oregano or *gliricidia* extracts were used, respectively. Also, 10 % oregano or *gliricidia* extracts caused 42.2 % or 72.5 % mortality of *T. cinnabarinus*, respectively. The presence of alkaloids, flavonoids, phenols and tannins, essential oils and saponins was verified in the plant material used. *Gliricidia sepium* was one of several plant species whose aqueous alcoholic extract exhibited marked inhibition on oviposition of the tick, *Boophilus microplus* (Alvarez et al. 2008). The ethanol leaf extract of *G. sepium* exhibited nematocidal activity against *Meloidogyne incognita* causing 60 % mortality (Nazli et al. 2008).

Comments

The tree is easily propagated by using stem cuttings.

Hardenbergia violacea

Scientific Name

Hardenbergia violacea (Schneev.) Stearn

Synonyms

Glycine violacea Schneev., *Hardenbergia monophylla* (Vent.) Benth., *Kennedia monphylla* Vent.

Family

Fabaceae.

Common/English Names

Climbing Morning Glory, False Sarsaparilla, Happy Wanderer, Native Lilac, Purple Coral, Purple Coral Pea, Native Sarsaparilla, Native Woodrose, Purple Twining Pea, Sarsaparilla.

Vernacular Names

Australia: Waraburra (Kattang Aborigines)

United States: Lilac Vine, Mexican Lilac Vine

Origin/Distribution

The species is native to Australia, growing in areas from Queensland to Tasmania. It has been introduced to the United States where it is grown as landscape plants.

Agroecology

In Australia the species is found in many habitats, growing widespread along the coast and adjacent ranges in the eastern and southern states on the mainland. It grows in coastal heath and forest and inland in drier eucalypt forests. In Tasmania, it is deemed as endangered, as it is only known from two small natural populations, on private land.

The species is moderately frost tolerant down to 0 to −5 °C and moderately drought tolerant. It thrives in areas with 400–2,400 mm mean annual rainfall in summer or winter, mean annual temperature range of 10–21 °C, and tolerates a summer maximum of 33 °C. It grows best in full sun but tolerates light shade in well-drained acidic (<pH 6.5) clay loam, loam, sandy loam or sandy clay loam soils. It is intolerant of salinity.

Edible Plant Parts and Uses

The leaves are boiled and used to prepare a sweet and pleasant beverage (Cribb and Cribb 1976; Kunkel 1984; Facciola 1990). The roots were also reportedly used in a similar way. The purple flowers are also eaten (Haslam 2011).

Botany

A hardy, evergreen, climbing or prostrate, glabrous subshrub with slender, woody stem growing to 2 m long. Leaf simple, ovate-narrow-lanceolate 3–10 cm by 1–5 cm wide, glabrous, dark green above, grey green beneath, leathery, margin entire, venation distinctly reticulate, tip mucronate, base rounded to indented (Plates 1 and 2), petiole 0.5–3 cm long, stipels 1–2 mm long, filiform. Inflorescence axillary, racemose panicle with 20–30 violet or reddish flowers, each axillary unit of 3 flowers with a subtending bract. Calyx 3–4 mm long with two dorsal sepals fully and the rest joined $\frac{3}{4}$ length; corolla 8 mm long, with violet purple (or red) standard with 2 yellowish white spots at the base, lateral wings on long yellow

claw, violet purple and keel also violet purple or red (Plates 1, 2 and 3); stamens 9 joined into a tube and 1 free, diadelphous; ovary 3–3.5 mm long. Pod flattened oblong, 35–50 mm long, glabrous, dark brown to black. Seeds 4–8, reinform, 2.5–3 mm, olive green to brown, strophiolate.

Plate 2 Purple flowered variety

Plate 1 Flowers and foliage

Plate 3 Red-flowered variety

Nutritive/Medicinal Properties

Percentage distribution in *H. violacea* pods and seeds of mineral nutrients respectively were as follows: Na, 57.5 %, 42.5 %; Fe, 56.2 %, 43.8 %; K, 50 %, 50 %; Ca, 49.7 %, 50.3 %; Mn, 46.9 %, 53.1 %; Cl, 37.7 %, 62.3 %; Zn, 39.7 %, 60.3 %; Cu, 37.6 %, 62.4 %; S, 28.9 %, 71.15; Mg, 26.1 %, 73.9 %; N, 10 %, 90 %; and P, 5.7 %, 94.3 % (Hocking and Kortt 1987).

Concentrations (per g dry weight) of minerals in the elaiosome, testa and embryo of the seed were reported, respectively, as dry matter, 2.6 mg, 32.5 mg, 20.6 mg; N, 31.55 mg, 2.14 mg, 86.90 mg; P, 0.72 mg, 0.74 mg, 4.36 mg; K, 5.91 mg, 8.84 mg, 16.15 mg; S, 1.14 mg, 0.91 mg, 4.27 mg; Ca, 0.84 mg, 2.53 mg, 1.61 mg; Mg, 0.50 mg, 1.41 mg, 2.08 mg; Cl, 0.50 mg, 0.38 mg, 0.46 mg; Na, 145.0 µg, 200 µg, 102 µg; Fe, 38.4 µg, 34 µg, 55.2 µg; Zn, 18.4 µg, 26.1 µg, 58.7 µg; Mn, 53.6 µg, 45.7 µg, 23 µg; and Cu, 2.76 µg, 2 µg, 18.85 µg. The fatty acid compositions of elaiosomes and mature seeds were, respectively: lauric, (12:0) 0.13 %, 0; myristic, (14:0) 0.46 %, 0; palmitic, (16:0) 21.93 %, 12.1 %; palmitoleic, (16:1) 2.55 %, 0; stearic, (18:0) 5.26 %, 5.1 %; oleic, (18:0) 60.62 %, 23.2 %; linoleic, (18:2) 7.54 %, 55.9 %; g-linolenic, (18:3) and α-linolenic, (18:3) 1.22 %, 3.0 %; and elaidic acid, (20:0) 0.29 %, 0. The amino acid composition [nmol amino acid (per mg dry weight meal)] of elaiosomes and dehulled seeds were, respectively: lysine, 21, 28.8; histidine, 6.5, 10.3; arginine, 37.7, 24.0; aspartic acid, 49.9, 44.49; threonine, 15.3, 21.9; serine, 18.4, 29.6; glutamic acid, 30.8, 74.0; proline, 18.8, 23; glycine, 33.1, 43.2; alanine, 23.1, 31.2; half-cystine, 3.8, 6.3; valine, 17.3, 22.4; methionine, 2.6, 5.0; isoleucine, 15.5, 15.5; leucine, 28.1, 34.1; tyrosine, 11.1, 13.1; phenylalanine, 15.9, 17.7; and canavanine 4.0, 47.

As seen from the above, the seeds accumulated about 50 % of the dry matter of a mature fruit; over 90 % of its N and P content; 50–75 % of its K, Ca, Mn, Cl, S, Zn, Cu and Mg, but less than 50 % of its Fe and Na (Hocking and Kortt 1987). Seeds contained higher levels of most nutrients than pods. The testa comprised 60 % of

the dry matter content of a seed and contained the major proportion of its Ca, Mg, Cl, Na and Mn; the embryo contained most of the seed's contents of N, P, K, S, Zn and Cu. The elaiosomes had less than 5 % of the seed's dry matter and mineral nutrient content. The oil content of the elaiosome was 34 %, compared to 12 % for the embryo. Oleic acid made up over 60 % of the fatty acid content of elaiosome oil. Aspartic acid, arginine and glycine were the predominant amino acids in the elaiosome. The embryo contained 10 % of the non-protein antimetabolic amino acid, canavanine, the elaiosome only 1 %. The subunit protein compositions of the elaiosome and embryo were different. Earlier, Rivett et al. (1983) reported that *Hardenbergia violacea* had a chemical composition which may have the potential for human food. The fatty acid composition of the elaiosome was quite different from that of the dehulled seed (Rivett et al. 1983) in that the predominant fatty acid of the seed was linoleic acid versus oleic acid in the elaiosome.

Concentrations (per g dry weight) of minerals in the leaves at 94 days after flower anthesis were as follows: N, 27.95 mg; P, 0.87 mg; K, 12.10 mg; S, 1.64 mg; Ca, 9.40 mg; Mg, 1.93 mg; Na, 0.29 mg; Cl, 0.74 mg; Fe, 190 µg; Zn, 26.4 µg; Mn, 180.8 µg; and Cu, 7.8 µg (Hocking and Kortt 1987).

The plant has been reported to be used in bush medicine as a tonic drink (Cribb and Cribb 1976; Haslam 2011).

Other Uses

A grey-blue dye is obtained from the flowers (Cribb and Cribb 1982).

Comments

The plant is readily propagated from seeds.

Origin/Distribution

The species is native to South America and Central America but is now a pantropical weed.

Agroecology

In the warm, wet tropics, the species has naturalized as a weed in cultivated areas, along roadsides, in plantations, in cropping areas, in orchards, in lawns, in pastures and on wasteland and forming mats on the dry mud of river banks, at elevations from near sea level up to about 2,000 m elevation. The plant is found on a wide range of soil types but thrives on well-drained soils, even scalped or eroded subsoils and soils with low nutrient concentrations and water-logged soils. On coralline soils, iron chlorosis has been observed (Rachman 1999). The plant is tolerant to light shade but does not compete with tall vegetation or grow under forest canopies. This plant is spread mainly by seeds clinging to man and animals and the seeds can remain viable for many years.

Edible Plant Parts and Uses

Flowers are crystallized or used for the preparation of distilled flower water (Crowhurst 1972; Facciola 1990).

Botany

Mimosa pudica is a low sprawling, prickly, 15–40 cm, branched annual or perennial, that may grow into a 70–100 cm prickly sub-shrub. The leaves are very sensitive to touch, alternate, green, compound, digitately bipinnate with 1–2 pairs of pinna and 10–20 pairs of leaflets per pinna (Plate 1). Each leaflet is 0.6–1.2 cm long by 0.3–0.4 cm broad, sessile, narrowly oblong or linear oblong; obliquely rounded at base, acute tip, nearly glabrous and lack prickles. The flowers are produced in globose head borne on a bristly or prickly peduncle (Plate 1). Flowers pink or mauve, 4-merous, subtended by linear, marginally setose bracteoles; calyx minute; corolla glabrous or with puberulous, ovate-oblong lobes; stamens 4 exerted; ovary sessile. Fruit is a lomentum, simple, dry, flat, slightly curved, 1.5–1.8 cm by 0.4–0.5 cm, bristly along the margins, with 2–5 segments that break up at the

Plate 1 Globose flower head, foliage and prickly stems

sutures. Seeds subcircular to elliptic, pale-brown, flat, 2.5–3 mm across.

Nutritive/Medicinal Properties

Plant (Aerial Parts) Phytochemicals

A non-protein amino acid leucine, mimosine, was isolated from *M. pudica* (Renz 1936) and its structure determined as 3-hydroxy- α -amino-4-oxo-1 (4H)-pyridinepropionic acid (Kleipool and Wibaut 1950). The same compound had been called leucenol. Serine and α -amino adipic acid precursors of mimosine, pipercolic acid and 5-hydroxypipercolic acid, were found in *Mimosa pudica* (Tiwari et al. 1967). Norepinephrine was isolated from the plant (Applewhite 1973).

Two C-glycosylflavones, 2'-*O*-rhamnosyl-orientin and 2'-*O*-rhamnosylisoorietnin, were isolated from the aerial parts (Englert et al. 1994). Two C-glycosylflavones 4''-hydroxymaysin and cassiaoccidentalin B and myricetin were isolated from the aerial plant parts (Lobstein et al. 2002). Flavonoids found in *M. pudica* included orientin, kaempferol 7-rutinoside and kaempferol 3-glucoside-7-rhamnoside (Yusof et al. 2003).

Four compounds were isolated from *M. pudica* and identified as 7, 8, 3', 4'-tetrahydroxyl-6-C-[α -L-rhamnopyranosyl-(1 \rightarrow 2)]- β -D-glucopyranosyl flavone (I); 5, 7, 4'-trihydroxyl-8-C-[α -L-rhamnopyranosyl-(1 \rightarrow 2)]- β -D-glucopyranosyl flavone (II); 5, 7, 3', 4'-tetrahydroxyl-6-C-[α -L-rhamnopyranosyl-(1 \rightarrow 2)]- β -D-glucopyranosyl flavone

(III); and catcher (IV) (Yuan et al. 2006). C-glycosylflavones were isolated from the whole plant of *Mimosa pudica*, and their structures elucidated as 5, 7, 3', 4'-tetrahydroxy-6-C-[β -D-apiose-(1 \rightarrow 4)]- β -D-glucopyranosyl flavone and 5, 7, 4'-trihydroxy-8-C- β -D-glucopyranosyl flavones (Yuan et al. 2007a) and 6, 7, 3', 4'-tetrahydroxy-8-C-[α -L-rhamnopyranosyl-(1 \rightarrow 2)]- β -D-glucopyranosyl flavones and, 5, 7, 3', 4'-tetrahydroxy-8-C-[β -D-apiose-(1 \rightarrow 4)]- β -D-glucopyranosyl flavone (Yuan et al. 2007b). Crocetin dimethyl ester and tannin have been isolated from the plant. The mucilage from seed was composed of D-xylose and D-glucuronic acid 4-O-(3,5-dihydroxybenzoic acid)- β -D-glucuronide. Mimosine, α -spinasterol and phenyl ethylamine derivatives were isolated from the plant (Muthumani et al. 2012).

Leaf Phytochemicals

M. pudica pulvinus was found to contain adenosine triphosphatase; the molecular weight of purified Ca, Mg-ATPase, was determined to be 139,000, and it played a role in the seismonastic movements of the leaf (Liubimova-Engel'gardt et al. 1978). Actin-like protein was found in the leaves (Ghosh et al. 1987). From *Mimosa pudica* fresh leaves and pulvinar callus cells, tubulin protein was isolated and purified (Pal et al. 1990). The purified protein consisted of alpha and beta subunits and trace quantities of other proteins. This protein constituted 5–6 % of the total extractable protein in the leaves. They postulated that movement of the leaves of this plant may be regulated by the presence of a high amount of this protein. Turgorin, the periodic leaf movement factor 1 (PLMF-1) (gallic acid β -D-glucopyranosyl-6'-sulphate), and sulphotransferase, the enzyme involved in sulphation of the turgorin, were found to be localized in the pulvinus of *M. pudica* plant (Varin et al. 1997). The pulvinus was also found to have annexin which may also have contributed to the nyctinastic movement in the pulvinus (Hoshino et al. 2004). The amount of annexin in the pulvinus increased at night and was sensitive to abscisic acid. Two

tonoplast proteins, a putative water-channel protein (aquaporin belonging to the [gamma]-TIPs [tonoplast intrinsic proteins]) and the catalytic A-subunit of H⁺-ATPase, were found in the mature motor cell in the leaves (Fleurat-Lessard et al. 1997). [Gamma]-TIP aquaporin was detected almost exclusively in the tonoplast of the colloidal vacuole, and the H⁺-ATPase was also mainly localized in the membrane of the same vacuole. *M. indica* was found to contain a gelsolin/fragmin family actin-modulating protein that severed actin filament in a Ca²⁺-dependent manner (Yamashiro et al. 2001). Kanzawa et al. (2006) found that changes in actin isoforms, fragmentation of actin filaments and the leaf bending movement were all inhibited after injection of a tyrosine phosphatase inhibitor. On this basis they propose that the phosphorylation status of actin at tyrosine residues affected the dynamic reorganization of actin filaments and caused seismonastic movement.

The cerebroside fraction of lipids of both the leaves and chloroplasts of *M. pudica* was found to contain a polyunsaturated fatty acid (20:4 ω 3) and a long-chain sphingosine base (Choudhury and Chakrabarti 1980). A phenolic ketone, 4-(24'-methoxy-24'-methyl-1'-oxo-5'-n-propyl-tetracosanyl)-phenol, was isolated from the leaves (Josewin et al. 1999).

A 5-deoxyflavonol derivative identified as 7,3,4-trihydroxy-3,8-dimethoxy flavone and *p*-coumaric acid were isolated from the leaves (Kirk et al. 2003).

Flower Phytochemicals

Flavonoids identified in pollens: isoquercetin, quercetin and isorhamnetin were most commonly found; other less commonly found in decreasing frequency were kaempferol, myricetin, tricetin and luteolin (Freire et al. 2012).

Seed Phytochemicals

A saponin (Jiang et al. 1990) and a novel bufadienolide, hellebrigenin-3-O- α -L-rhamno-

pyranosyl-(1 → 4)-*O*-β-D-galactopyranoside, from the seeds of *Mimosa pudica* (Yadava and Yadav 2001). The mucilage from seed was reported to compose of D-xylose and D-glucuronic acid 4-*O*-(3,5-dihydroxybenzoic acid)-β-D-glucuronide (Chatterjee and Pakrashi 2006). *Mimosa* mucilage was found to contain yellowish-brown and odourless flakes, which hydrate rapidly on contact with water to swell but is sparingly soluble in water (Singh et al. 2009). The pH of 1 % (wt/vol) aqueous dispersion of the mucilage was found to be 6.0–6.5. The swelling index of mucilage was found to be 81.77 % (vol/vol). The mucilage showed a loss on drying of 6.8 % (wt/wt) and yielded 0.106 % (wt/wt) of water-soluble extractive; the total ash contents were found to be 86.75 % (wt/wt); water-soluble ash and acid-insoluble ash were 61 and 7.5 % (wt/wt), respectively.

M. pudica seed oil extract was found to contain amino acids and derivatives: D-alanine, N-DL-alanylglycine, DL-alanine ethyl ester, DL-alanyl-DL-valine, 1-alanine ethyl amide; fatty acid derivatives: 9, 12-octadecadienoic acid (Z, Z), methyl ester; 9, 12-octadecadienoic acid, methyl ester; 11, 13-eicosadienoic acid, methyl ester, carbohydrate derivatives: meglumine; 1, 3-dioxolane-4-methanol; other compounds: methylamino-N-phenyl-acetamide; 1-butanamine, N-methyl; 2-methylamino-N-phenyl acetamide; 1-alanine ethylamide (S); 1-octamine, N-methyl; and 2, 5-dimethoxy-4-(methylsulphonyl) amphetamine (Saraswat and Pokharkar 2012).

Root Phytochemicals

One new sterolglucoside characterized as 4- α ,24-dimethylcholest-7-en-3 β -ol-3 β -D-glucoside along with stigmasterol, β -sitosterol and betulinic acid isolated from the roots (Dinda et al. 2006). The proximate analysis of *M. pudica* roots revealed values for total ash 17.365 %, water-soluble ash 9.65 %, alcohol-soluble ash 4.55 %, loss on drying 2.55 %, moisture content 0.58–5 %, foreign organic matter 0.5 % and sulphated ash 3.78 % (Pande and Pathak 2010). The petroleum ether fraction was found to contain

flavonoids, phytosterol, alkaloids, amino acids. Flavonoids were found in the acetone fraction and alkaloids in the chloroform fraction.

According to the Herbal Medicine Research Center, Malaysia (2002), the plant is believed to have diuretic, antiviral, antibacterial, anti-inflammatory, antispasmodic and hypoglycaemic properties. These and other pharmacological properties of the plant have been reported in in-vitro and some in-vivo animal studies.

Antioxidant Activity

The dichloromethane and methanol extracts of both *M. pudica* and *M. rubicaulis* showed prominent antioxidant property, with the RC_{50} values ranging from 4.70×10^{-1} to 2.10×10^{-2} mg/ml (Genest et al. 2008). The dichloromethane and methanol extracts of both *M. pudica* and *M. rubicaulis* showed prominent antioxidant property, with the RC_{50} values ranging from 4.70×10^{-1} to 2.10×10^{-2} mg/ml (Genest et al. 2008). The sequence of antioxidant activity of the ethanol extracts of *M. pudica* was as follows: leaf > the whole plant > seed > stem (Zhang et al. 2011). Leaf extracts of *M. pudica* contained the highest amount of total flavonoid and total phenolic, significantly higher than in other parts of the plant. The antioxidant sequence of the 5 flavonoid monomers was 5, 7, 3', 4'-tetrahydroxy-6-C-[β-D-apiose-(1 → 4)]-β-D-glycopyranosyl flavone (1) > isorientin (2) > orientin (3) > isovitexin (4) > vitexin (5), and the antioxidant activity of compound 1 was equivalent to the synthetic antioxidant trolox or a bit stronger than trolox, and significant correlations were found among the active ingredient contents and the results of antioxidant activity.

Antiinflammatory Activity

The ethanol and aqueous leaf extracts of *M. pudica* exhibited significant dose-dependent antiinflammatory activity in the carrageenan-induced paw oedema and cotton pellet tests in

rats while the petroleum ether extract exhibited minimum effect (Goli et al. 2011). The ethanol extract of dried, powdered *M. pudica* plant significantly inhibited the HMC-1 cell migration induced by stem cell factor and blocked the release of monocyte chemotactic protein-1 (MCP-1) and interleukin-6 (IL-6) in EoL-1 cells in BALB/c mice with asthma induced by ovalbumin (Yang et al. 2011). Leukocytosis, eosinophilia and mucus hypersecretion in asthmatic lung were significantly suppressed by mimosa extract. The release of ovalbumin-specific IgE in bronchoalveolar lavage fluid and serum was also decreased. The extract treatment resulted in no liver cytotoxicity. The results suggested that *M. pudica* extract had inhibitory properties on asthma and may be used as a potent therapeutic agent for allergic lung inflammation.

Anticonvulsant Activity

The decoction of *Mimosa pudica* leaf decoction administered intraperitoneally at dose of 1,000–4,000 mg/kg protected mice against pentylenetetrazol- and strychnine-induced seizures (Bum et al. 2004). It also antagonized N-methyl-D-aspartate-induced turning behaviour. These properties could explain its use in African traditional medicine.

Antiulcerogenic Activity

The methanolic leaf extract of *M. pudica* was found to possess remarkable ulcer-protective properties at 100 and 200 mg/kg in the aspirin-induced ulcer model in rats when compared to the other chloroform and diethyl ether extracts (Vinothapooshan and Sundar 2010). Pretreatment of rats with *Mimosa pudica* leaf extracts produced a dose-dependent protection in the ethanol-induced ulceration model as compared to control group. The methanolic, chloroform and diethyl ether extracts in doses of 100 and 200 mg/kg produced a reduction in the ulcer index, gastric volume, free acidity, total acidity and raised gastric pH significantly in comparison with control rats. The control animals had ulcers and haemorrhagic

streaks, whereas in animals administered with the extracts of *Mimosa pudica*, there was significant reduction in the ulcer index.

Hepatoprotective Activity

Methanolic leaf extract of *M. pudica* showed significant hepatoprotective effect against carbon tetrachloride-induced toxicity Wistar albino rats by lowering the serum levels of various biochemical parameters such as serum glutamic oxaloacetate transaminase (SGOT), serum glutamic pyruvates transaminase (SGPT), alkaline phosphatase (ALP), total bilirubin (TBL) and total cholesterol and by increasing the levels of total protein and albumin (Rajendran et al. 2009). These biochemical observations were in turn confirmed by histopathological examinations of liver sections and were comparable with the standard hepatoprotective drug silymarin (100 mg/kg body weight i.p.) which served as a positive control. Simultaneous administration of the aqueous leaf extract of *Mimosa pudica* along with the toxin ethanol in rats showed a considerable protection against the toxin-induced oxidative stress and liver damage as evidence by a significant increase in superoxide dismutase (SOD) catalase (CAT), glutathione peroxidase and glutathione levels (Nazeema and Brindha 2009). The study revealed that the co-administration of *Mimosa pudica* aqueous extract significantly lowered the level of lipid peroxidation in alcohol-fed mice.

Anticancer Activity

Mimosine, an iron chelator, was found to have potent cytotoxic and antiproliferative effects on human (CaOV-3 & OvCAR) and rat (NuTu 19) ovarian cancer cells in-vitro (Restivo et al. 2005). Iron challenge studies indicated that the antiproliferative effect of mimosine was mediated by iron chelation. Further, mimosine-induced apoptosis was confirmed by DNA fragmentation analysis.

The alkaloid fractions of the ethanol extracts of *Ervatamia coronaria* and *M. pudica* showed significant cytotoxicity with LC₅₀ values of 65.83

and 85.10 µg/ml in the brine shrimp lethality bio-assay, respectively (Hullatti et al. 2013).

Antiphidic Activity

The aqueous root extract of *M. pudica*, particularly the normal water extract, displayed a significant inhibitory effect on the lethality, myotoxicity and tested enzyme activities of *Naja kaouthia* venom compared with alcoholic root extracts (Mahanta and Mukherjee 2001). The aqueous root extract of *Mimosa pudica* dose dependently inhibited the hyaluronidase and protease activities of Indian snakes (*Naja naja*, *Vipera russelli* and *Echis carinatus*) venom (Girish et al. 2004). The water extract of *Mimosa pudica* showed 100 % ability in neutralizing the 2LD₅₀ lethality of *Naja naja kaouthia* venom (Vejayan et al. 2007). *M. pudica* also exhibited >50 % ability in neutralizing the 2LD₅₀ toxicity of venoms of other snakes, namely, *Ophiophagus hannah*, *Bungarus candidus*, *B. fasciatus* and *Calloselasma rhodostoma*. Aqueous extract of *Mimosa pudica* dried roots displayed significant inhibitory effect on the lethality, phospholipase activity, oedema-forming activity, fibrinolytic activity and haemorrhagic activity of venoms of *Naja naja* and *Bungarus caeruleus* (Meenatchisundaram et al. 2009). About 0.14 and 0.16 mg of *M. pudica* extracts were able to completely neutralize the lethal activity of 2LD₅₀ of *Naja naja* and *Bungarus caeruleus* venoms, respectively.

Mimosa pudica tannin isolate (MPT) obtained from the root exhibited promising in-vitro activity in neutralizing *Naja kaouthia* venom, but MPT injected into mice preincubated with the *Naja kaouthia* venom showed no in-vivo protection against the venom (0.875 mg/kg) in four different rescue modes (Ambikabothly et al. 2011). In contrast in another study, preincubation of 2LD₅₀ (1.84 mg/kg) of *Naja kaouthia* venom with *M. pudica* tannins was able to completely neutralize the snake venom since the survival rate of mice was 100 % after 24 hours of observation (Sia et al. 2011). In the mouse group in which there was no preincubation, no protection against the

effects of the venom was observed. Preincubation of the venom with commercial tannic acid showed only a mouse survival rate of 12.5 %. Tannins obtained from *M. pudica* were eight times more effective in neutralizing the lethal effects of *N. kaouthia* venom compared to the tannic acid.

Antimicrobial Activity

The dichloromethane and methanol extracts of *M. pudica* displayed considerable bacteriostatic activity against all six bacterial strains (MIC range=0.625–2.50 mg/ml) including *Bacillus cereus*, *B. subtilis*, *Escherichia coli*, ampicillin-resistant *Escherichia coli*, *Staphylococcus aureus* and *Pseudomonas aeruginosa* (Genest et al. 2008).

Organic extracts (ethanol, petroleum ether and chloroform) of *Mimosa pudica* exhibited antibacterial properties against Gram-positive (*Staphylococcus aureus*, *Bacillus cereus*, *Bacillus subtilis*, *Bacillus megaterium*) and Gram-negative (*Shigella shiga*, *Shigella dysenteriae*, *Klebsiella pneumoniae*, *Salmonella typhi*, *Pseudomonas aeruginosa*), human pathogenic bacteria (Akter et al. 2010). *M. pudica* extract was found to have antimicrobial activity against *Aspergillus fumigatus*, *Citrobacter divergens* and *Klebsiella pneumonia* (Gandhiraja et al. 2009). Ethanolic leaf extract showed antimicrobial activity against *Bacillus subtilis*, *Pseudomonas aeruginosa*, *Klebsiella pneumoniae*, *Aspergillus flavus* and *Trichophyton rubrum* (Tamilarasi and Ananthi 2012).

Anxiolytic Activity

Aqueous leaf extract of *M. pudica* was found to have antidepressant-like profile similar to two tricyclic antidepressants, clomipramine and desipramine (Molina et al. 1999). *M. pudica* (6.0 and 8.0 mg/kg, I.R) reduced immobility in the forced swimming test and increased the rate of reinforcers received in the differential reinforcement of low rates of response at 72 second test; the data suggested that *M. pudica* exerted antidepressant effects in the rat.

Wound Healing Activity

Treatment of wounds with ointment containing 2 % (w/w) methanolic and 2 % (w/w) aqueous extract of *M. pudica* roots exhibited significant wound healing activity in three types of model in rats, namely, excision, incision and estimation of biochemical parameter (Kokane et al. 2009). The methanolic extracts of *M. pudica* shoot and roots showed marked wound healing activity when compared to the standard drug gentamicin, but the chloroform root extract exhibited negative result (Kannan et al. 2009). In the incision, excision and burn wound models in rats, chloroform and methanolic extracts of *Mimosa pudica* roots at high as well as low doses demonstrated significant reduction in wound contraction and period of epithelialization compared to control (Paul et al. 2010). In the incision wound model, a significant rise in breaking strength was observed in all treated group animals. Both extracts produced a significant increase in the breaking strength, dry weight and hydroxyproline content of the granulation tissue in dead space wound model. The results suggested that both extracts applied topically or administered orally possess wound healing activity.

Antiobesity/Hypolipidaemic Activity

In hyperlipidaemic rats, chloroform leaf extract of *M. pudica* showed significant hypolipidaemic effect by significantly lowering the serum levels of biochemical parameters such as serum cholesterol, triglyceride, LDL and VLDL and increasing in HDL level which was similar to the standard drug Atorvastatin (Rajendran and Krishnakumar 2010). These biochemical observations were in turn confirmed by histopathological examinations of aorta, liver and kidney sections.

Quercetin [-2-(3, 4-dihydroxyphenyl)-3, 5, 7-trihydroxychromen-4-one], a flavonol present in *Mimosa pudica*, was found to antagonize peripheral hypothalamic cannabinoid-1 (CB1) receptor involved in the regulation of appetite, lipogenesis and insulin resistance (Shrinivasan

et al. 2012). The docking of quercetin with CB1 receptor showed a binding energy of -6.56 Kcal/mol with four hydrogen bonds in comparison to the known drug Rimonabant. The blocking of CB1 receptor could reduce body weight and improve cardiometabolic abnormalities in experimental and human obesity.

Hypoglycaemic Activity

The alcoholic, petroleum-water extracts of dried whole plants and the isolated quaternary alkaloids were found to lower blood glucose level in diabetic rats, beginning 2 hours following oral administration and peaking after 6 hours (Dechatiwong et al. 1988). The ethanolic *M. indica* leaf extract significantly decreases blood glucose level in alloxan-induced diabetic rats (Sutar et al. 2009). Another study found that significant reduction in fasting blood glucose (FBG) levels of the normoglycaemic mice was observed at 4 and 3 hours with plant extracts of *Mimosa pudica* (200 mg/kg bw) and *Rauwolfia serpentina* (100 mg/kg bw) (Manosroi et al. 2011). In alloxan-induced diabetic mice, all extracts showed significant hypoglycaemic activity.

‘Illogen-Excel’, an Ayurvedic herbal formulation composed of eight medicinal plants (*Curcuma longa*, *Strychnos potatorum*, *Salacia oblonga*, *Tinospora cordifolia*, *Vetiveria zizanioides*, *Coscinium fenestratum*, *Andrographis paniculata* and *Mimosa pudica*) exhibited anti-hyperglycaemic effect in streptozotocin-induced diabetic rats (Umamaheswari and Mainzen Prince 2007). It significantly lowered levels of blood glucose glycosylated haemoglobin, plasma thiobarbituric acid reactive substances, hydroperoxides, ceruloplasmin and vitamin E in diabetic rats and significantly increased levels of plasma insulin, hepatic glycogen and total haemoglobin.

Hyperglycaemic Activity

Ethanolic extract of *Mimosa pudica* leaves given by oral route to mice at a dose of 250 mg/kg

exerted a significant hyperglycaemic effect (Amalraj and Ignacimuthu 2002).

Antinociceptive Activity

In the acetic acid-induced writhing animal model, the aqueous extract of *Mimosa pudica* at a dose of 200 and 400 mg/kg body weight showed significant inhibition of writhing response of 46.24 and 56.0 %, respectively. In the hot plate test, the extract produced a significant increase in the latency in a dose-related manner. This study confirmed the analgesic properties of *Mimosa pudica*.

Antispasmodic Activity

The total alkaloidal extract of *M. pudica* roots antagonized the contractions of the isolated guinea pig ileum induced by histamine hydrochloride and acetylcholine (Quashem et al. 1977).

Anxiolytic and Antipyretic Activities

In stress-induced hyperthermia test, *M. pudica* at the dose of 180 mg/kg exhibited antipyretic activity; it significantly prevented the increase of temperature in mice (Bum et al. 2011). In the elevated plus maze test, *M. pudica* also reduced the percentage of mice entries and time in closed arms, indicating its anxiolytic-like property. Acute treatment with *M. pudica* extract had an anxiolytic effect on mouse behaviour in the elevated T maze, specifically on inhibitory avoidance behaviour (Mbomo et al. 2012). The extract alone had no effect on the activity of DRN 5-HT neurons. However, when co-applied with the GABA(A) receptor agonist THIP (4,5,6,7-tetrahydroisoxazolo[5,4-c]pyridin-3-ol), the extract enhanced the inhibitory effect of the THIP on DRN 5-HT neurons. The study suggested that the aqueous extract of *M. pudica* contained a positive modulator of GABA(A) receptor function.

Treatment for Uterine Prolapse

Shivanandaiah and Indudhar (2010) found *Mimosa pudica* to be useful in cases of uterine prolapse with bleeding, based on their experience of working with the condition for more than 45 years and treating hundreds of such cases of uterine prolapse. Hysterectomy had been avoided thus far.

Hair Growth Inhibition Activity

Mimosine was found to be responsible for hair loss in animals following ingestion of seeds and foliage of *Leucaena glauca* and in women after consumption of *Leucaena glauca* seeds (Crounse et al. 1962). The toxic principle contained in the plant was found to be a water-soluble amino acid termed leucenol, which was identical with mimosine obtained from *Mimosa pudica*. Mimosine appeared to be the preferred name for the compound, both by historical precedent, and to avoid confusion with leucinol, an alcoholic derivative of leucine.

Antifertility Activity

Mimosa pudica leaf extract exhibited antioestrogenic activity and anti-implantation effect in female albino rats (Devi et al. 2001). *Mimosa pudica* root powder (150 mg/kg bw), when administered intragastrically, altered the oestrous cycle pattern in female *Rattus norvegicus*. Nucleated and cornified cells were absent in all rats (Valsala and Karpagaganapathy 2002). There was a significant reduction in the number of normal ova in rats treated with the root powder compared with the control rats and a significant increase in the number of degenerated ova. Studies found that *M. pudica* root powder did not possess oestrogenic activity, as it did not cause an increase in uterine weight of immature female rats (Valsala and Karpagaganapathy 2002). It showed antioestrogenic activity by blocking the increase in uterine weight caused by administration of estradiol monobenzoate.

M. pudica root extract exhibited antifertility effect (Ganguly et al. 2007). It prolonged the estrous cycle and disturbed the secretion of gonadotropin hormones in albino mice. The decrease in follicle-stimulating hormone level in the proestrus and estrus stages in the extract-administered group compared with those of control animals indicated the disturbance of estrous cycle and ovulation through suppression of follicle-stimulating hormone.

Anthelmintic Activity

The methanol leaf extract of *M. pudica* was found to inactivate 50 % the roundworm *Strongyloides stercoralis* filariform larvae (causal agent of strongyloidiasis) in-vitro within an hour (Robinson et al. 1990). Studies indicated that the crude alcoholic extract and aqueous extracts of *M. pudica* significantly demonstrated paralysis and also caused death of test worms (*Pheretima posthuma*) in dose-dependent manner as compared to standard reference albendazole (Bendgude et al. 2012), while petroleum ether extracts showed weak anthelmintic effect.

Enzyme Inhibitory Activity

One of the phenyl ethylamine derivatives isolated from the plant exhibited amylase and urease inhibitory activity in-vitro (Muthumani et al. 2012).

Absence of Antiurolithiatic Activity

Studies in albino rats showed that *M. pudica* was not effective in either preventing stone deposition or dissolving preformed stones (Joymma et al. 1990).

Tablet Formulation Studies

Studies by Singh et al. (2009) found that *Mimosa* seed mucilage can be used as matrix-forming

agent for sustained drug delivery in tablet formulations. Studies by Ahuja et al. (2010) found that *Mimosa pudica* seed mucilage had potential as bucoadhesive polymer in the formulation of buccal discs. *Mimosa pudica* seed mucilage was found to be a potential tablet disintegrant and binder (Ahuja et al. 2013). The disintegration time of mucilage containing tablets was found to be in the order of 3 % > 1 % > 5 % > 7.5 % > 10 %. On comparative evaluation with standard disintegrants, it was observed that the order of disintegration of tablets was Ac-Di-Sol < mucilage (3 %, w/w) < corn starch. *Mimosa* mucilage at 10 % (w/w) concentration provided tablets with adequate hardness and friability.

Chromoblastomycosis Source

Robinson et al. (1990) reported a case of chromoblastomycosis in a patient. Clinical diagnosis of chromoblastomycosis was established by direct microscopic examination and cultures from the patient's lesion. The causal fungus, *Fonsecaea pedrosoi*, was isolated from the patient and from the thorns of *Mimosa pudica* plant. The data indicated that *M. pudica* could be a natural source of infection for the fungus *F. pedrosoi*.

Traditional Medicinal Uses

Mimosa pudica has been used traditionally for the treatment of insomnia, diarrhoea and inflammatory diseases (Yang et al. 2011). According to the Herbal Medicine Research Center, Malaysia (2002), the plant has been used to treat bronchitis, herpes, hernia, dysentery, menstrual problems, asthma and swellings and to purify blood. A decoction of the roots is believed to be useful for treating urinary infections. The roots mixed with other plant ingredients to make a tonic are taken for good health and vitality. In Malaysia, bits of the plant are placed under the sleeping mats of fretful child, which is believed to induce sleep, and twigs are sold for this purpose in Java (Burkill 1966). The Malays would bathe a fretful child in a plant decoction to cure insomnia and

apply pounded leaves as poultice for swellings. *Mimosa pudica* var. *hispida* has been traditionally used for the treatment of diabetes mellitus and other diseases for several generations by the Thai-Lanna people in the Northern part of Thailand (Manosroi et al. 2011); the plant is also used for insomnia in Thailand (Rachman 1999).

In Fiji, the plant is used to treat fever, syphilis, venereal disease, leprosy, insomnia, insect bites, nervousness and haemorrhoids and as a vermifuge (WHO 1998); the leaves are mixed with other plants and are used to treat urinary infections and haemorrhoids. In the Philippines, the leaves are soaked in coconut oil and placed on wounds and ulcers; the plant decoction is considered antiasthmatic, and the roots are used to treat dysentery and dysmenorrhoea and also used as a diuretic (de Padua et al. 1977). In Vietnam, the leaves are considered to be sedative, hypnotic in folkloric medicine and beneficial for people suffering from insomnia; a leaf infusion is used to treat febrile stiffness, and the roots are used to treat arthritis (Nguyen 1993). The seeds are used as emetic in Indo-China. In New Britain, Papua New Guinea, the roots and leaves have been used to treat swollen testicles, and in South America, the roots have been used to treat diarrhoea and dysentery and used as an emetic (Rachman 1999). Stuart (2012) reported that in Mexico and China, the plant is used for treatment of anxiety and depression, and the roots are used as vomitive in the Antilles, Guiana and La Reunion. *Mimosa pudica* has been reported to be used for childbirth and infertility in folkloric medicine in Trinidad and Tobago (Lans 2007).

In La Reunion, its stem, leaves and roots are mentioned as a calming remedy against sleepiness, spasms and convulsions of children (Lavergne and Vera (1989). *Mimosa pudica* is used in traditional medicine in Cameroon to treat insomnia, epilepsy, anxiety and agitation (Bum et al. 2011). In the Republic of the Congo (Congo-Brazzaville), the entire plant is pounded and rubbed onto people suffering pains in their body sides and kidneys (Burkill 1995). In Senegal, the leaves are employed for lumbago and nephritis. All parts of the plant have been utilized to treat glandular tumours and uterine cancer.

The herb has been used traditionally for ages in India in the treatment of urogenital disorders, piles, dysentery and sinus and also applied on wounds (Ahmad et al. 2012). The leaves are used for increasing the sexual potency in men in Kurukshetra District (Haryana), India; the leaves and roots are used for gravel and other kidney diseases, also for piles and fistula in the Sagar District, Madhya Pradesh, India, and the roots are used in an oral snakebite remedy (Ahmad et al. 2012). Remote communities in India use the plant for inflammation, diabetes, fever, pile and various diseases (Goli et al. 2011). The plant is useful in vitiated conditions of 'pitta', leucoderma, vaginopathy, metropathy, ulcers, dysentery, inflammations, burning sensation, haemorrhoids, jaundice, asthma, fistula, small pox, strangury, spasmodic, affections and fever. The leaves are bitter, sudorific and tonic and are useful in hydrocele, haemorrhoids, fistula, scrofula, conjunctivitis, cuts and wounds and haemorrhage. The whole plant is used internally for vesicle calculi and externally for oedema, myalgia rheumatism and tumours of the uterus (Sharma et al. 2001). The plant is also used in the treatment of sore gum and is used as a blood purifier (Ghani 2003). In Ayurvedic and Unani system of medicine, this plant has been used in diseases arising from corrupted blood and bile, bilious fever, piles, jaundice, leprosy, ulcers and small pox. *Mimosa pudica* is one of the folk medicinal plants commonly used as antifertility agent in some places in India (Ganguly et al. 2007). The roots of *M. pudica* have been used in folkloric medicine for temporary birth control in Assam (Tiwari et al. 1982). The Irula tribe of the Chittoor district of Andhra Pradesh uses the leaves for diabetes and filariasis and the roots for whooping cough (Vedavathy et al. 1997).

In Orissa (Kandhamal District) the warmed root paste is plastered with the help of a cloth on boils to get relief (Behera et al. 2006). The paste of root fried in castor oil is applied on deep cut wounds to stop bleeding and for healing. The paste of root fried in ghee is applied on caries teeth for relief from toothache. The warmed leaf paste is applied around furuncle, abscess and boils to the burst and release of pus and applied

on the burst boils and itches for quick healing. The leaf paste is applied on forehead to get relief from headache and migraine. The leaf paste with honey is prescribed twice a day in empty stomach for 3–4 days for stomachache and intestinal worms.

Other Uses

Young stems with soft prickles and leaves are useful as forage. It is also used as green manure and cover crop as in Thailand where it is used as ground cover on road verges. The plant contains tannin which can be used for the production of leather. In some countries, this plant is grown as an indoor ornamental annual or curiosity plant.

The plant has nematicidal activity. *M. pudica* seeds showed nematicidal activity against the second stage juvenile larvae of *Meloidogyne incognita* (Vijayalakshmi et al. 1979). The root extract at a dose of 300 ppm completely inhibited egg hatch of *M. incognita* and also significantly affected the infectivity and development of the larvae (Le and Davide 1979).

Comments

The plant has become an invasive species in many countries around the world in Asia, North and South America, Africa, Australia and the Pacific Islands. In Australia, the species has been declared a weed in the Northern Territory and Western Australia and a controlled weed in Queensland. The plant can also be a pest in tropical pastures where high plant populations and the sharp prickles restrict grazing.

Vietnam: Giáng Hương ǎn; Giáng Hương Mất Chim; Gióc; Huỳnh Bá Rừng

Yapese: Arau

Origin/Distribution

Pterocarpus indicus is native to Southeast Asia, northern Australasia and the western Pacific Ocean islands. According to Rojo (1972) its western limit is southern Myanmar, extending eastward to peninsular Thailand, Malaysia, Laos, Kampuchea to Vietnam and Taiwan, farther eastward reaching the Solomons in the Pacific via Sumatra, West Java, Borneo, Philippines, Sunda Islands, the Moluccas, New Guinea and the Pacific (Ryukyu, Carolines and Vanuatu).

Agroecology

A widespread tree found in lowland evergreen primary and some secondary forest from near sea level to 1,300 m elevation, mainly along tidal creeks and rocky shores (Corner 1988; Rojo and Alonzo 1994; Thomson 2006). It thrives in areas with mean annual temperatures of 22–32 °C and mean annual precipitation of 1,300–4,000 mm. It tolerates low temperatures down to 5–8 °C but is frost sensitive, and it is drought resistant. It grows best in full sun but will tolerate light shade (25 %). Angsana is adaptable to a wide range of soil types including infertile, alkaline, stony soils to deep, fertile, loamy, alluvial soils. It is most commonly found growing in well-drained, sandy to clay loams of slightly acid to slightly alkaline pH from pH of 4.0–7.5. According to Thomson (2006) narra is expected to be damaged (including some leaf scald and drop) by salt-laden winds

and is not recommended for planting in the most exposed seaside locations. However, it often occurs near to the sea and presumably has a moderate level of tolerance of foliar salt spray.

Edible Plant Parts and Uses

Both fragrant flowers and young leaves are eaten in Thailand (Burkill 1966).

Botany

A large, tall deciduous tree, 15–30 m high with high buttresses, greyish bark and a trunk diameter up to 2 m. Stipules caducous, linear and pubescent. Leaves imparipinnate, 12–22 cm long, with 5–11 leaflets, rachis and petiolule glabrescent (Plate 1). Leaflet ovate-elliptic, 4–5 by 6–10 cm, chartaceous to subcoriaceous; surfaces concolorous and glabrous, lateral veins 6–8 pairs, margin entire, base rounded, obtuse to acute, apex acuminate. Inflorescence laxly branched panicle (Plates 1 and 2), 10–18 cm long mostly axillary rarely terminal. Flowers few to numerous. Bracteoles 2, linear-oblong, at base of calyx. Calyx campanulate, 5–6 mm long, deltoid lobes hairy inside towards the top. Corolla yellow, petals long clawed; standard ovate-orbicular to oblong, 16–18 mm; wings oblong, as long as standard; keel narrowly oblong, smaller than wings. Stamens 10, diadelphous (9+1). Ovary shortly

Plate 1 Flowers and imparipinnate leaves

Plate 2 Laxly branched panicle with yellow flowers

stipitate, oblong, 7–8 mm, densely pubescent with two ovules. Style curved with minute stigma. Fruit orbicular or semiorbicular legume, brown to blackish, densely hairy, 4–6.6 cm across, shortly stalked and broadly winged around margin, wing to 2 cm wide. Seeds reniform, narrow and oblique 2–5 by 8–10 mm, smooth and brownish.

Nutritive/Medicinal Properties

Leaf Phytochemicals

A mixture of terpenoids, loliolide (>85 %) and paniculatadiol (<15 %) was obtained from the ethyl acetate leaf extract of *Pterocarpus indicus* (Ragasa et al. 2005).

Wood/Bark Phytochemicals

Pterocarpin and homoptercarpin were isolated from the red dye found in the hardwood of *P. indicus* and *P. santalinus* (Ryan and Fitzgerald 1912/1913). The following isoflavonoids were isolated from the heart wood: formononetin, isoliquiritigenin, (–)-*p*-hydroxyhydratropic acid, 2-arylbenzofuran, angolensin and pterocarpin (Cooke and Rae 1964). Pterocarpol and β-eudesmol were isolated from the heartwood (Parthasarathy and Seshadri 1965). Hager's Handbook (List and Horhammer 1969–1979) reported the presence of

pterocarpin and pterostilben homoptercarpin, prunetin (prunusetin), formononetin, isoliquiritigenin, *p*-hydroxyhydratropic acid, pterofuran, pterocarpol and β-eudesmol in the wood.

The bark had been reported to contain kino which exude out as sap when an incision is made on the bark (Burkill 1966). Its chief constituent is kinotannic (coccotannic) acid (Kress 1995–2013). The red sap exuding from incision of the bark afforded a kind of red crystal which was found to be a macromolecular compound of tannic condensation and glucoside (Wang et al. 1997). The wood also contains the red-colouring matters, narin and santalin, and angolensin (Duke 1983). Narin is a dark red amorphous powder which yields phloroglucinol and resorcinol on fusion with alkali. A nondialyzable polyphenolic substance, PI, molecular weight 20,400, with antiplasmin activity, was isolated from *Pterocarpus indicus* bark (Takeuchi et al. 1986a). An antifungal compound, β-eudesmol, a sesquiterpene alcohol, was isolated from the *n*-hexane solubles in methanolic extracts of amboyna wood by bioassay-guided fractionation using *Pleurotus pulmonarius*, a wood-rotting fungus (Kusuma et al. 2004). Fluorescence from the aqueous extract of the tropical hardwood *Pterocarpus indicus*, erstwhile known as *Lignum nephriticum*, was demonstrated (Muyskens and Vitz 2006).

Anticancer Activity

Studies showed that injection of an aqueous extract of *P. indicus* leaves significantly inhibited the growth of Ehrlich ascites carcinoma cells in mice (Endo and Miyazaki 1972). Of the extract treated group, 40/50 survived more than 84 days, whereas all mice in the control died within 21 days. The nuclei and cytoplasm of tumour cells became soft and larger and then disintegrated. The active principle was found to be an acidic polypeptide, consisting of 17 amino acids. The LD₅₀ in mice was 122 mg/kg i.p.

A polyphenolic substance, PI, from *P. indicus* bark, inhibited plasmin esterolytic activity at ED₅₀=2.5 μg/mL and also showed carcinostatic effect on mice bearing ascites Ehrlich carcinoma

at a dose of 2 mg/kg (Takeuchi et al. 1986a). Further, examination of PI effects on alteration of native and TPA (12-*O*-tetradecanoyl-phorbol-13-acetate)-induced in-vitro phenotypes revealed that PI suppressed both the plasmin and ODC (ornithine decarboxylase) activities of the cells that increased with spontaneous malignancy, and also the TPA-induced ODC activity increase (Takeuchi et al. 1986b). TPA-induced decrease of ¹²⁵I-mEGF (epidermal growth factor)-binding ability was reversed by PI, to larger extent in the HeLa cells than in the untransformed RME-5-3-1 cells.

Antimicrobial Activity

The petrol, dichloromethane, ethyl acetate, butanol and methanol fractions of *P. indicus* leaf, root and stem bark exhibited a wide spectrum of antibacterial activity (Khan and Omoloso 2003). The activity was more pronounced in the butanol and methanol fractions. None were active against moulds. β -Eudesmol, isolated from wood, inhibited growth of *Pleurotus pulmonarius*, a wood-rotting fungus in-vitro, in a concentration-dependent manner (Kusuma et al. 2004).

A mixture of terpenoids, loliolide and paniculadiol from the leaves exhibited in-vitro antimicrobial activity against *Candida albicans* and low activity against *Pseudomonas aeruginosa*, *Escherichia coli* and *Aspergillus niger* but was inactive against *Staphylococcus aureus*, *Bacillus subtilis* and *Trichophyton mentagrophytes* (Ragasa et al. 2005).

Wood contains the red-colouring matters, narin and santalin, and angolensin (Duke). Narin is a dark red amorphous powder which yields phloroglucinol and resorcinol on fusion with alkali. Hager's Handbook (List and Horhammer 1969–1979) reported the presence of pterocarpin and pterostilben homopterocarpin, prunetin (prunusetin), formononetin, isoliquiritigenin, *p*-hydroxyhydratropic acid, pterofuran, pterocarpol and β -eudesmol in the wood. Distilled wood gives a moderately heavy tar. Cups made from

the wood and chips of wood impart to water a beautiful blue and yellow colour, which changes in light and shadow (Little and Wadsworth 1964) fluorescent, and this odd response to light may have been associated with remedies.

Traditional Medicinal Uses

Kino is a well-known Malay medicine; it is used commonly for treating sores especially oral sores (Burkill 1966). In Java, Kino or a bark decoction is employed for thrush and to arrest diarrhoea. The young leaves are applied to ripening boils, ulcers and prickly heat. A leaf infusion is used as hair wash. Juice from the roots is used for syphilitic sores. Angsana wood is used as a folk remedy for stomach pains, sprue, palpitations of the heart, rheumatism, leucorrhoea, gravel and yaws. Burkill also reported that in Kampuchea, the wood is used for fevers and is considered as diuretic and antidyenteric. The red sap from its incision of the bark becomes a kind of red crystal after some hours of exposure to air, which is used as an astringent and against other diseases (Wang et al. 1997). According to Hartwell (1967–1971), the red latex is used in folk remedies for tumours, the plant for cancers, especially of the mouth. In the Carolyn Islands, finely powdered leaves are applied to a ruptured vagina.

Other Uses

P. indicus is widely planted as an avenue/road-side tree and as shade trees in car parks, gardens and parks in Southeast Asia. The flowers are a honey source. The reddish hard wood is an excellent timber and is listed among the most valuable timbers in the Philippines. The beautiful, termite-resistant, rose-scented reddish timber is marketed as Amboyna, Blanco's Narra, Burmese Rosewood, Malay Padauk, Narra, Philippine Mahogany, Prickly Narra and Tenasserim Mahogany. It is used for cabinetry, cart wheels, carvings, construction, floorings and musical instruments, and when finely sliced,

it produces an extremely decorative veneer, used for decoration and furniture. The tree also provides kino, a reddish dye narin, resin and gum used for tanning. The *n*-hexane extract from *P. indicus* heartwood exhibited active inhibition on the activities of the subterranean termite, *Coptotermes curvignathus* with MIC of 2 % (Brata et al. 1999).

Comments

P. indicus is the national tree of the Philippines as well as the provincial tree of Chonburi and Phuket in Thailand. It is very easily propagated from seed or large stem cuttings.

Senna alata

Scientific Name

Senna alata (L.) Roxb.

Synonyms

Cassia alata L. basionym, *Cassia alata* var. *perennis* Pamp., *Cassia alata* var. *rumphiana* DC., *Cassia bracteata* L. f., *Cassia herpetica* Jacq. (nom. illeg.), *Cassia rumphiana* (DC.) Bojer, *Herpetica alata* Cook & Collins, *Herpetica alata* (L.) Raf.

Family

Fabaceae also placed in Caesalpiniaceae

Common/English Names

Candelabra Bush, Candelabra Plant, Candle Bush, Candlestick Senna, Empress-Candle-plant, Emperor's Candlesticks, Christmas-Candle, Emperor's Candle Plant, Emperor's Candlesticks, Golden-Candle Senna, Golden Candelabra Tree, King-of-the-Forest, Ringworm Bush, Ringworm Plant, Ringworm Senna, Ringworm Bush, Ringworm Shrub, Roman Candle Tree, Seven Golden Candles, Seven-Golden-Candlesticks, Stick Senna, Winged Senna, Yellowtop

Yapese: Flay-N-Sabouw

Origin/Distribution

Senna alata is indigenous to tropical South America (French Guiana, Guyana, Surinam, Venezuela, Brazil and Colombia). It has been distributed globally and has naturalized in Central America, southeastern United States (Florida), tropical Africa, tropical Asia, the Caribbean and on several Pacific Islands (the Cook Islands, Fiji, Guam, Palau, Tonga, Western Samoa and Hawaii), Papua New Guinea and throughout northern and eastern Australia.

Agroecology

S. alata is found in diverse habitats: alongside waterways, rivers and drainage channels, margins of ponds and ditches, in open forest, coastal

plains, floodplains, wetlands, native bushland, disturbed sites, waste areas, roadsides, overgrazed pastures, orchards and around villages. However, it prefers open areas and sunny locations at low to medium altitude but can also be found up to 1,400 m altitude. It often forms thickets and is aggressive in areas where there is a high water table. It is reported to tolerate an annual rainfall of 600–4,300 mm and average annual temperatures of 15–30 °C and is frost sensitive. It grows on both heavy and sandy, acid to slightly alkaline, well-drained soils but thrives best in deep, well-drained soil rich in organic matter with a pH range of 5.5–6.5.

Edible Plant Parts and Uses

Flowers or leaves are edible after cooking and may be used as a laxative (Burkill 1966). The inflorescence are boiled with chilli and consumed for constipation (Monkheang et al. 2011). In Myanmar, fresh leaves and flowers are used as vegetables and in curries (Myanmar Department of Traditional Medicine 2008). In Sabah and Peninsular Malaysia, the young shoots are cooked and eaten as vegetable. Toasted leaves along with *Glycine* beans are sometimes made into a drink similar to coffee (Burkill 1966). Young immature pods are eaten in small quantities, raw or steamed in the Philippines (Pardo de Távora 1901).

Botany

Coarse, erect, branched shrub growing from 1.5 to 4 m tall; leaves to about 50–80 cm long, alternate, pinnate, with 8–14 pairs of large leaflets (the distal ones largest), up to 17 cm long, ovate-oblong, obtuse, truncate or even slightly notched at apex, margin entire, subsessile (Plates 1 and 2). The inflorescence is a long-pedunculate, erect, dense, oblong spike, terminal or axillary, 10–15 cm long, with overlapping and crowded yellow flowers, 4 cm in diameter. Flowers are enclosed within dark-yellow or orangey bracts which shed off during flower opening (Plate 1). Flower bisexual, zygomorphic

Plate 1 Terminal inflorescences and yellow flowers

Plate 2 Slender upright branches and pinnate leaves

and pentamerous, with 5 oblong sepals, 5 bright yellow ovate-orbicular petals (20 mm long by 12 wide), 10 stamens, 2 fertile with elongated anthers and 8 with rudimentary anthers; elongated recurved, pubescent ovary with short slender style and stigma. Pod is green, ripening brown to black, straight, papery in texture, winged, up to 15–20 cm long and slightly over 1 cm wide; seeds numerous (to 50), shiny, flat and triangular.

Nutritive/Medicinal Properties

Nutrient and Phytochemicals in the Leaves

Nutrient composition of the edible leaves per 100 g based on analyses carried out in Nigeria was reported as moisture 58.4 g, energy 159 kcal, protein 6.8 g, fat 0.6 g, carbohydrate 31.5 g, fibre

0.1 g, ash 1.8 g, vitamin A 52 µg RE, vitamin A 26 RAE µg, β-carotene 310 µg, thiamine 0.45 mg, riboflavin 0.58 mg, niacin 0.54 mg, folic acid 15 µg, vitamin C 7.74 mg, calcium 755 mg, phosphorus 739 mg, iron 14.8 mg and zinc 3.7 mg (CINE 2007).

Hauptmann and Nazario (1950) isolated rhein (1,8-dihydroxyanthraquinone-3-carboxylic acid) along with hydroxymethyl anthraquinones and chrysophanic acid from the alcoholic leaf extract. Physcione, kaempferol, rhein methyl ester diacetate and β-sitosterol (Rao et al. 1975); 1,3,8-trihydroxy-2-methylanthraquinone (aloe-emodin), chrysophanol, deoxycoelulatin, sennoside A, sennoside B, sennoside C and sennoside D (Mulchandani and Hassrajani 1975; Villaroya and Bernal-Santos 1976); aloe-emodin, rhein glycoside and aloe-emodin glycoside (Rai 1978); anthraquinones and anthracene derivatives of rhein, emodol, aloe-emodin, sennosides A and B, 4,5-dihydroxy-1-hydroxymethylanthrone and 4,5-dihydroxy-2-hydroxymethylanthrone (Fuzellier et al. 1982); aloe-emodin and chrysophanol (Harrison and Garro 1997), isochrysophanol and physcion-L-glucoside (Smith and Sadaquat 1979); rhein (cassic acid) (Palanichamy et al. 1991); and aloe-emodin (1,8-dihydroxy-3-(hydroxymethyl) anthraquinone), sitosterol and stigmasterol (Hofileña et al. 2000), 3,5,7,4'-tetrahydroxy flavone and 2,5,7,4'-tetrahydroxyisoflavone (Rahaman et al. 2006, 2008) were isolated from the leaves. Kaempferol-3-*O*-gentiobioside was the major flavonoid glycoside in *Senna alata* (Moriyama et al. 2003c). The mature leaf was found to contain the highest content of this metabolite. The contents ranged from 2.0 to 5.0 % and 1.0 to 4.0 % in mature and juvenile leaves, respectively. Kaempferol-3-*O*-gentiobioside was not detected in the seed. Earlier, Moriyama et al. (2001) reported the disappearance of kaempferol 3-gentiobioside in the sun-dried leaves, while there was little or no change in the kaempferol 3-gentiobioside concentration in the heat-treated leaves when incubated in an aqueous solution, suggesting a possible presence of enzymatic activities in the sun-dried leaves. They concluded that heat treatment may be a good method to

stabilize kaempferol 3-gentiobioside in *Cassia alata* leaves.

Hazni et al. (2008) isolated kaempferol, kaempferol 3-*O*-β-glucopyranoside, kaempferol 3-*O*-gentiobioside and aloe-emodin from the leaves. Cassiaindoline, a dimeric indole alkaloid (Villaseñor and Sanchez 2009) and kaempferol-3-*O*-β-D-glucoside (astragalin) (Saito et al. 2012) were isolated from *Cassia alata* leaves. Four anthraquinones (rhein (cassic acid), aloe-emodin, emodin and chrysophanol) were isolated from *Senna alata* leaves (Panichayupakaranant et al. 2009). Twelve compounds were isolated from *C. alata* leaves and identified as chrysoeriol (1), kaempferol (2), quercetin (3), 5,7,4'-trihydroflavanone (4), kaempferol-3-*O*-β-D-glucopyranoside (5), kaempferol-3-*O*-β-D-glucopyranosyl-(1→6)-β-D-glucopyranoside (6), 17-hydrotetratriacontane (7), *n*-dotriacontanol (8), *n*-triacontanol (9), palmitic acid ceryl ester (10), stearic acid (11) and palmitic acid (12) (Liu et al. 2009). Six compounds (kaempferol, kaempferol-*O*-diglucoside, kaempferol-*O*-glucoside, quercetin-*O*-glucoside, rhein and danthron) were isolated from the aqueous leaf extract (Saito et al. 2010). Leaves were also found to contain saponins (1.22 %), flavonoids (1.06 %), cardiac glycosides (0.20 %), cardenolides and dienolides (0.18 %), phenolics (0.44 %) and alkaloids (0.52 %) (Yakubu and Musa 2012).

The essential oil obtained by hydrodistillation of leaves of *C. alata* collected in Gabon afforded 44 compounds representing 92.5 % of the oil; the major constituents were linalool (23.0 %), borneol (8.6 %) and pentadecanal (9.3 %) (Agnaniet et al. 2005). The antioxidant activity of the oil was found to be low compared to that of butylated hydroxytoluene (BHT). Fifteen out of twenty-five constituents of *C. alata* leaf essential oil were identified in trace amount (i.e. <0.1 %) (Ogunwande et al. 2010). The oil was dominated by mono- and sesquiterpene compounds (48.7 and 47.9 %, respectively). The essential oil constituents were 1,8-cineole 39.8 %, β-caryophyllene 19.1 %, caryophyllene oxide 12.7 %, germacrene D 5.5 %, α-selinene 5.4 %, bicyclogermacrene 5.4 %, limonene 5.2 %, α-cadinol 4.2 %, α-phellandrene 3.7 %,

(*E*)-2-hexenal 3.3 %, α -bulnesene 1.0 %, tricyclene trace, (*E*)- β -ionone trace, benzaldehyde trace, α -terpinene trace, *n*-pentadecane trace, *p*-cymene trace, δ -cadinene trace, β -elemene trace, *n*-hexadecane trace, humulene epoxide II trace, (*E*)-geranyl acetone trace, tetradecanal trace, α -humulene trace and (*E*)- β -farnesene trace.

Phytochemicals in the Stem

Stems of *Cassia alata* were found to contain 1,5,7-trihydroxy-3-methylanthraquinone (alatinone) and dalbergin, 2,6-dimethoxybenzoquinone, santal, luteolin, β -sitosterol and β -sitosteryl- β -D-glucoside (Hemlata and Kalidhar 1993) and alantol (Hemlata and Kalidhar 1994).

Phytochemicals in the Flower, Pod and Seed

Two glycosides, chrysoeriol-7-*O*-(2''-*O*- β -D-mannopyranosyl)- β -D-allopyranoside and rhamnetin-3-*O*-(2''-*O*- β -D-mannopyranosyl)- β -D-allopyranoside, were isolated from the *Cassia alata* seeds (Gupta and Singh 1991). Two polyalcohols, glycerol and erythritol, were found in the seeds (Singh 1998). Hydroxyanthracene derivatives were found in the leaves, flowers and pods of *Cassia alata* (Panichayupakaranant and Intaraksa (2003). A water-soluble galactomannan with molecular weight 26,400 was isolated from the seeds (Gupta et al. 1987). The polysaccharide comprised of heptasaccharide units joined by β -(1 \rightarrow 4) linkages.

Phytochemicals in the Roots

Two new anthraquinone pigments 1,3,8-trihydroxy-2-methyl anthraquinone (A) and 1,5-dihydroxy-8-methoxy-2-methyl-anthraquinone-3-*O*- β -D-(+)-glucopyranoside (B) and β -sitosterol were isolated from the roots (Tiwari and Yadav 1971). Alquinone, an anthraquinone (Yadav and Kalidhar 1994); stigmasterol; and emodin (1,6,8-trihydroxy-3-methylanthraquinone) (Husain et al.

2005) were isolated from the roots. Chatsiriwej et al. (2006) found that root cultures established from the high-anthraquinone-producing plants accumulated higher amounts of emodin and chrysophanol than those established from the low-anthraquinone-producing plants and leaves and roots of the intact plants.

Six phenolic compounds, five anthraquinones (rhein, aloe-emodin, emodin, chrysophanol and physcion) and a flavonoid (kaempferol) were isolated from *C. alata* roots (Fernand et al. 2008).

Various plant parts of *Senna alata* have multifarious pharmacological activities that include laxative, antimicrobial, antiinflammatory, antimutagenic, analgesic, choleric, hypoglycaemic and hepatoprotective.

Antioxidant Activity

Methanol extracts of ten selected Nigerian medicinal plants including *C. alata* were found to contain steroids, terpenoids and cardiac glycosides, alkaloids, saponins, tannins and flavonoids (Akinmoladun et al. 2010). The highest amounts of total flavonoids were found in the leaf extracts of *C. alata* (275.16 μ g/mL quercetin equivalent). The extract demonstrated significant antioxidant and radical scavenging activities, namely, 2,2-diphenyl-1-picrylhydrazyl (DPPH) radical scavenging and hydroxyl radical scavenging activities, high lipid peroxidation inhibitory activity but low nitric oxide radical scavenging activity. The ethyl acetate extract of *S. alata* aerial parts was found to possess antioxidant properties as expressed by increase in antioxidant enzymes and the presence of phenolic compounds flavonoids naringin and apigenin (Okpuzor et al. 2009).

A refined *C. alata* leaf extract exhibited strong DPPH free radical scavenging activity with an IC₅₀ value of 2.27 μ g/mL and showed no prooxidant activity in yeast, *Saccharomyces cerevisiae* (Saito et al. 2012). Three of its major components were shown to bind to DNA in vitro. One major component, identified as kaempferol-3-*O*- β -D-glucoside (astragalin), showed high affinity to DNA. The astragalin-DNA binding

was found to occur through interaction with G–C base pairs, possibly by intercalation stabilized by H-bond formation.

Laxative Activity

Cassia alata and *Cassia podocarpa* have identical laxative potency and were the most likely candidates for laxative drug development in Nigeria (Elujoba et al. 1989). *Senna alata* leaves were found to have laxative effect and presumed to be due to active ingredient anthraquinones. In a multicentre randomized controlled clinical trial involving 80 adult patients with constipation, 28 patients were given at bedtime 120 mL of fluid with caramel colour, 28 administered mist. alba and 24 given *Cassia alata* infusion (Thamlikitkul et al. 1990). Eighteen per cent of patients in the placebo group passed stools within 24 hours, whereas 86 and 83 % of patients in mist. alba and *Cassia alata* groups, respectively, passed stools. The differences observed between placebo and mist. alba and placebo and *Cassia alata* were statistically highly significant. Minimal self-limited side effects, that is, nausea, dyspepsia, abdominal pain and diarrhoea, were noted in 16–25 % of the patients. Studies found *Cassia alata* fresh leaves showed significant purgative efficacy on volume and frequency in healthy subjects compared to placebo (Than et al. 2002).

In Thailand, *Senna alata* has been approved as a laxative drug in the Thai Herbal Pharmacopoeia 1998 and the Thai National List of Essential Drug 1999 (Panichayupakaranant and Intaraksa 2003). Hydroxyanthracene derivatives were demonstrated as the active constituents in this plant for the laxative property. The efficiency of herbal medicines depended on the plant raw material quality, which was usually related to the content of the active compounds. Recently, poor quality of *S. alata* leaves due to lower content of hydroxyanthracene derivatives relative to the standard value (i.e. not less than 1.0 % w/w of hydroxyanthracene derivatives, calculated as rhein-8-glucoside on a dried basis) had been a major problem in the production of the herbal medicines from *S. alata*. Studies found that the

method and temperature of drying markedly affected the hydroxyanthracene derivative content. Drying of the leaves in a hot air oven at 50 °C gave a higher hydroxyanthracene derivative content (1.43 % w/w) than drying in a hot air oven at 80 °C (0.44 % w/w) or drying in the sun (0.95 % w/w). Study on the stability of hydroxyanthracene derivatives in *C. alata* leaf powder, which was kept in tight container at room temperature, found that the hydroxyanthracene derivative content did not decrease within 9 months.

Antimicrobial Activity

In-Vitro Studies Leaf Extracts

Aqueous leaf extract of *C. alata* exhibited significant antifungal activity in-vitro against dermatophytes (Pankajalakshmi et al. 1993). *C. alata* leaf extract exerted no significant in-vitro activity against *Candida albicans*, *Penicillium* sp., *Aspergillus fumigatus*, *A. flavus*, *Mucor* sp. or *Rhizopus* sp., but at a dose of 2.5 % w/v, it completely inhibited the growth of *Trichophyton mentagrophytes*, *Trichophyton rubrum* and *Microsporum gypseum* (Palanichamy and Nagarajan 1990b). A combination of ethanol extracts of leaves of *Senna alata* and *Ocimum sanctum* exhibited anti-*Cryptococcus* activity. The activity of combination of the extracts was heat stable and worked at acidic pH. A 10-year human study indicated that the leaf extract could be reliably used as an herbal medicine to treat *Pityriasis versicolor*, a yeast fungus that causes skin disease (Damodaran and Venkataraman 1994). The leaf extract had no side effects.

Fuzellier et al. (1982) also found that rhein, emodol and some anthrones in *S. alata* leaves possessed antifungal activity against some fungal dermatophytes and yeast. The minimum inhibitory concentration (MIC) and minimum bactericidal concentration (MBC) for the water extract of *S. alata* against *Escherichia coli* were 1.6 and 60 mg/mL, respectively; corresponding data for chloramphenicol were 2 and 10 µg/mL (Crockett et al. 1992). Similarly, the MIC and minimum fungicidal concentration (MFC) for the extract against *Candida albicans* were 0.39 and 60 mg/mL in

contrast to 0.58 and 0.98 µg/mL for amphotericin B. From the dose–response curve plots, the extract had an IC₅₀ of 31 mg/mL for *E. coli* and 28 mg/mL for *C. albicans*. The scientists suggested that *S. alata* extracts contained agent(s) with therapeutic potential and might be useful if isolated and developed for the treatment of opportunistic infections of AIDS patients. Ethanol leaf extract exhibited high in vitro activity against various species of dermatophytic fungi but low activity against non-dermatophytic fungi (Ibrahim and Osman 1995). However, bacterial and yeast species showed resistance. The minimum inhibitory concentration (MIC) values of the extract revealed that *Trichophyton mentagrophytes* var. *interdigitale*, *Trichophyton mentagrophytes* var. *mentagrophytes*, *Trichophyton rubrum* and *Microsporum gypseum* had an MIC of 125 mg/mL, whereas *Microsporum canis* had MIC of 62.5 mg/mL. The inhibition observed on the macroconidia of *Microsporum gypseum* was structural degeneration related to cell leakage as observed by irregular, wrinkle shape and loss in rigidity of the macroconidia. Both aqueous and ethanol bark extracts of *Cassia alata* inhibited growth of *Candida albicans* in vitro (Reezal et al. 2002). The inhibitory activity was comparable to miconazole.

Aloe-emodin from *C. alata* leaves was found to be active against *Bacillus subtilis*, *Pseudomonas aeruginosa*, *Candida albicans*, *Trichophyton mentagrophytes* and *Aspergillus niger* with inhibitory activity indices of 1.8, 0.5, 0.5, 0.5 and 0.2, respectively (Hofilena et al. 2000). *Candida albicans* showed concentration-dependent susceptibility towards both the ethanol and water extracts from the barks but was resistant towards the extracts of leaves (Somchit et al. 2003). The growth of *Aspergillus fumigatus* and *Microsporum canis* was not affected by all types of the plant extracts. The antibacterial activity of *S. alata* extracts on *Staphylococcus aureus* was detected with only the leaf extracts using water and ethanol. The water extract exhibited higher antibacterial activity than the ethanol leaf extract.

The chloroform leaf extract was the most active against *Trichophyton mentagrophytes*, at a concentration of 50 mg/mL but it had no activity

against *Candida albicans* (Villaseñor et al. 2002). The hexane and ethyl acetate extracts showed some activity against both organisms, with the ethyl acetate extract being more active against *C. albicans*. Crude leaf extract of *Senna alata* showed significant inhibitory effect on *Streptococcus mutans*, a prominent bacterium that causes teeth decay (Limsong et al. 2004). In-vitro study showed that ethanol extract of *Senna alata* at 0.5 % inhibited adherence of *S. mutans* on glass surface significantly. The extract inhibited adherence of *S. mutans* ATCC 25175 and TPF-1 onto hydroxyapatite coated with saliva with IC₅₀ 0.5 and 0.4 %, respectively, as well as reduction of activities of glucosyltransferase and glucan-binding lectin by *Streptococcus mutans* strains. The findings showed that *Senna alata* could be a promising herb for toothpaste formulation with anti-teeth decay property. Among the methanol leaf extract of *Cassia alata*, *Cassia fistula* and *Cassia tora*, *C. alata* was the most effective leaf extract against *Trichophyton rubrum* and *Microsporum gypseum* with the 50 % inhibition concentration (IC₅₀) of hyphal growth at 0.5 and 0.8 mg/mL, respectively, whereas the extract of *C. fistula* was the most potent against *Penicillium marneffei* with the IC₅₀ of 0.9 mg/mL (Phongpaichit et al. 2004). Furthermore, all three *Cassia* leaf extracts also affected *M. gypseum* conidial germination where treated hyphae and macroconidia were shrunken and collapsed, which might be due to cell fluid leakage.

Of three crude leaf extracts, the methanol extract showed the highest activity followed by the ethanol extract and petroleum ether extract (Owoyale et al. 2005). The leaf extract exhibited higher activity against *Mucor* sp., *Rhizopus* sp. and *Aspergillus niger* with MIC of 70 µg/mL and lower activity against *Escherichia coli*, *Bacillus subtilis*, *Salmonella typhi*, *Pseudomonas aeruginosa*, *Staphylococcus aureus* and *Candida albicans* with MIC of at 860 µg/mL. Both aqueous and methanol leaf extracts of *C. alata* exhibited more antifungal than antibacterial activity (Makinde et al. 2007). The in vitro growth of the following fungi was inhibited (*Microsporum canis*, *Blastomyces dermatitidis*, *Trichophyton mentagrophytes*, *Candida albicans*

and *Aspergillus flavus*), while only two bacteria species were inhibited (*Dermatophilus congolensis* and *Actinomyces bovis*). Both aqueous and ethanol *S. alata* leaf inhibited the growth of *Candida albicans*, *Microsporium canis* and *Trichophyton mentagrophytes* better than the ketoconazole 200 mg used as a positive control (Timothy et al. 2012b). The minimum inhibitory concentration (MIC) of the water leaf extract for *Candida albicans*, *Aspergillus niger*, *Penicillium notatum*, *Microsporium canis* and *Trichophyton mentagrophytes* were 26.90, 32.40, 29.50, 30.30 and 27.80 mg, respectively, while the MIC of ethanol leaf extract for *Candida albicans*, *Aspergillus niger*, *Penicillium notatum*, *Microsporium canis* and *Trichophyton mentagrophytes* were 5.60, 3.50, 4.90, 12.60 and 9.80 mg, respectively. In another study, Timothy et al. (2012a) found that the aqueous leaf extract showed higher activity on *Escherichia coli* than ethanol leaf extract at 160 mg, whereas ethanol leaf extract had higher activity than aqueous leaf extract on *Salmonella typhi* at the same dose. The MIC for aqueous leaf extract ranged between 3.50 and 25.15 mg, while that of ethanol leaf extract was from 1.41 to 3.55 mg on the organisms tested. The presence of saponins, anthraquinones, cardiac glycosides, flavonoids, reducing sugars and terpenes were detected in both extracts.

The butanol and chloroform leaf extracts of *S. alata* both exhibited inhibition against methicillin-resistant *Staphylococcus aureus* (MRSA) with inhibition indexes of 1.03 and 0.78 at the concentration of 50 mg/mL (Hazni et al. 2008). The butanol leaf extracts afforded kaempferol (1), kaempferol 3-*O*- β -glucopyranoside (2), kaempferol 3-*O*-gentiobioside (3) and aloe-emodin (4) on purification. The four constituents showed varying degrees of inhibition against MRSA. Both 1 and 4 exhibited MIC₅₀ values of 13.0 and 12.0 μ g/mL, respectively. The kaempferol glycosides 2 and 3 were less active with MIC₅₀ values of 83.0 and 560.0 μ g/mL, respectively.

The acetone and ethanol (95 %) extract of *Senna alata* showed high antimicrobial activity against nearly all test microorganisms: *Staphylococcus aureus*, *Staphylococcus aureus* coagulase

positive, *Bacillus subtilis*, *Bacillus cereus*, *Bacillus stearothermophilus*, *Escherichia coli*, *Vibrio cholerae*, *Salmonella typhi*, *Shigella dysenteriae* and *Klebsiella pneumoniae* (Sakharkar and Patil 1998). The inhibitory effects of extracts were very close and identical in magnitude and were comparable with that of standard antibiotics used.

Cassia alata aqueous leaf extract exhibited antimicrobial activity against *Pseudomonas aeruginosa*, *Staphylococcus epidermidis*, *Staphylococcus aureus* and *Bacillus subtilis* (Saito et al. 2010). The extract also inhibited biofilm formation of *S. epidermidis* and *P. aeruginosa*. Six compounds from four bioactive fractions were identified as kaempferol, kaempferol-*O*-diglucoside, kaempferol-*O*-glucoside, quercetin-*O*-glucoside, rhein and danthron. In the *Salmonella*/microsome assay, the leaf extract showed weak mutagenicity (MI <3) only in strain TA98. *Cassia alata* leaf extract was found to have antibacterial activity in vitro against *Staphylococcus aureus* and *Bacillus subtilis* (Alalor et al. 2012).

Both flavonoid compounds 3,5,7,4'-tetrahydroxy flavone and 2,5,7,4'-tetrahydroxy isoflavone (100 μ g/disc) from *C. alata* leaves exhibited antifungal activity against most of the fungi, namely, human pathogens (*Trichophyton schoenleinii*, *Trichophyton longifurus*, *Pseudallescheria boydii*, *Candida albicans*, *Aspergillus niger*), animal pathogens (*Microsporium canis*, *Trichophyton mentagrophytes*) and plant pathogens (*Fusarium oxysporum* var. *lycopersici*, *Fusarium solani* var. *lycopersici*, *Macrophomina phaseolina*, *Rhizoctonia solani*) except for the human pathogen *Epidermophyton floccosum* (Rahaman et al. 2008). Compound 2,5,7,4'-tetrahydroxyisoflavone was highly active against *Trichophyton longifurus* and *Pseudallescheria boydii*, while compound 3,5,7,4'-tetrahydroxy flavones were moderately active against *Trichophyton longifurus* and *Pseudallescheria boydii*. Both compounds were moderately active against *Microsporium canis* and *Trichophyton mentagrophytes*. Both compounds were active against the plant pathogen *Fusarium solani* var. *lycopersici* but showed no activity against the other three plant pathogens.

S. alata leaf extract containing 16.7 % w/w anthraquinone exhibited antifungal activity against

Trichophyton rubrum, *T. mentagrophytes* and *Microsporum gypseum* with MIC values of 15.6, 62.5 and 250 µg/mL, respectively (Sakunpak et al. 2009). Five extracts of *Senna alata* leaf powder, namely, anthraquinone aglycone extract, anthraquinone glycoside extract, anthraquinone aglycones from glycosidic fraction, crude ethanol extract and anthraquinone aglycone from crude ethanol extract, were tested against clinical strain of dermatophytes: *Trichophyton rubrum*, *T. mentagrophytes*, *Epidermophyton floccosum* and *Microsporum gypseum* (Wuthiudomlert et al. 2010). The anthraquinone aglycones from glycosidic fraction qualitatively and quantitatively gave the best antifungal activity compared to the other extracts.

In-Vitro Studies Other Plant Part Extracts

The methanol extracts of *C. alata* leaves, flowers, stem and root barks exhibited a broad spectrum of antibacterial activity (Khan et al. 2001). The activity was increased on fractionation (petrol, dichloromethane, ethyl acetate), the dichloromethane fraction of the flower extract being the most effective. No activity was shown against tested fungi.

The crude *S. alata* flower extracts, containing steroids, anthraquinone glycosides, volatile oils and tannins, exhibited a high MIC of 500 µg/mL against *Staphylococcus aureus*, *Streptococcus faecalis*, *Micrococcus luteus*, *Bacillus subtilis* and *Pseudomonas putida* but was generally inactive against *Escherichia coli*, *Proteus vulgaris*, *Pseudomonas aeruginosa*, *Serratia marcescens* and *Pseudomonas fluorescens* (MIC >1,000 µg/mL) (Adedayo et al. 2001). However, the partially purified flower extract was bacteriostatic at a low concentration of 100 µg/mL, with a minimum bactericidal concentration of 500 µg/mL, primarily against the Gram-positive organisms. At a concentration slightly above the MIC, the purified extract was nearly as potent as standard antibiotics, even against multiple antibiotic-resistant local isolates that were resistant to methicillin, penicillin and streptomycin. The partially purified extract of *Senna alata* flower exhibited appreciable antibacterial activity against

Staphylococcus aureus, *Bacillus subtilis*, *Micrococcus luteus* and *Pseudomonas putida* (Adedayo et al. 2002). The mechanism of antibacterial activity of the *Senna alata* plant extract involved potassium ion and protein leakage. While maximum potassium leakage occurred within 30 minutes, protein efflux was at a peak after 75 minutes. Microscopic examination suggested that *Bacillus subtilis* cells were mummified while *Staphylococcus aureus* cells were lysed.

Extracts of water, methanol, chloroform and petroleum ether of *Senna alata* flowers also exhibited antimicrobial properties (Idu et al. 2007). Extracts tested at a final concentration of 500 µg/mL produced in vitro antimicrobial activities in assays against clinical isolates of *Staphylococcus aureus*, *Candida albicans*, *Escherichia coli*, *Proteus vulgaris*, *Pseudomonas aeruginosa* and *Bacillus subtilis*. Preliminary phytochemical analysis of the plant extracts showed the presence of phenols, tannins, anthraquinones, saponins and flavonoids. In another study, aqueous flower extract of *Senna alata* elicited 100 growth inhibition of aflatoxin-producing fungi *Aspergillus flavus* and *A. parasiticus* at 10 and 15 mg/mL concentrations (Abubacker et al. 2008). For the pathogenic fungi *Candida albicans* and *Microsporum audouinii* and plant pathogenic fungi *Fusarium oxysporum* and *Helminthosporium oryzae*, total inhibition occurred at 15 mg/mL concentration. The MIC values of the extract varied from 5.75 to 8.00 mg/mL for these fungi. *Senna alata* crude stem exhibited marked in vitro antifungal effects against *Microsporum canis*, *Trichophyton verrucosum* and *Trichophyton mentagrophytes* at concentrations of 10.00 and 5.00 mg/mL and *Epidermophyton floccosum* at concentration of 10.00 mg/mL (Sule et al. 2011). Phytochemical analysis revealed the presence of important secondary metabolites (tannins, steroids, alkaloids, anthraquinones, terpenes, carbohydrates and saponins) in the plant.

An herbal soap formulated with ethanol extract of *Cassia alata* exhibited excellent antimicrobial effect against Gram-positive bacteria and opportunistic yeast in the in vitro studies as well as in the palm-washing studies on volunteers

(Esimone et al. 2008). At a reduction time of 5 minutes, the herbal soap recorded a significantly lower mean viable microbial count of 2.12×10^4 cfu/mL (a reduction in microbial load of 94.78 %) as against the 4.07×10^5 cfu/mL recorded before the application of the soap. The herbal soap formulated with *Cassia alata* may have potential as an excipient in the production of antiseptic soaps.

Clinical Studies

Oladele et al. (2010) conducted a clinical trial involving 33 prison inmates; 19 were treated with *S. alata* soap and 14 untreated control (placebo). The *S. alata* soap consisted of *S. alata* leaf powder incorporated with caustic soda and palm kernel oil to make 1.5 % w/w. *Tinea versicolor* and *Tinea corporis* were the major fungal infections found on the skin lesions prior to study commencement, while *Epidermophyton floccosum* and *Cryptococcus* sp. were microscopically observed to be responsible for the lesions. After 4 weeks, *S. alata* soap significantly cleared the lesions on 16 subjects (94.1 %), comprising (11) *T. versicolor* and (5) *T. corporis*. None of the controls was cleared significantly. The study clearly confirmed the folkloric claims on *S. alata* as an antimicrobial agent for treating skin infections.

Hypoglycaemic Activity

Senna alata leaf extract administered orally had no effect on glucose levels in normoglycaemic animals, but it reduced the blood sugar value in streptozotocin-induced hyperglycaemic animals (Palanichamy et al. 1988). The ethyl acetate leaf extract was found to be hypoglycaemic (Villaseñor et al. 2002). At a dosage of 5 mg/20 g mouse, it decreased the blood sugar level of mice by 58.3 %.

Antiplatelet Activity

Adenine was isolated as a platelet-aggregating inhibitor from the leaves of *Senna alata* (Moriyama et al. 2003a). The inhibitory effect of

adenine was observed in the platelet aggregation induced by collagen (1.0 µg/mL as the final concentration), but little inhibitory effect was noted in the aggregation induced by ADP (adenosine 5'-diphosphate), whereas adenosine exhibited potent inhibitory effects on platelet aggregation induced both by collagen and ADP under the same experimental conditions.

Antiinflammatory Activity

Both the hexane and ethyl acetate leaf extracts exhibited antiinflammatory activity at a dosage of 5 mg/20 g mouse with a 65.5 and 68.2 % decrease in carrageenan-induced inflammation, respectively (Villaseñor et al. 2002). Antiinflammatory activities of heat-treated *Senna alata* leaf extract and kaempferol 3-*O*-gentiobioside (K3G) isolated from *C. alata*, a flavonoid glycoside, were demonstrated (Moriyama et al. 2003b). Strong inhibitory effects on concanavalin A-induced histamine release from rat peritoneal exudate cells both in the extracts of heat-treated and sun-dried *S. alata* leaves were observed. The heat-treated leaf extract was observed to exhibit stronger inhibitory effects than the effects of the sun-dried leaf extract at low concentrations in the studies of concanavalin A-induced histamine release, 5-lipoxygenase inhibition and also inhibition of cyclooxygenases (COX-1 and COX-2). In contrast, K3G showed weak inhibitory effects on concanavalin A-induced histamine release, 5-lipoxygenase and COX-1. No anti-hyaluronidase effect was detected in any of the materials tested.

Cassia alata hexane leaf extract significantly reduced knee circumference swelling in complete Freund's adjuvant (CFA) arthritic rats (Lewis and Levy 2011). Total and differential leukocyte counts in both blood and synovial fluid from *Cassia alata*-treated animals were significantly lower than in control animals. Protective effects against cartilage degradation on the femoral head of the knee joint were observed in *Cassia alata*-treated animals, as normal cartilage structure and chondrocyte arrangement were maintained. The results indicated that *Cassia alata* exerted

antiinflammatory activities that could potentially be exploited for antiarthritic therapies.

Hepatoprotective Activity

Crude extracts of flower petals in 0.5 % ethanol administered into the rats by intubation for 14 days prior to injection of 0.5 mL carbon tetrachloride (CCl₄)/kg elicited hepatoprotective activity (Wegwu et al. 2005). Serum aspartate aminotransferase and alanine aminotransferase levels decreased significantly in rats treated with the flower extract than in CCl₄-treated rats. In another study, pretreatment of *Cassia alata* leaf extract reduced the biochemical markers of hepatic injury-like elevated levels of serum glutamate pyruvate transaminase (SGPT), serum oxaloacetate transaminase (SGOT), alkaline phosphatase (ALP), total bilirubin and gamma glutamate transpeptidase (GGTP) induced by paracetamol in albino rats (Jayakar et al. 2009). Histopathological observations also revealed that pretreatment with the extract protected the animals from paracetamol-induced liver damage.

Anticancer Activity

Cassia alata was one of 29 Malaysian plants screened that exhibited in-vitro photocytotoxic activity by means of a cell viability test using a human leukaemia cell line HL60 (Ong et al. 2009). These 29 plants were able to reduce in vitro cell viability by more than 50 % when exposed to 9.6 J/cm² of a broad spectrum light when tested at a concentration of 20 µg/mL.

Cassia alata leaf extract was cytotoxic in parental A549 lung cancer cells and caspase-9 negative but not caspase-3 and -8 negative A549 cells (Levy and Lewis 2011). The IC₅₀ values were 143 and 145 µg/mL in parental and caspase-9 negative A549 cells, respectively. The flavonoid kaempferol was identified as a constituent of *Cassia alata* leaf extract and may be responsible for the effect. Rhein (4,5-dihydroxyanthraquinone-2-carboxylic acid), the primary anthraquinone in

the roots of *Cassia alata*, inhibited vascular endothelial growth factor (VEGF(165))-stimulated human umbilical vein endothelial cell (HUVEC) tube formation, proliferation and migration under normoxic and hypoxic conditions (Fernand et al. 2011). Further, rhein suppressed in vitro angiogenesis by inhibiting the activation of phosphatidylinositol 3-kinase (PI3K), phosphorylated-AKT (p-AKT) and phosphorylated extracellular signal-regulated kinase (p-ERK) but showed no inhibitory effects on total AKT or ERK. Rhein dose-dependently inhibited the viability of MCF-7 and MDA-MB-435s breast cancer cells under normoxic or hypoxic conditions and inhibited cell cycle in both cell lines. Additionally, rhein inhibited heat shock protein 90α (Hsp90α) activity to induce degradation of Hsp90 client proteins including nuclear factor-kappa B (NF-κB), COX-2 and HER-2. Rhein also inhibited the expression of hypoxia-inducible factor-1α (HIF-1α), vascular endothelial growth factor (VEGF(165)), epidermal growth factor (EGF) and the phosphorylation of inhibitor of NF-κB (I-κB) under normoxic or hypoxic conditions. The findings indicated rhein to be a promising antiangiogenic compound for breast cancer cell viability and growth.

Antimutagenic Activity

Aloe-emodin from *C. alata* leaves was found to have antimutagenic activity (Hofilena et al. 2000). Micronucleus test indicated a 71 % reduction in the number of micronucleated polychromatic erythrocytes induced by mitomycin C. The chloroform leaf extract was antimutagenic, at a dosage of 2 mg/20 g mouse, with a 65.8 % inhibition in the mutagenicity of tetracycline (Villaseñor et al. 2002).

Anthelmintic Activity

C. alata leaves are used as anthelmintic for dogs in Trinidad and Tobago (Lans et al. 2000). *C. alata* leaf extracts inhibited egg hatchability and killed infective larvae of *Haemonchus*

contortus in a concentration-dependent manner (Ademola and Eloff 2011). The best-fit values were 0.562, 0.243, 0.490, 0.314 and 0.119 mg/mL for the acetone extract, chloroform, hexane, butanol and 35 % water in methanol fractions, respectively, when tested against nematode eggs. The best-fit LC₅₀ values were 0.191, 0.505, 1.444, 0.306 and 0.040 mg/mL for acetone extract, chloroform, hexane, butanol and 35 % water in methanol fractions, respectively, when tested against larvae. The 35 % water in methanol fraction was the most active against the larvae and eggs of *H. contortus* demonstrating the lowest LC₅₀ values.

Cestode parasites *Hymenolepis diminuta* treated with *C. alata* leaf extract showed a decrease in motility with an increase in concentrations and complete immobilization took lesser time compared to control (Kundu et al. 2012). Ultrastructural micrographs of paralyzed worms revealed swelling of the tegument and blebbing on the tegumental surface throughout the body accompanied with destruction of microtriches and changes such as shrinkage in the scolex region. Depletion of parenchyma cells and destruction in the connective tissues along with sparsely cytoplasmic cytons were also observed, and these observations were similar with worms treated with a known drug praziquantel.

Antiallergic Activity

The hydroalcoholic extract of *Cassia alata* leaves significantly inhibited mast cell degranulation at 200 mg/kg dose in rats (Singh et al. 2012). Both its chemical constituents rhein and kaempferol also showed potent (>76 %) inhibition of mast cell degranulation at 5 mg/kg. The extract and rhein inhibited lipoyxygenase enzyme with IC₅₀ values of 90.2 and 3.9 µg/mL, respectively, whereas kaempferol was inactive. The results suggested that *Cassia alata* exhibited antiallergic activity through mast cell stabilization and lipoyxygenase have inhibition and may have potential as alternative treatment for allergic diseases.

Antimalarial Activity

Saye, a combination remedy prepared from N'Dribala, *Cochlospermum planchonii* root, *Cassia alata* leaf, *Phyllanthus amarus* whole plant and *Azadirachta indica* fruits, is a plant remedy commonly used by traditional healers for the treatment of malaria in Burkina Faso (Traoré et al. 2008; Yerbanga et al. 2012). 'Saye' showed a significant effect against *Plasmodium falciparum* and *Plasmodium berghei* parasites grown in vivo (IC₅₀=80.11 µg/mL; ED₅₀)=112.78 mg/kg). In vitro the activity was lower. Aqueous extracts of Saye, N'Dribala and *Azadirachta indica* preparations orally administered to mice elicited prophylactic activity and reduced *Plasmodium berghei* parasitaemia in treated mice, with respect to controls, by 52.0, 45.5 and 45.0 %, respectively (Yerbanga et al. 2012). No evidence of transmission blocking effects was detected with any of the tested remedies.

Choleretic Activity

Studies in rats showed that choleretic activity of *Senna alata* at 15 mg/kg was better than 15 mg/kg of hydroxycyclohexenyl-butyrate (Hebecol ND), a synthetic choleretic, but at elevated doses, the plant extract inhibited bile secretion (Assane et al. 1993).

Analgesic Activity

The extract of the leaves of *Senna alata* and kaempferol 3-*O*-sophoroside exhibited analgesic activity (Palanichamy and Nagarajan 1990a). Maximum analgesic activity of the extract was apparent 120 minutes after intraperitoneal injection using the tail clip, tail-flick, tail immersion and acetic acid-induced writhing methods. Fifty milligrams of kaempferol 3-*O*-sophoroside appeared equivalent to 100 mg of the extract. Cassiaindoline, a dimeric indole alkaloid isolated from *Cassia alata* leaves, exhibited analgesic activity at a dosage of 125.0 mg/kg mouse and decreased the number of writhings induced by acetic acid by 49.4 % (Villaseñor and Sanchez

2009). It also showed a 57.1 % antiinflammatory activity at a dosage of 75 mg/kg mouse.

Acaricidal Activity

The ethanol leaf extract of *C. alata* produced a concentration-dependant increase in the adult tick *Rhipicephalus (Boophilus) annulatus* mortality (Ravindran et al. 2012). The highest mortality (45.8 %) and inhibition of fecundity (10.9 %) were observed at the highest concentration tested (100 mg/mL). The leaf extract did not affect egg hatchability.

Hypolipidaemic/Anti-obesity Activity

Studies demonstrated that *Cassia fistula* and *S. alata* methanol leaf extracts could significantly lower body weight of diet-induced lipidaemic mice (Chichioco-Hernandez and Leonido 2011). Furthermore, parametrial fat weight of mice was also decreased in a dose-dependent manner, thus confirming the weight-lowering potential of both plants.

Immunological Activity

Among the eight pollen types sample extract tested, *Ricinus communis* was found to contain the highest amount of soluble protein, free amino acid and total carbohydrate, per gram of dry weight followed by *Imperata cylindrica* and *Cassia alata* (Sharma et al. 2009). Maximum numbers of protein polypeptide bands were detected in the sample extract of *Cassia alata* followed by *Acacia auriculiformis*, *Imperata cylindrica* and *Cocos nucifera*. IgE binding protein fractions were maximum in *Cassia alata* and minimum in *Trewia nudiflora*.

Abortifacient Activity

Senna alata leaf extract (250, 500, 100 mg/kg bw) administered to pregnant Wistar rats significantly

reduced the number of live foetus, weight and survival ratio of the foetus, numbers of implantations and corpora lutea, implantation index, progesterone, prolactin, estradiol, follicle stimulating and luteinizing hormones whereas the number of dead foetus, number and percentage of rats that aborted, percentage vaginal opening, resorption index and pre- and post-implantation losses increased significantly (Yakubu et al. 2010). The abortifacient effects were most pronounced at 500 and 1,000 mg/kg body weight of the extract and were similar to the animals treated with 2.85 mg/kg body weight of mifepristone, the reference drug. All cases of abortion were accompanied with vaginal bleeding. Although, the final weight of the rats increased significantly, the feed and water intake were not significantly altered in all the treatment groups. The weight of the uterus, uterine-body weight ratio, length of the right uterus horn and uterine cholesterol decreased significantly in all the treatment groups. The uterine alkaline phosphatase activity and glucose concentration increased in only the extract-treated animals, whereas mifepristone decreased the uterine alkaline phosphatase activity and glucose content of the animals. Hormonal influence, changes in implantation site, estrogenicity and uterogenicity were suggested as possible mechanism of abortifacient activity of aqueous extract of *S. alata* leaves. Phytochemical screening of the leaf extract showed positive results for saponins (1.22 %), flavonoids (1.06 %), cardiac glycosides (0.20 %), cardenolides and dienolides (0.18 %), phenolics (0.44 %) and alkaloids (0.52 %). Overall, the extract may be used as an abortifacient especially at 500 and 1,000 mg/kg body weight and therefore not safe for consumption as oral remedy during pregnancy. The results provided evidence to the age-long claim of *S. alata* leaves in 'washing the uterus'. In subsequent studies, they found that administration of the crude alkaloids from *Senna alata* leaves elicited decreases in the activities of alkaline phosphatase (ALP), gamma glutamyl transferase (GGT), aspartate (AST) and alanine transaminases in the liver and kidney of the animals by the alkaloids and were accompanied by corresponding increases in the serum enzymes (Yakubu and

Musa 2012). The alkaloids reduced liver- and kidney-body weight ratios, serum globulin, urea, uric acid and phosphate ions, while the serum concentrations of albumin, bilirubin, creatinine, potassium ions, AST/ALT ratio and blood urea nitrogen to creatinine ratio increased. They concluded that the alkaloid at doses of 250–1,000 mg/kg body weight produced permeability changes in the plasma membrane of the organs and adversely affected the normal secretory, synthetic and excretory functions of these organs.

Miscellaneous Pharmacological Activities

Pharmacological studies showed that the hexane, chloroform and ethyl acetate leaf extracts caused an immediate decrease in motor activity, enophthalmos, hyperaemia, micturition and diarrhoea (Villaseñor et al. 2002). At a dosage of 150 mg/20 g mouse, the ethyl acetate leaf extract caused paralysis, screen grip loss and enophthalmos accompanied by drooping and closure of the eyelids.

Toxicity Studies

The aqueous leaf extract of *Senna alata* induced an adverse effect on haematological indices in albino rats (Sodipo et al. 1998). Increasing doses (10, 50, 100 and 150 mg/kg bw) of the extract administered orally to different groups of rats daily for a period of 14 days produced significant dose-dependent decreases in the levels of haemoglobin (Hb) and erythrocyte count. However, mean corpuscular haemoglobin (MCH) did not show any change. Clinical symptoms of loss of appetite, emaciation and loss of weight in the treated rats indicated toxicity. The observed symptoms of toxicity were attributed to the saponin content of the plant extract. Contradictory results were found in another study. Acute and subacute toxicity study of aqueous ethanol leaf extracts of *S. alata* in Swiss mice and Wistar albino rats found no observable toxicity symptoms or animal death during or at the end of the

experimental period (Pieme et al. 2006). The results indicated that the medium lethal dose (LD_{50}) was about 18.50 g/kg of body weight. Rats treated with various doses of hydroethanolic leaf extract had a progressive weight gained, and this increase in weight was significantly different from that of the control. The effect of *S. alata* appeared to have a protective effect, after 26 days dosage of hydroalcoholic extract of *S. alata*; there were no significant changes in alanine aminotransferase (ALT), aspartate aminotransferase (AST) and alkaline phosphatase (APL) activities in the serum of both sexes and the 20 % homogenate liver samples. The extract had a protective effect on hepatocytes and appeared to improve liver architecture. The study presented strong evidence of the nontoxic effect of the hydroethanolic leaf extract of *S. alata*.

The TRAMIL research group in the Caribbean validated the recommendation of the use of the leaves to cure eczema and 'ringworm', by rubbing on the skin or using an infusion of 15–20 leaflets per litre of water to wash affected areas of the skin (Robineau 1995). TRAMIL researchers have shown that following peritoneal dosing in rats at 2 g/kg, the ethanol extract from the leaf showed no significant toxicity. In all cases extemporaneous preparation should not be kept for more than 1 day. They also found the bark to be rich in tannins and seeds to be a good source of gums for use in ointments and herbal soaps. They found that sennosides are contraindicated in cases of obstruction, acute intestinal inflammation, ulcerative colitis, appendicitis and abdominal pain of unknown origin and for children under the age of 12. With chronic use, hypokalaemia may occur. During the first trimester of pregnancy, senna pod preparations should be used only if a therapeutic effect cannot be obtained with a change in diet or through the use of bulk laxatives.

Traditional Medicinal Uses

The leaves, flowers, fruits, seeds and root bark are used for medicinal purposes in folkloric medicine. In the Indian system of medicines, namely,

Ayurveda, Siddha and Unani, decoctions of the leaves, flowers, bark and wood are used in skin diseases like eczema, pruritus, itching and constipation (Kirtikar and Basu 1975). In the Philippines, the leaves are employed for ringworm and other skin diseases, like itches (BPI 2005). According to Philippines Bureau of Plant Industry (BPI 2005), the leaves are official in the Pharmacopoeia of India. The Pharmacopoeia of India mentions an effective ointment made of the leaves. In India, the plant is regarded as a cure for poisonous bites and for venereal eruptions. The sap of the leaves is an efficient antiherpetic. The leaves are taken internally as an aperient. A decoction of the leaves and flowers is used as an expectorant in bronchitis, asthma and dyspnoea; as an astringent; and also as a mouthwash in stomatitis. A strong decoction of the leaves and flowers is a good wash for eczema. A strong decoction of the leaves is abortifacient. The seeds are used as a vermifuge. A decoction of the roots is used against tympanitis. The wood is used as an alternative. Decoctions of the wood are used to treat liver problems, urticaria, rhinitis and loss of appetite caused by gastrointestinal problems. In the Antilles, Reunion and Indo-China, it is reported that the plant is reputed as hydragogue, sudorific and diuretic. Decoctions of the leaves, flowers, bark and wood are used in skin diseases such as eczema, pruritus and itching and in constipation (Palanichamy and Nagarajan 1990b). The flowers are also used in bronchitis and asthma. The leaves are traditionally used for the treatment of skin diseases such as ringworm and pityriasis versicolor (Husain et al. 2005). An infusion of the roots is used to treat rheumatism and also used as a strong laxative (Reezal et al. 2002). The seeds and leaves are used as fungicide, vermifuge and for skin problems in Mangalore, India (Shiddamallayya et al. 2010).

For laxative purposes usually a decoction of the leaves is drunk, and less often the flowers, roots or the stem are used. Skin problems treated with *Senna alata* include ringworm, favus and other mycoses, impetigo, syphilis sores, psoriasis, herpes, chronic lichen planus, scabies, rash and itching (Bosch 2007). Other ailments treated in tropical Africa with *Senna alata* include stomach

pain during pregnancy, dysentery, haemorrhoids, blood in the urine (schistosomiasis, gonorrhoea), convulsions, heart failure, oedema, jaundice, headache, hernia and one-sided weakness or paralysis. A strong decoction made of dried leaves is used as an abortifacient. In veterinary medicine too, a range of skin problems in livestock is treated with leaf decoctions. Such decoctions are also used against external parasites such as mites and ticks. *Cassia alata* extract is used in traditional medicine practice for the treatment of some external skin infections in Nigeria, the juice expressed from the young leaves being applied topically to the skin (Benjamin and Lamikanra 1981; Alalor et al. 2012). *Senna alata* is widely used in ethnomedicine practice for the treatment of hypertension, sickle cell anaemia and diabetes in southwestern Nigeria (Okpuzor et al. 2009). Saye, a combination remedy prepared from *Cochlospermum planchonii*, *Cassia alata* and *Phyllanthus amarus*; N'Dribala, a *Cochlospermum planchonii* root decoction; and a fruit preparation of *Azadirachta indica* are plant remedies of the folk medicine in Burkina Faso and are commonly used by traditional healers for the treatment of malaria (Yerbanga et al. 2012). Leaves are commonly employed for constipation in Nigeria and other African countries. Leaves are used as tea for intestinal worm infestation and a leaf decoction drunk for gonorrhoea in Ghana (Irvine 1961) and in Senegal (Kerharo and Adam 1974), while a root decoction is drunk for gonorrhoea in Congo (Bouquet 1969). In Togo and Gabo, pounded leaves are used directly on the skin or mixed with palm oil for dermatitis (Adjanohoun et al. 1986; Akendengue and Louis 1994).

In Thailand, *S. alata* has been approved as a laxative drug in the Thai Herbal Pharmacopoeia 1998 and the Thai National List of Essential Drug 1999. In Thailand, aqueous extracts of the leaves of *Cassia alata* and *Lawsonia alba* are used in native medicine for ringworm infections (Pankajalakshmi et al. 1993). In Thailand, the leaves are used as laxative for treating constipation; fresh leaves are pounded with water, garlic and red lime and smear on ringworm-infected skin; shoots and leaves are boiled and used and

the preparation used for cleaning abscesses and wounds as antiinflammatory (Monkheang et al. 2011). In Vietnam, *C. alata* is employed to treat constipation, oedema, hepatalgia and jaundice (Le and Nguyen 1999). It is used externally for ringworm, tinea imbricata (tokelau) and herpes circinatus. In Peninsular Malaysia, the juice of the leaves is used or sometimes mixed with lime for ringworm infestations (Burkill 1966). Roots are also used externally for ringworm and also prescribed for constipation. The pods and seeds are eaten as vermifuge. A decoction of the cooked leaves or flowers was taken as purgative in Indonesia. In Sarawak, pounded fresh leaves are rubbed on ringworm infestations and for dhobi itch, and a drink is prepared from young leaves and roots for diarrhoea (Chai 2006).

Other Uses

The tree is planted as shade tree, for soil covering, as protection against driver ants and as medicinal plant. It is often grown as an ornamental, and in the Pacific Islands, it is sometimes planted to improve taro patches. The seeds are a source of gum.

The leaf extract can be used in veterinary medicine. The use of ointments made with ethanol leaf extracts of leaves of *Senna alata*, as topical treatments on chronic crusty or acute lesions of bovine dermatophilosis, induced healing of the disease in infected animals treated without recurrence for more than 3 years (Ali-Emmanuel et al. 2003).

Comments

S. alata has been introduced and naturalized in many countries, and in some countries, it has become a weed. For instance, *Senna alata* is regarded as a significant environmental weed in the Northern Territory and as an environmental weed in Queensland and Western Australia. It is also regarded as a potential environmental weed or 'sleeping weed' in northern New South Wales.

Senna auriculata

Scientific Name

Senna auriculata (L.) Roxb.

Synonyms

Cassia auriculata L., *Cassia densistipulata* Taub.

Family

Fabaceae also placed in Caesalpiniaceae

Common/English Names

Avaram Senna, Matara Tea, Styptic Weed, Tanner's Cassia, Tarwar

Vernacular Names

Burmese: Peikthingat

Chinese: Er Ye Jue Ming

French: Avaram

Sri Lanka: Ranawara (Sinhalese)

Origin/Distribution

Senna auriculata is a native of India, Myanmar and Sri Lanka and has been successfully introduced into several African countries. It has been suggested that it is indigenous in Tanzania, but an early introduction and naturalization seem more likely. It is cultivated in India and Sri Lanka and occasionally elsewhere.

Agroecology

Under natural or naturalized conditions, *Senna auriculata* is found in woodlands and wooded grasslands up to 600 m altitude. It usually grows wild in dry regions with a minimum annual precipitation of 400 mm, but it also tolerates wet climates with an annual precipitation of up to 4,300 mm. It grows well in areas with mean annual temperature range of 16–27 °C. *Senna auriculata* needs full sun. It tolerates many soil types, including saline soils but prefers fairly rich, well-drained, friable soils.

Edible Plant Parts and Uses

The flowers, young leaves and young tender pods are edible (Watt 1908; Burkill 1966; Facciola 1990; Rahmansyah 1991; Reddy et al. 2007). Flowers are eaten as vegetables in Andhra Pradesh, India (Reddy et al. 2007). The leaves are

made into a refreshing cooling drink in India. The leaves are sometimes used to make tea, dried flowers serve as a coffee substitute, and in times of food scarcity, the young tender pods, young leaves and flowers are eaten as a vegetable (Rahmansyah 1991). A fermented mixture of pounded bark and dissolved molasses serves as an alcoholic beverage in some parts of India.

Botany

A branched shrub or small tree 1.5–5 m high (Plate 1), with a trunk diameter up to 20 cm and with thin, brown, lenticellate bark. Leaves alternate, paripinnately compound with 6–13 pairs leaflets (Plates 1 and 2); stipules large and leafy, broadly reniform, 7–22 mm wide, persistent; petiole 10–14 cm long; rachis provided with a gland between each pair of leaflets. Leaflet oblong-elliptical to obovate-elliptical, 10–35 × 5–12 mm, rounded and mucronate at apex, glabrous to pubescent. Inflorescence an axillary raceme, 2–8 flowered (Plates 1 and 3). Flower (Plate 4) bisexual, zygomorphic, pentamerous, 4–5 cm across; sepals rounded at apex, imbricate, glabrous; petals free, imbricate, unequal, 1.5–3 cm long, yellow; stamens 10, the 3 lower ones largest and fertile, others usually sterile; ovary superior, falcate, with 1.5 cm long, stalked, style (fruit a flattened cylindrical pod 5–18 × 1–2 cm, transversely undulate between the 10–20 seeds, indehiscent, green turning to brown when mature.

Plate 2 Upper and lower surface of pinnate leaves (GF Chung)

Plate 5 Ripe and mature pods (GF Chung)

Plate 3 Inflorescence with yellow flowers (GF Chung)

Plate 4 Close up of flower (GF Chung)

Seeds compressed ovoid-cylindrical, $7-9 \times 4-5$ mm, with a distinct areole on each surface (Plate 5).

Nutritive/Medicinal Properties

Leaf Phytochemicals

Five compounds were isolated from the leaves (Varshney et al. 1973). Compounds A, B and C were found to be saturated higher aliphatic fatty alcohols and formed 2:4-dinitrophenylhydrazone derivatives, compound D gave all characteristics of a sterol, and compound E was identified as an anthraquinone pigment, emodin (1,6,8-trihydroxy-3-methylantraquinone). Di-(2-ethyl) hexyl phthalate was isolated from *Cassia auriculata* leaves (Nageswara Rao et al. 2000). Leaves were reported to contain carbohydrates, phenols, lipids, proteins, saponins, flavonoids, tannin, terpenoids and cardiac glycosides (Senthilkumar and Vijayakumari 2012). Thirteen bioactive compounds were identified in the ethanol leaf extract, and the major constituents were phytol, octadecane 1-(ethenyloxy)- and *E*-10-pentadecenol. Other components included resorcinol; 3-*O*-methyl-D-glucose; 1,14-tetradecanediol; 3,7,11,15-tetramethyl-2-hexadecen-1-ol; 2*H*-cyclopropa[*a*] naphthalen-2-one, 1,1a,4,5,6,7,7a,7b-octahydro-, 1,7,7-tetramethyl-(1aa,7a,7aa,7ba)-; azulene, 1,2,3,5,6,7,8,8a-octahydro-1,4-dimethyl-7-(1-

methylethenyl)-, [1*S*-(1*a*,7*a*,8*aa*)]-; 1,2-benzene dicarboxylic acid, diisooctyl ester; squalene; 1-cyclohexylnonene; and 1-4-[(2-diethylamino) ethylamino[6-methyl-2-pyrimidinyl]-3-[3,4,5-trimethoxyphenyl] guanidine.

Twenty-nine compounds were found in *C. auriculata* leaves (Anandan et al. 2011). The main constituents were 3-*O*-methyl-D-glucose (48.50 %), α -tocopherol- β -D-mannoside (14.22 %), resorcinol (11.80 %), *n*-hexadecanoic acid (3.21 %), 13-octadecenal, (*Z*)- (2.18 %), 1,2,3,4-tetrahydroisoquinolin-6-ol-1-carboxylic acid (1.98 %), unknown (3.29 %), unknown (2.61 %) and unknown (1.14 %). Other minor constituents were glycerine (0.16 %), thymine (0.11 %), 1-butanol, 3methyl-, formate (0.17 %), 4*H*-pyran-4-one,2,3-dihydro-3,5-dihydroxy-6-methyl (0.46 %), benzaldehyde,4 methyl- (0.83 %), 2-propenoic acid, 4-methylpentyl ester (0.125), sucrose (1.2 %), 1,6,anhydro- β -D-glucopyranose (levoglucosan) (0.3 %), β -D-glucopyranoside, methyl (0.36 %), 1,2-benzenedicarboxylic acid, bis(2-methylpropyl) ester (1 %), benzenamine,2,3,4,5,6-pentamethyl (0.87), unknown (0.57 %), hexadecanoic acid, ethyl ester (0.1 %), 1-tridecyne (0.3 %), 13-oxabicyclo[10.1.0] tridecane (0.42 %), phytol (0.61 %), 1-*E*,11,*Z*-13-octadecatriene (0.56 %), 1 octadecanoic acid (0.46 %), α -tocopherol (1.16 %) and *N*-acetyl tyramine (1.24 %).

Seed/Pod Phytochemicals

Sterols, anthracene derivatives, triterpenoid and tannins were isolated from the ethanol extract of the pods (Suresh et al. 2007).

The following chemicals were identified in the seed extract: *n*-hexadecanoic acid (21.31 %), grapeseed oil (linoleic and oleic acids) (31.02 %), *E*,*Z*-1,3,12-nonadecatriene (12.27 %), stearic acid (9.39 %), benzoic acid, 2-hydroxy-methyl ester (0.07 %), β -ethoxypropionaldehyde diethyl acetal (0.86 %), ethyl caprylate (0.14 %), 2-methoxy-4-vinylphenol (0.36 %), glycine, *N*-(trifluoroacetyl)-, 1-methylbutyl ester (0.10 %), 2,3-dihydro-3,5-dihydroxy-6-methyl-4*H*-pyran-4-one (0.12 %), capric acid ethyl ester (0.16 %), resorcinol (0.21 %) dodecanoic acid

(0.48 %), 3'5'-dimethoxyacetophenone (0.58 %), 9-octadecenoic acid, (*E*)-(12.60 %), palmitic acid β -monoglyceride (2.95 %), dl- α -tocopherol (1.22 %) and stigmasta-5,23-dien-3-ol,(3 β)-(1.21 %) (Raj et al. 2012).

Polyphenols quantified in the hydroalcoholic seed extract of *C. auriculata* were epicatechin (14 %), catechin (4.5 %) and procyanidin B1 (1 %), while the supercritical fluid extract contained catechin (6 %) and epicatechin gallate (20 %) (Puranik et al. 2011).

Flower Phytochemicals

The flower of *C. auriculata* was found to contain a flavonol glycoside 5-*O*-methylquercetin 7-*O*-glucoside (Manogaran and Sulochana 2004). The hydromethanolic extract and its ethyl acetate and *n*-butanol fractions of the flowers were found to contain phenolic compounds, carbohydrates, tannins, steroids and amino acids (Surana et al. 2009).

Root Phytochemicals

Phytochemical analysis of the crude root extracts revealed the presence of an array of active chemical constituents such as tannins, flavonoids, glycosides, carbohydrates, steroids and triterpenoids (Wadekar et al. 2011).

Plant Phytochemicals

C. auriculata was reported to contain leucopelargonidins, flavan-3,4-diols of the 'phloroglucinol series' (Paris and Cubukcu 1962). From the aerial plant parts, the following compounds were isolated: kaempferol-3-*O*-rutinoside, rutin, kaempferol, quercetin and luteolin (Juan-Badaturuge et al. 2011; Habtemariam 2013), and oleanolic acid (Senthilkumar and Reetha 2011).

Some of the reported pharmacological properties of the various plant parts of *Cassia auriculata* are elaborated below.

Antioxidant Activity

The ethanol and methanol extracts of *C. auriculata* flowers showed antioxidant activity in both 2,2'-azinobis-(3-ethylbenzothiazoline-6-sulfonic acid) (ABTS) and 1,1-diphenyl-2-picrylhydrazyl (DPPH) radical scavenging assays (Kumaran and Karunakaran 2007). The flower powder of *Cassia auriculata* significantly decreased the thiobarbituric acid reactive substances (TBARS), hydroperoxide and conjugated dienes and increased the antioxidant enzymes (catalase, superoxide dismutase and glutathione peroxidase) and non-enzymatic antioxidants (ascorbic acid, vitamin E and reduced glutathione) in streptozotocin-induced diabetic rats (Jeyashanthi and Ashok 2010). The antioxidative effect of 200 mg/kg body weight (bw) of the extract was significantly better than 100 mg/kg body weight extract and the reference drugs (tolbutamide and metformin). Antioxidative effect was not observed in normoglycemic rats in the experiment. In another study, oral administration of *C. auriculata* aqueous leaf extract to streptozotocin-induced mild diabetic (MD) and severe diabetic (SD) rats (100, 200 and 400 mg/kg bw per day for a period of 21 days) produced significant fall in fasting blood glucose (FBG) in a dose-dependent manner (Gupta et al. 2009c). Treatment with the extract (400 mg/kg) showed significant reduction in serum levels of thiobarbituric acid reactive substances (TBARS) and oxidized low-density lipoprotein (OxLDL) in both MD and SD rats. The antioxidant defence system was also found to be improved in extract-treated (400 mg/kg) MD and SD rats, as revealed by significant increase in activities of erythrocyte's antioxidant enzymes, that is, superoxide dismutase (SOD) and catalase (CAT) with a concomitant elevation in erythrocyte's reduced glutathione (GSH) content. Moreover, there were no toxic signs in rats treated with high doses of the extract (1,000 and 2,000 mg/kg bw per day for 21 days). Blood glucose, hepatic and renal function parameters in these rats were found within normal limits.

The alcoholic extract of the aerial part of *C. auriculata* exhibited potent antioxidant activity when assessed by DPPH radical scavenging,

lipid peroxidation and reducing power analysis (Juan-Badaturuge et al. 2011). Fractionation of the crude extract showed that the ethyl acetate fraction was the most active followed by the chloroform fraction, while the petroleum ether, *n*-butanol and water fractions were less active than the crude extract.

Anticancer Activity

Cassia auriculata leaf ethanol extract dose-dependently inhibited the growth of human breast adenocarcinoma MCF-7 and human larynx carcinoma Hep-2 cell lines in vitro with IC₅₀ values of 400 and 500 µg through induction of apoptosis (Prasanna et al. 2009). The MCF-7 and Hep-2 cells showed decreased expression of antiapoptotic Bcl-2 protein and increased expression of Bax/Bcl-2 ratio upon treatment. When *Cassia auriculata* extract and curcumin were combined, a synergistic effect of anticancer activity at a much lower concentration of both was noted (Prasanna et al. 2011).

Antimicrobial Activity

Cassia auriculata leaf extract exhibited significant broad spectrum activity in-vitro against *Bacillus subtilis* and *S. aureus* (Samy and Ignacimuthu 2000). Studies conducted in birds with *Escherichia coli* infection showed that *C. auriculata* herbal extract had more potent microbicidal activity compared to *Piper betle* (Prakash 2006). The methanol leaf extract (5 mg/disc) and methanol flower extract (2.5 mg/disc) showed in-vitro growth inhibitory activity against *Bacillus subtilis*, *Staphylococcus aureus*, *Staphylococcus epidermidis* and *Enterococcus faecalis* (Duraipandiyani et al. 2006). The methanol flower extract (5 mg/disc) showed antibacterial activity against all four bacteria and *Escherichia coli*.

The ethanol, methanol and aqueous extracts of dry flowers and ethanol, methanol and acetone extracts of fresh flowers of *Cassia auriculata* exhibited in-vitro antibacterial activity against *Staphylococcus aureus*, *Enterococcus faecalis*,

Bacillus subtilis, *Salmonella typhi*, *Salmonella paratyphi* A, *Escherichia coli*, *Proteus mirabilis*, *Pseudomonas aeruginosa*, *Klebsiella pneumoniae*, *Vibrio cholerae* and *Shigella dysenteriae* (Maneemegalai and Naveen 2010). The maximum activity was observed against all organisms except *Pseudomonas aeruginosa* and *Klebsiella pneumoniae*. The minimum inhibitory concentration ranged between 12.5 and 75 mg/mL depending on microorganism and various extract. Presence of phytochemicals such as terpenoids, tannins, flavonoids, saponin, cardiac glycosides and steroids was observed. Of several plant species, *Cassia auriculata* was selected as the efficient plant, which showed antibacterial activity against *Escherichia coli*, *Salmonella typhi*, *Proteus mirabilis* and *Klebsiella pneumoniae* at different concentrations Senthilkumar and Reetha 2011).

Antiinflammatory Activity

The 50 % acetone flower extract of *C. auriculata* showed marked antiinflammatory activity (56 %) in carrageenan-induced oedema in rats (Manogaran and Sulochana 2004).

Antidiabetic Activity

Administration of aqueous *Cassia auriculata* flower extract at 0.45 g/kg significantly decreased blood glucose, glycosylated haemoglobin and gluconeogenic enzymes and increased plasma insulin, haemoglobin and hexokinase activity in streptozotocin diabetic rats (Latha and Pari 2003a). The elevated gluconeogenesis during diabetes was reverted to normal by the extract in enhancing the utilization of glucose through increased glycolysis. The effect of the extract was more prominent than that of glibenclamide. The methanol flower extract of *C. auriculata* was found to have potential alpha-glucosidase inhibitory activity in vitro, preferably on maltase with a low IC₅₀ value of 0.023 mg/mL and inhibited the maltase activity competitively (Abesundara et al. 2004). Oral administration of *C. auriculata* methanol extract in Sprague–Dawley rats signifi-

cantly and potently lowered blood glycemic response towards maltose ingestion which was observed at 30 minutes after dosing of 5 mg/kg, thus concurrently suppressed insulin activity. The ED₅₀ of the extract (4.9 mg/kg) clearly indicated that the antihyperglycemic effect was as potent as that of therapeutic drug, acarbose (ED₅₀ 3.1 mg/kg). In another study, oral administration of water-soluble fraction of the ethanol extract of *C. auriculata* flowers to alloxan diabetic rats significantly reduced blood glucose level and elevated plasma insulin level compared to the aqueous extract-treated rats and diabetic control (Hakim et al. 2007). Treatment with water-soluble fraction of ethanol extract and aqueous extract of *C. auriculata* flowers restored altered hyperlipidaemic parameters and enzymatic markers in diabetic animals. The water-soluble fraction of the ethanol extract exerted a more efficient antihyperglycemic effect compared to the aqueous extract. Surana et al. (2009) reported that the n-butanol fraction of the hydromethanol flower extract exhibited significant reduction in blood glucose levels and was also found effective in restoring the blood lipids and proteins to normal level. The activity was found comparable with standard drug phenformin. The flower and leaf extracts of *Cassia auriculata* exerted a significant reduction in the serum glucose and triglycerides and cholesterol levels and increase in the plasma insulin levels in alloxan-induced diabetic rats when compared to root and stem extracts (Umadevi et al. 2006).

An aqueous leaf extract of *Cassia auriculata* was found to lower the serum glucose level in normal rats and alloxan-induced diabetic rats (Sabu and Subburaju 2002). The extract was also found to inhibit the body weight reduction induced by alloxan administration. Glucose uptake and glycogen deposition studies suggested that *C. auriculata* leaf extract probably had no direct insulin-like effect which can enhance the peripheral utilization of glucose. In separate studies, oral administration of aqueous leaf extract of *Cassia auriculata* (100, 200, 400 and 600 mg/kg bw daily for 21 days) to alloxan-induced mild diabetic (MD) and severe diabetic (SD) rabbits produced dose-dependent fall in

fasting blood glucose up to 400 mg/kg dose from day 3 to day 21 (Gupta et al. 2009b). Further, a significant increase in insulin levels and fall in glycosylated haemoglobin (HbA1c) was observed in both MD and SD rabbits when treated with 400 mg/kg dose of the extract. The extract also caused a significant decrease in serum levels of triglycerides (TG), total cholesterol (TC) and low-density lipoprotein cholesterol (LDL-C) with a concomitant increase in high-density lipoprotein cholesterol (HDL-C) in MD and SD rabbits. Atherogenic indices (TG/HDL-C, TC/HDL-C and LDL-C/HDL-C) were also significantly reduced in both diabetic models of rabbits fed with the extract. Effect of the extract at 400 mg/kg dose was comparable to that of glibenclamide (600 µg/kg), a reference antidiabetic drug. Similar results were obtained with the leaf extract in streptozotocin (STZ)-induced mild diabetic (MD) and severe diabetic (SD) rats (Gupta et al. 2009a). In another study, Gupta et al. (2010) found that aqueous leaf extract of *C. auriculata*-treated mildly diabetic (MD) and severely diabetic (SD) rats showed significant reduction in fasting blood glucose. Assessment of plasma insulin and C-peptide following treatment with the leaf extract revealed significant elevation in their levels. Administration of the leaf extract enhanced the activity of hepatic hexokinase and phosphofructokinase and suppressed glucose-6-phosphatase and fructose-1,6-bisphosphatase in both MD and SD rats. A significant rise in glycogen content was also observed in both liver and muscles of leaf extract-fed MD and SD rats. Histopathological examination of pancreatic sections revealed increased number of islets and β -cells in leaf extract-treated MD as well as SD rats. The results of the study suggested that the antidiabetic effect of the leaf extract could be due to its insulinogenic action as well as through pancreatic as well as extrapancreatic action. In another recent study, supplementation of *C. auriculata* aqueous leaf extract to the streptozotocin-induced diabetic rats produced significant reduction in fasting blood glucose along with significant reversal in altered serum lipid profile and apolipoprotein B (Gupta et al. 2011). Lipid peroxidation was found to be significantly

suppressed in extract-fed diabetic rats. Significant reduction in serum levels of oxidized low-density lipoprotein, soluble vascular cell adhesion molecule and plasma fibrinogen with a concomitant elevation in serum nitric oxide was observed in diabetic rats following treatment with extract. Histopathological examination of heart myocardium of extract-treated diabetic rats revealed reversal of fatty change towards normal. The results suggested that *C. auriculata* aqueous leaf extract exhibited anti-atherosclerotic role in the diabetic state and may help to prevent the progression of cardiovascular diseases.

Gold nanoparticles (AuNPs) using *Cassia auriculata* aqueous leaf extract were synthesized, and the stabilizing and reducing molecules of nanoparticles may promote antihyperglycemic effect but required further testing (Kumar et al. 2011). Green leafy *Cassia auriculata* porridge should not be recommended as breakfast meals for diabetics because of its high GI (77) compared to other green leafy porridges (Anuruddhika and Ekanayake 2013).

Oral administration of ethanol (400 mg/kg) and aqueous extract (250, 500 mg/kg) of whole plant of *C. auriculata* to streptozotocin-induced neonatal model of non-insulin-dependent diabetes mellitus (NIDDM) rats led to suppression in elevated glucose, cholesterol and triglycerides levels (Juvekar and Halade 2006).

Diamed an herbal formulation composed of the aqueous extracts of three medicinal plants (*Azadirachta indica*, *Cassia auriculata* and *Momordica charantia*) was found to have antihyperglycaemic action in alloxan-induced experimental diabetes in rats (Pari et al. 2001). Oral administration of Diamed resulted in a significant reduction in blood glucose, glycosylated haemoglobin, and an increase in plasma insulin and total haemoglobin. Diamed also prevented a decrease in body weight.

Antihyperlipidaemic Activity

The crude extract of *C. auriculata* aerial parts displayed in-vitro inhibitory activity against pancreatic lipase with IC_{50} of 6.0 µg/mL

(Habtemariam 2013). The most active antilipase compound in the extract was kaempferol-3-*O*-rutinoside with IC_{50} value (2.9 μ M) only about twice weaker than the standard antilipase drug, orlistat (IC_{50} = 1.45 μ M). Luteolin, quercetin and rutin were found to be weak pancreatic lipase inhibitors (IC_{50} > 100 μ M), whereas kaempferol showed no activity up to 250 μ M.

Cassia auriculata flowers were found to possess antihyperlipidaemic effect in addition to antidiabetic activity (Pari and Latha 2002). Oral administration of aqueous flower extract of *C. auriculata* suppressed the elevated blood glucose and lipid levels in streptozotocin-induced diabetic rats. The effect was found to be comparable to glibenclamide. Administration of the ethanol extract of *C. auriculata* flowers to triton WR 1339 induced hyperlipidaemic rats to revert the parameters of hyperlipidaemia to normal (Vijayaraj et al. 2011, 2013). Treatment with the extract significantly reduced the total cholesterol (TC), triglycerides (TG) and low-density lipoprotein cholesterol (LDL) levels and significantly increased the high-density lipoprotein (HDL) level associated with reduction of atherogenic index in hyperlipidaemic rats. Lipid peroxidation decreased whereas the activities of superoxide dismutase, glutathione peroxidase and catalase increased in extract treated rats. Pronounced changes were comparable to the standard drug lovastatin.

Hepatoprotective Activity

The study of Kumar et al. (2002) showed that treatment with *C. auriculata* leaf extract had a lipid-lowering effect in rats with experimentally induced, alcohol-related liver damage. This was associated with a reversal of steatosis in the liver and of spongiosis in the brain. They reported that administration of *C. auriculata* leaf extract to rats with alcohol-induced hepatotoxicity significantly lowered the levels of thiobarbituric acid reactive substances (TBARS) and hydroperoxides and elevated the activities of superoxide dismutase (SOD) and catalase (CAT) and the levels of

reduced glutathione (GSH) in the liver, brain, kidney and intestine compared to unsupplemented alcohol-treated rats (Kumar et al. 2003). The leaf extract restored the serum vitamin E and vitamin C levels also to near those of the experimental control animals. Histopathological studies of the liver and brain confirmed the beneficial role of *Cassia auriculata* leaf extract.

Nephroprotective Activity

The ethanol root extract of *Cassia auriculata* at doses of 300 and 600 mg/kg body weight reduced elevated blood urea and serum creatinine and normalized the histopathological changes in the curative regimen in cisplatin-induced renal injury in male albino rats (Annie et al. 2005). In the gentamicin-induced renal injury model, the ethanol extract at a dose of 600 mg/kg body weight reduced blood urea and serum creatinine effectively in both the curative and the preventive regimen. The probable mechanism of nephroprotection by *C. auriculata* against cisplatin- and gentamicin-induced renal injury could be due to its antioxidant and free radical scavenging property.

Immunomodulatory Activity

Polyphenols derived from *Cassia auriculata* were found to boost T-cell immunity by increasing the number of T cells and B cells percentage along with enhanced proliferation of splenocytes in both resting and LPS-stimulated cells in aged rats (John et al. 2011). *Cassia* polyphenol supplementation reduced the oxidative burst activity of neutrophils in response to PMA (phorbol myristate acetate) and *Escherichia coli* activation that could potentially harm multiple biological systems in aged rats.

Neuroprotective Activity

Streptozotocin diabetic rats treated with aqueous flower extract of *Cassia auriculata* or glibenclamide

showed significant decrease in thiobarbituric reactive substances (TBARS) and hydroperoxide formation in the brain, suggesting the role of the extract in protection against lipid peroxidation-induced membrane damage by antiperoxidative efficacy (Latha and Pari 2003b).

Laxative Activity

Studies showed that the ethanol pod extract of *C. auriculata* (200 mg/kg p.o.) exhibited laxative activity in rats (Suresh et al. 2007). The ethanol extract induced an increase in gastrointestinal transit as compared to control. It was also concluded that the anthracene derivatives present could be attributed for the laxative activity.

Antipyretic Activity

The flower and leaf extracts of *C. auriculata* were reported to have antipyretic activity (Vedavathy and Rao 1991).

Herbal Drug–Drug Interaction

Studies demonstrate that a significant increase (32.5 %) in the steady state levels of theophylline occurred when this drug was administered concurrently with herbal tea-prepared dried flowers of *Cassia auriculata* (Thabrew et al. 2004b). They cautioned that herbal teas prepared from *C. auriculata* should therefore be avoided by patients treated with theophylline as these herbal teas had the potential to influence the bioavailability of the prescription drug. They also found that *C. auriculata* tea had the potential to influence the bioavailability of carbamazepine and hence its therapeutic actions. They demonstrated that in rats receiving the *Cassia auriculata* tea and carbamazepine, the blood levels of the prescription drug were significantly enhanced by 47.1 %, when compared with the levels in animals receiving only carba-

mazepine for the same time period, with no apparent changes in toxicity. Concurrent ingestion of carbamazepine with herbal teas containing *Cassia auriculata* was therefore best avoided by patients under treatment for epilepsy.

Antiplasmodial Activity

The methanol leaf extract of *C. auriculata* showed promising antiplasmodial activity against blood stage CQ-sensitive (3D7) and CQ-resistant (INDO) strains of *Plasmodium falciparum* in culture with IC₅₀ value of 14 µg/mL. The high TC₅₀ in mammalian cell cytotoxicity assay and the low IC₅₀ in antimalarial *P. falciparum* assay indicated selectivity and good resistance indices for the leaf extract.

Insecticidal Activity

Benzene root extract was found to be most potent among all extract showing comparable paralysis of *Pheretima posthuma* and death time comparable to the standard anthelmintic drug albendazole (Wadekar et al. 2011). Phytochemical analysis of the crude root extracts revealed the presence of an array of active chemical constituents such as tannins, flavonoids, glycosides, carbohydrates, steroids and triterpenoids. The petroleum ether, ethyl acetate, ethanol and aqueous extracts of *Cassia auriculata* leaves exhibited dose-dependent anthelmintic activity against the earthworm, *Eisenia foetida* (Kainsa et al. 2012). The decreasing order of activity of extracts was ethyl acetate, ethanol, petroleum ether and aqueous extracts.

Insecticidal Activity

The acetone, chloroform, ethyl acetate, hexane, methanol and petroleum ether extracts of leaf, flower and seed of *Cassia auriculata* showed moderate larvicidal effects; however, the highest

mortality was found in leaf petroleum ether, flower methanol extracts of *C. auriculata*, against the larvae of *Anopheles subpictus* (LC_{50} =44.21, 44.69 ppm; LC_{90} =187.31, 188.29 ppm, respectively) and against the larvae of *Culex tritaeniorhynchus* (LC_{50} =69.83, 51.29 ppm; LC_{90} =335.26, 245.63 ppm, respectively) (Kamaraj et al. 2009).

The leaf ethyl acetate and flower methanol extracts of *C. auriculata* exerted highest mortality of the larvae of cattle tick *Rhipicephalus (Boophilus) microplus*; the leaf methanol exhibited antiparasitic activity against adult hematophagous fly, *Haemaphysalis bispinosa* (Kamaraj et al. 2010).

Safety/Toxicity Studies

Animal studies by Puranik et al. (2011) found that the traditional hydroalcoholic extract and technology-based supercritical extract of *Cassia auriculata* (CA) seeds to be pharmacologically safe and did not show any significant adverse reactions at the tested doses (250 mg to 1,000 mg/kg). The traditional hydroalcoholic extract did not show any significant effect on pharmacokinetics; however, the technology-based supercritical extract caused a significant reduction in absorption of metformin when co-administered. No rat mortality was observed during the treatment period of 12 weeks in either the control or treated groups. No significant change in total bilirubin, TC, TG, glucose and creatinine was observed. There was no significant difference between both systolic and diastolic blood pressure between CA extract-dosed animals and controls. ECG variables like heart rate (R-R interval), QT interval (diastolic dysfunction) and ventricular hypertrophy (R wave amplitude) were normal in all the groups.

Cassia auriculata was found to have pyrrolizidine alkaloids (Arseculeratne et al. 1981). Feeding trials in rats with materials from the plant produced liver lesions—disruption of the centrilobular veins, congestion or haemorrhage in the centrilobular sinusoids, and centrilobular or focal hepatocellular necrosis—and

histopathology in the lungs and kidneys which were in accord with the action of pyrrolizidine alkaloids. The researchers suggested that the consumption of herbal medicines that contain pyrrolizidine alkaloids could contribute to the high incidence of chronic liver disease including primary hepatocellular cancer in Asian and African countries.

Traditional Medicinal Uses

The leaves, flowers, seeds, roots and bark are used for medicinal purposes in traditional medicine. The plant is used for the treatment of skin diseases, asthma, conjunctivitis and renal disorders by the tribal communities of the Chittoor district of Andhra Pradesh (Vedavathy et al. 1997). The Lambadis use the leaves for bone fractures; the Chenchus use the seeds to treat inflammations, diarrhoea, infertility, fever, migraine, night blindness, scorpion sting, leucorrhoea, ulcers and fissures in the mouth, and the stem and root for renal ailments; the Yanadis use the root bark and stem bark for stomach ache and earache. The leaves and fruit are ground into a paste and given as pills orally with limewater for leucorrhoea and menorrhoea in women by the Adivasis tribe of the Eastern Ghats, Andhra Pradesh (Ratnam and Raju 2005). The leaves are used in folk medicine for scorpion bites by the Chencu and Yanadi tribes in Gundla Brahmeswaram Wildlife Sanctuary, Andhra Pradesh (Ratnam and Raju 2008). They also use the whole plant for leucorrhoea and menorrhoea, similarly prepared and the pills are taken orally with milk. In South Travancore, India, the tribal communities use the leaves as a paste with vinegar for external application for various skin diseases (Jeeva et al. 2007). The indigenous communities of Kanyakumari district of Tamil Nadu use a dried leaf paste in vinegar as application on skin diseases once a day till cured (Kingston et al. 2009). In the Haveri district of Karnataka state, India, the village folks use tender cassia leaves mixed with lime in tablet form for stomach ache (Nagnur et al. 2009). Leaves and flowers are used for diabetes and

religious function by the community in the sacred grove of Pallapatti in the Madurai district of Tamil Nadu, India (Ganesan et al. 2009). Traditional healers in the Kancheepuram district of Tamil Nadu prescribe ingestion of the dried flower powder mixed with goat milk to prevent white discharge (Muthu et al. 2006).

The roots and bark are astringent and are used for gargles, as an alterative, and to cure skin diseases, eye troubles and rheumatism (CSIR 1950; Chopra et al. 1986; Duke 1981; Rahmansyah 1991). A decoction of the flowers and the seeds is recommended for diabetes; seeds are used to cure eye diseases, gonorrhoea and gout. In Tanzania the plant is used to treat impotence, which may be related to diabetes (Jansen 2005). Leaves and fruits serve as an anthelmintic and diuretic.

Other Uses

The plant is utilized for green manuring in India and is used for revegetating erodible and sodic soils. The bark is used in India to stupefy fish. The bark yields a valuable tanning material for heavy hides, and goatskin and sheepskin, a black dye and bast fibres can be made into ropes. Handles of small tools can be made from the wood. Branches are used as chewing sticks and toothbrushes. In southern India the flowers are used as a fast yellow dye for leather. In Gujarat, India, the flower buds are used with madder roots (*Rubia cordifolia*) in the galling process prior to dyeing cotton cloth and chintzes red, pink or purple. Boiled seeds are an important ingredient in indigo vats where bacterial fermentation converts the insoluble indigo into soluble leuco-indigo, facilitating the impregnation of the dye by textile fibres.

Comments

The plant is propagated from seeds. Acid scarification or manual scarification of seeds will facilitate germination. The tree also produces root suckers freely.

Senna siamea

Scientific Name

Senna siamea (Lam.) Irwin & Barneby

Synonyms

Cassia arayatensis sensu Naves, non Litv., *Cassia arborea* Macfad., *Cassia florida* Vahl, *Cassia gigantea* DC., *Cassia siamea* Lam., *Cassia siamea* Lam. var. *puberula* Kurz, *Cassia sumatrana* DC., *Cassia sumatrana* Roxb., *Chamaefistula gigantea* G. Don, *Sciacassia siamea* (Lam.) Britt. ex Britt. & Rose, *Senna sumatrana* Roxb.

Family

Fabaceae, also placed in Caesalpiniaceae

Common/English Names

Blackwood Cassia, Bombay Blackwood, Cassod, Cassod Tree, Iron Wood, Kassod Tree, Pheasant Wood, Siamese Cassia, Siamese Senna, Siamese Shower, Thai Cassia, Thai Copper Pod, Thailand Shower, Yellow Cassia

Vernacular Names

Amharic: Yeferenji Digita

Tongan: Kasia

Vietnamese: Muồng Đen, Muồng Xiêm

Origin/Distribution

The species is native to South and Southeast Asia from India through to Malaysia and much of Malesia. It has been introduced to other humid tropical countries.

Agroecology

S. siamea will grow in a range of climatic conditions but is particularly adapted to the warm lowland tropics with a monsoon climate, with mean annual temperatures of 20–31°C and mean annual rainfall of 500–2,800 mm. It is found growing from sea level to 1,000 m altitude. It does not grow well in at altitudes above 1,300 m and will not survive in areas where the temperate falls below 10 °C. It tolerates seasonal flooding and exposure to strong winds but is cold, drought and salinity intolerant. It thrives on deep, well-drained soil rich in organic matter but will grow on degraded lateritic soils provided drainage is not impeded.

Edible Plant Parts and Uses

The young leaves have a bitter taste; young tender pods and inflorescences (buds/open flowers) are edible (Facciola 1990; Padumanonda and Gritsanapan 2006; Maisuthisakul et al. 2008; Kaisoon et al. 2011). The young leafy shoots (Plate 3) and young inflorescences are bundled and sold in markets as vegetables (Jacquat 1990). The leaves and flowers are popularly used in soups and in the Thai curry dish known as ‘kaeng khi-lek’ which is prepared with and without

coconut milk (Monkheang et al. 2011). The fresh young leaves are boiled with water 2–3 times to get rid of the bitterness and to reduce the toxic barakol content before the boiled mush is used for curry. They are also pickled in brine. In Sri Lanka, the flowers and young fruits are used in curries.

Botany

A medium-sized, evergreen, much-branched perennial tree to 30 m tall with a straight trunk of 30 cm diameter with gray bark and a spreading crown of dense foliage (Plate 1). The leaves are alternate and pinnate, 23–33 cm long, and made up of 5–14 pairs of lanceolate, oblong or ovate-elliptic leaflets (Plates 1, 2 and 3), 3–7 cm long and 12–20 mm wide, abaxially finely pubescent, adaxially smooth and glabrous, base rounded and apex obtuse, borne on 25–40 mm long, terete petioles with caducous, minute subulate stipules.

Plate 1 Flowers, leaves and pods

Plate 2 Pinnate leaves

Plate 3 Tender leafy shoots sold as vegetables

Flowers occur in many-flowered, axillary or terminal, 40 cm long, racemose panicles (Plate 1). Flower 3 cm across, pedicellate, bisexual, zygomorphic, pentamerous, hypogynous; sepals imbricate, suborbicular, obtuse at the apex, pubescent outside; petals subequal, broadly obovate, bright yellow, shortly clawed; stamens 10, 7 fertile, accrescent towards the abaxial side of the flower, anther with apical pores; ovary superior, sessile, pubescent, linear and slightly curved. The fruits are pendant, linear, flat and often slightly curved legumes, 5–30 cm long, 12–20 mm wide, coriaceous or subwoody, and dark brown and dehiscent when ripe. Each fruit contains about 25 subglobose to ovate and laterally flattened seeds with a glossy, smooth, dark-brown testa.

Nutritive/Medicinal Properties

Flower Nutrient/Phytochemicals

Proximate nutrient composition of the edible flowers was reported in g/100 g edible portion as moisture 74.8 %, ash 5.6 g, protein 19.4 g, fat 1.6 g, carbohydrate 34.9 g, energy 231.7 kcal, dietary fibre 38.5 g, Ca 55.6 mg, Fe 6.93 mg and vitamin C 483.3 mg (Maisuthisakul et al. 2008). Antioxidant activity (DPPH radical scavenging activity) was 2.4 (1/EC₅₀), total phenolics 51.5 mg GAE/g dry basis (db) and total flavonoids 24.8 mg RE/g db. The soluble phenol acids (per g dry weight) identified in *Cassia siamea* flower extract were gallic acid 30.3 µg, protocate-

chuic acid 638.4 µg, *p*-hydroxy benzoic acid 29.4 µg, vanillic acid 4.2 µg, chlorogenic acid 20.64 µg, caffeic acid 14.93 µg, syringic acid 16.0 µg, *p*-coumaric acid 17.5 µg, ferulic acid 11.6 µg, sinapic acid 10.4 µg and total phenolic acids 793.3 µg (Kaisoon et al. 2011). The flowers contained 455.5 µg total bound phenolic acids made up of *p*-hydroxy benzoic acid 8.8 µg, vanillic acid 3.4 µg, syringic acids 4.7 µg, *p*-coumaric acid 93.3 µg, ferulic acid 128.6 µg and sinapic acid 216.8 µg. The flowers contained 133.7 µg total soluble flavonoid made up of rutin 64 µg, myricetin 4.56 µg, quercetin 61.9 µg and kaempferol 3.21 µg and bound flavonoid 52.9 µg made up of rutin 32 µg, quercetin 10.9 µg and apigenin 10 µg. The DPPH radical scavenging activity (% inhibition) of soluble and bound phenolic fraction of the flower was 97.64 and 38.30 %, respectively. Bound phenolics exhibited lower antioxidant activity than soluble ones. The reducing potential of the soluble and bound phenolic fraction of the flower as evaluated by FRAP (ferric reducing antioxidant power) assay (mmol FeSO₄/100 g dry weight) was 7.30 and 26.6 mmol, respectively.

A chromone named chromone 1 was isolated from the flowers (Arora et al. 1971). Cassiadine, a chromone alkaloid, and (+)-6-hydroxy-mellein, a dihydroisocoumarin, were isolated from the flowers (Biswas and Mallik 1986). Three new alkaloids, cassiarins C–E, and a new chromone, 10,11-dihydroanhydrobarakol, were isolated from the flowers (Oshimi et al. 2009). Cassiarin D was a dimeric compound consisting of 5-acetonyl-7-hydroxy-2-methylchromone and cassiarin C, and cassiarin E was a dimer of cassiarins A and C. The alkaloid cassiarin F was isolated from the flowers (Deguchi et al. 2011).

Seed/Fruit Phytochemicals

A water-soluble polysaccharide composed of D-galactose, D-mannose and D-xylose in a molar ratio 3:6:2 was isolated from *C. siamea* seeds (Khare et al. 1980). Hydrolysis of the methylated polysaccharide furnished five methylated sugars (I) 2, 3 di-*O*-methyl D-xylose, (II) 2, 3 di-*O*-methyl

D-mannose, (111)2, 3, 4-tri-O-methyl D-galactose, (IV) 2, 3, 6-tri-O-methyl D-mannose and (V) 2, 3, 4, 6-tetra-O-methyl D-galactose in the molar ratio 4:4:2:8:4, while partial acidic hydrolysis yielded five oligosaccharides (I) epimelibiose, (II) manobiose, (III) mannotriose, (IV) mannosylgalactobiose and (V) xylotetraose. *Cassia siamea* seed oil was found to be a minor source of vernolic and cyclopropenoid fatty acids; it contained palmitic (19.0 %), stearic (7.6 %), oleic (11.6 %), linoleic (42.7 %), malvalic (2.0 %), sterculic (3.1 %) and vernolic (14.0 %) acids (Daulatabad et al. 1988).

A sodium salt of a natural 2-methylchromone was isolated from pods of *C. siamea* (Reddy et al. 1976). An anthraquinone, 1-desmethylchrysobutusin-2-O-glucoside, was isolated from the fruit (Abdallah et al. 1994).

Leaf Nutrients/Phytochemicals

Leaves of *Cassia siamea* together with leaves of 3 other species out of 127 species were classified in the very high class group for both TEAC (Trolox equivalent antioxidant capacity) and SOS (superoxide scavenging) activity. TEAC values on a dry weight basis ranged from 0 to 2,105 µmol TE/g, and SOS values ranged from 0 to 6,206 µmol ascorbate equivalent (AE)/g (Yang et al. 2006). Kuo (2002) reported the young leafy shoot of *C. siamea* to have 20 g dry matter, 1.29 g fibre, 0.92 g sugar, 5.92 g protein, 3.48 mg vitamin C, 97 mg β-carotene, 26 mg Ca and 1.26 mg Fe. The proximate nutrient composition of cassod leaves was reported as follows: moisture content 46.01 %, protein 4.01 %, crude fibre 12.36 %, ash 17.93 %, carbohydrate 7.67 %, crude fat 12.02 % and minerals in ppm, potassium 812, calcium 932, sodium 612, magnesium 876, manganese 35.10, phosphorus 10.84, iron 112, copper 0.84 and lead 0.34 ppm (Smith 2009). Saponins, anthraquinones, phlobatannins and alkaloids were detected in the ethanol leaf extract and also present were antinutrients phytate, tannin and oxalate in trace amounts.

A dioxaphenylene derivative was isolated from *Cassia siamea* leaves and named barakol

and its structure determined as 3α,4-dihydro-3α,8-dihydroxy-2,5-dimethyl-1,4-dioxaphenylene (Hassanali et al. 1968). From the leaves were isolated β-sitosterol, cassiamin A, physcion, chrysophanol, *p*-coumaric acid, apigenin-7-O-galactoside (thalictin), and a new chromone cassiachromone with the structure 2-methyl-5-acetyl-7-hydroxy-chromone (Wagner et al. 1978). Barakol, apigenin and β-sitosterol were isolated from the leaves (Krishna Rao and Murthy 1978). Isoquinoline alkaloids, siamine and siaminines A, B and C, were isolated from the leaves (El-Sayyad et al. 1984). An isoflavone glycoside 2',4',5,7-tetrahydroxy-8-C-glucosylisoflavone (2'-hydroxygenistein 9-C-glucoside) was isolated from the leaves (Shafiullah et al. 1995).

Luteolin; cassia chromone (5-acetyl-7-hydroxy-2-methylchromone); 5-acetyl-7-hydroxy-2-hydroxymethyl-chromone; 4-(*trans*)-acetyl-3,6,8-trihydroxy-3-methyldihydronaphthalenone; and 4-(*cis*)-acetyl-3,6,8-trihydroxy-3-methyldihydronaphthalenone were isolated from the leaves (Ingkaninan et al. 2000). Two alkaloids cassiarins A and B were isolated from the leaves (Morita et al. 2007). Chrobisiamone A, a new bischromone, was isolated from the leaves (Oshimi et al. 2008). Cyclization of 5-acetyl-7-hydroxy-2-methylchromone in the presence of ammonium acetate resulted in generation of cassiarin A. Six compounds were isolated from the leaves and identified as 2-methyl-5-acetyl-7-hydroxy-chromone (1), 4-*cis*-acetyl-3,6,8-trihydroxy-3-methyl-dihydronaphthalenone (2), emodin (3), physcion (4), β-amyrin (5) and β-sitosterol (6) (Xue et al. 2010). A triterpene, lup-20(29)-en-1β-3β-diol, was isolated from the plant (Tripathi et al. 1992).

Fresh young leaves of *S. siamea* contained 0.4035 % w/w barakol (Padumanonda and Gritsanapan 2006). Barakol was extracted as pure lemon-yellow crystals from young *S. siamea* leaves with 0.1 % yield (Padumanonda et al. 2007). Barakol content in young leaves, mature leaves and young flowers were 1.67, 0.78 and 1.43 % dry weight, respectively. Total anthraquinone glycosides and total anthraquinones, calculated as rhein, in the fresh young leaves were

0.0523 and 0.0910 % w/w, respectively (Sakulpanich and Gritsanapan 2009). The first and second boiled filtrates contained total anthraquinone glycosides 0.0334 and 0.0031 % fresh weight, respectively. The first boiled leaves contained 0.0161 % fresh weight, and the second boiled leaves contained non-detected amount. Total anthraquinone contents in the first and second filtrates and the first and second boiled leaves were found to be 0.0721, 0.0069, 0.0167 % fresh weight and non-detected amount, respectively. Four new alkaloids, cassiarins G, H, J and K (1–4), were isolated from the leaves, (Deguchi et al. 2012).

Stem/Wood Phytochemicals

From heartwood, a new bianthraquinone, 4,4'-bis(1,3-dihydroxy-2-methyl-6,8-dimethoxy anthraquinone), along with 1,1'-bis(4,5-dihydroxy-2-methyl anthraquinone), chrysophanol and emodin were isolated (Singh et al. 1992). From the stem bark, 19 α , 24-dihydroxyurs-12-ene-28-oic acid-3-O- β -D-xylopyranoside along with anthraquinones, namely, chrysophanol and physcion, were isolated (Singh and Agrawal 1994).

From the stem, three anthraquinone compounds were isolated and identified as chrysophanol, chrysophanol-1-O- β -D-glucopyranoside and 1-[(β -D-glucopyranosyl-(1 \rightarrow 6)-O- β -D-glucopyranosyl)oxy]-8-hydroxyl-3-methyl-9,10-anthraquinone (Lü et al. 2001b), and a chromone glycoside, 2-methyl-5-propyl-7, 12-dihydroxy chromone-12-O- β -D-glucopyranoside (Lü et al. 2001b). Five additional compounds were isolated from the stem and identified as β -sitosterol, sucrose, *n*-octacosanol, 2-methyl-5-(2'-hydroxypropyl)-7-hydroxy-chromone-2'-O- β -D-glucopyranoside and piceatannol (Lü et al. 2003). Emodin and lupeol were isolated from the ethyl acetate fraction of the stem bark extract (Ajaiyeoba et al. 2008). Triterpenes (lupeol, oleanolic acid, ursolic acid, friedelin, betulin), flavonoids (apigenin, kaempferol, luteolin), anthraquinones (emodin) and phytosterols (stigmasterol, β -sitosterol) were reported in the stem bark (Nsonde Ntandou et al. 2010).

Root Phytochemicals

Anthraquinones, chrysophanol, emodin, and two bianthraquinones, cassiamin A and cassiamin B (Koyama et al. 2002a), another two bianthraquinones (1,1',3,8,8'-pentahydroxy-3',6-dimethyl[2,2'-bianthracene]-9,9',10,10'-tetrone and 7-chloro-1,1',6,8,8'-pentahydroxy-3,3'-dimethyl[2,2'-bianthracene]-9,9',10,10'-tetrone, respectively (Koyama et al. 2001a), were isolated from the root bark.

Antioxidant Activity

The alcoholic flower extract of *C. siamea* was found to contain a large amount of polyphenols and also exhibited an immense reducing ability (Kaur et al. 2006). At a concentration of 250 μ g/mL, 96 % of DPPH radicals and at 500 μ g/mL, 42.7, 32.7 and 64.5 % of O $^{2-}$, H $_2$ O $_2$ and NO, respectively, were scavenged by the extract. The extract also inhibited OH radical-induced oxidation of protein (bovine serum albumin) and lipid peroxidation in murine hepatic microsomes. The extract displayed significant antioxidant activity in acute oxidative tissue injury animal model caused by CCl $_4$ -induced hepatotoxicity. Oral administration of the extract at a dose of 50–150 mg/kg of body weight significantly protected from CCl $_4$ -induced elevation in aspartate aminotransaminase (AST) and alanine aminotransaminase (ALT), in the serum; elevation in hepatic lipid peroxidation; depletion of hepatic glutathione (GSH); and decrease in the activities of hepatic antioxidant enzymes: superoxide dismutase (SOD), glutathione peroxidase (GPX) and catalase (CAT). The extract also protected against histopathological changes produced by CCl $_4$ such as necrosis, fatty changes and ballooning degeneration. The findings suggested that the alcoholic extract of *C. siamea* flowers had potent antioxidant activity against free radicals, prevented oxidative damage to major biomolecules and afforded significant protection against oxidative damage in the liver.

Antitumour Activity

Antraquinone monomers isolated from *Cassia siamea* showed higher antitumour-promoting activity than that of bianthraquinones in inhibiting Epstein–Barr virus activation (Koyama et al. 2001b). Emodin and cassiamin B, isolated from *Cassia siamea*, exhibited marked antitumour-promoting effect on two-stage carcinogenesis test of mouse skin tumours induced by 7,12-dimethylbenz[*a*]anthracene as an initiator and 12-*O*-tetradecanoylphorbol-13-acetate (TPA) as a promoter by topical application (Koyama et al. 2002b). In addition, emodin exhibited potent inhibitory activity on two-stage carcinogenesis test of mouse skin tumours induced by nitric oxide donor, (+/–)-(*E*)-methyl-2-[(*E*)-hydroxyimino]-5-nitro-6-methoxy-3-hexeneamide as an initiator and TPA as a promoter.

Antiplasmodial Activity

Crude hot water extracts of *Cassia siamea*, *Jatropha gossypifolia* and *Pavetta crassipes* exhibited 100 % inhibition in vitro against *Plasmodium falciparum* (Gbeassor et al. 1989). Two alkaloids cassiarins A and B isolated from the leaves showed antiplasmodial activity; cassiarin A showed potent activity (Morita et al. 2007). Cassiarin A isolated from *C. siamea* leaves exhibited potent antimalarial activity against *Plasmodium falciparum* in vitro as well as *P. berghei* in vivo (Morita et al. 2009). Based on the premise that interactions of parasitized red blood cells (pRBCs) with endothelium in aorta were especially important in the processes involved in the pathogenesis of severe malaria, they found that cassiarin A showed vasorelaxation activity against rat aortic ring, which may be related with nitric oxide (NO) production. NO had been reported to reduce cytoadherence of pRBC to vascular endothelium. Similarly, a series of a hydroxyl and a nitrogen-substituted derivatives and a dehydroxy derivative of cassiarin A having potent antimalarials against *P. falciparum* with vasodilator activity reduced

cytoadherence of pRBC to vascular endothelium. These derivatives showed more potent vasorelaxant activity but not higher inhibition of *P. falciparum* in vitro. The results suggested that cassiarin derivatives may be promising candidates as antimalarials with different mode of actions.

Emodin and lupeol, isolated from the stem bark, were found to be the active principles responsible for the antiplasmodial property with IC₅₀ values of 5 µg/mL, respectively, against the multi-resistant strain of *Plasmodium falciparum* (K1) (Ajaiyeoba et al. 2008). Chrobisiamone A, a new bischromone isolated from the leaves, exhibited antiplasmodial activity (Oshimi et al. 2008). Three new alkaloids, cassiarins C–E (1–3), and a new chromone, 10,11-dihydroanhydrobarakol (4) isolated from the flowers, showed moderate antiplasmodial activity against *Plasmodium falciparum* 3D7 (Oshimi et al. 2009). The alkaloid cassiarin F from the flowers showed antiplasmodial activity against *Plasmodium falciparum* (Deguchi et al. 2011). Four new alkaloids, cassiarins G, H, J and K (1–4), isolated from the leaves, showed moderate antiplasmodial activity against *Plasmodium falciparum* 3D7 (Deguchi et al. 2012).

Cardioprotective Activity

Pretreatment with barakol (10 mg/kg i.v.) from *C. siamea* leaves reduced the incidence of aconitine-induced ventricular fibrillation (VF) and ventricular tachycardia (VT) as well as mortality of rats (Chen et al. 1999). It was found that the mechanisms of the protective effects of barakol on aconitine-induced cardiac toxicity may relate to the prevention of intracellular Na⁺ accumulation.

Vasodilating Activity

In rings cut from rat superior mesenteric arteries precontracted with phenylephrine, cassiarin A from *C. siamea*, induced a concentration-dependent relaxation (Matsumoto et al. 2010).

It was found that the vasodilating effect of cassiarin A may be mediated by endothelial nitric oxide and may occur partly via BK(Ca)-channel activation.

CNS (Anti-insomnia, Analgesic, Anxiolytic) Activities

Animal studies showed that barakol, active compound from *S. siamea*, had anxiolytic properties similar to diazepam but differed from diazepam in that it also increased exploratory and locomotor behaviour, as shown by the number of rears and total arm entries in the elevated plus-maze test (Thongsaard et al. 1996). However, studies by Fiorino et al. (1998) found that barakol (0–20 mg/kg) exhibited no evidence of its anxiolytic effects in either of two pharmacologically validated tests of rat anxiety: the plus-maze or shock-probe burying tests.

Luteolin from *Senna siamea* was found to be an antagonist at the adenosine A(1) receptor binding activity with a $K(i)$ value in the low micromolar range (Ingkaninan et al. 2000). Abundant evidence showed that the sleep-inducing effects were mediated locally in the basal forebrain through the adenosine A1 receptor (Alanko et al. 2004). They found that G-protein activity was increased in the cortex but not in the basal forebrain during the first hours of sleep deprivation, suggesting different A1 receptor-mediated responses to increasing adenosine concentrations in different brain areas.

Studies showed that barakol, from *C. siamea*, reduced spontaneous locomotor activity, increased the number of sleeping mice and prolonged the thiopental-induced sleeping time, indicating a sedative effect (Sukma et al. 2002). At a high dose (100 mg/kg, i.p.), barakol slightly prolonged the latency of clonic convulsion induced by the convulsant, picrotoxin, suggesting that the sedative effect may not be induced via the GABA or glycine systems. There was no evidence of an anxiolytic effect of barakol in the plus-maze test. However, barakol (25–100 mg/kg, i.p.) could suppress

methamphetamine (1 mg/kg, i.p.)-induced hyperlocomotor activity in a dose-dependent manner, indicating an effect on the dopaminergic system. The results indicated that the CNS inhibitory effect of barakol on dopamine release may account for the blocking effect of barakol on the striatum-related behaviour induced by methamphetamine. Acute and chronic oral administration of barakol (10, 30 and 100 mg/kg, p.o.) had no anxiolytic and locomotor effects on male Wistar rats (Deachapunya and Thongsaard 2009). However, it exerted a sedative effect as shown by a reduction in the directed exploratory behaviours.

Studies showed that intraperitoneal administration of low-dose (25 mg/kg) and high-dose (100 mg/kg) barakol resulted in sleeping behaviour in Long-Evans hooded rats, substantiating the use of the cassod leaves for insomnia commonly prescribed in Thai traditional medicine (Bulyalert 2011). The acetic acid-induced writhing test in mice showed that ethanol leaf extract of *Senna siamea* at the dose of 500 mg/kg exhibited significant inhibition of writhing reflex by 61.98 % while the standard drug diclofenac Na inhibition was found to be 85.95 % at a dose of 25 mg/kg body weight (Momin et al. 2012).

Antiinflammatory and Analgesic Activity

At the doses used (100, 200 and 400 mg/kg), ethanol and water extracts of *Cassia siamea* stem bark showed significant and dose-dependent analgesic and antiinflammatory effects in the hot-plate test, paw pressure and carrageenan-induced paw oedema tests (Nsonde Ntandou et al. 2010). None of the extracts had cytotoxic activity on KB and Vero cell lines, and the most active extracts (CSE3 and CSE4) had no acute toxicity. These activities were attributed to the presence of triterpenes (lupeol, oleanolic acid, ursolic acid, friedelin, betulin), flavonoids (apigenin, kaempferol, luteolin), anthraquinones (emodin) and phytosterols (stigmasterol, β -sitosterol) in the stem bark.

Antiviral Activity

Seven new chromones, siamchromones A–G (1–7), and 12 known chromones (8–19) were isolated from *Cassia siamea* stems (Hu et al. 2012). Compound 6 showed anti-tobacco mosaic virus (anti-TMV) activity with an inhibition rate of 35.3 % and IC_{50} value of 31.2 μ M, which was higher than that of the positive control, ningnamycin. Compounds 1, 10, 13 and 16 showed anti-TMV activities with inhibition rates above 10 %. Compounds 4, 6, 13 and 19 showed anti-HIV-1 (anti-human immunodeficiency virus-1) activities with therapeutic index values above 50.

Antimicrobial Activity

The ethanol extracts of *C. siamea*, *Syzygium jambolanum* and alga *Caulerpa scalpelliformis* exhibited antifungal activity at 100 mg/mL against *Candida albicans*, *Candida glabrata*, *Candida tropicalis*, *Candida krusei*, *Candida parapsilosis* and *Candida guilliermondii* (Prabhakar et al. 2008). The ethanol leaf extracts showed the highest activity at 40 mg/mL concentration against *Salmonella typhi* followed by acetone extracts, while the aqueous extracts showed the lowest activity (Doughari and Okafor 2008). The MIC and MBC values of the crude extracts (1–3 mg/mL) were comparable to those of the tested antibiotics (ampicillin, chloramphenicol, cotrimoxazole and ciprofloxacin). Purification of the ethanol extract showed that the ethyl acetate fraction possessed the highest activity followed by *n*-butanol fraction while the chloroform fraction did not show any activity at 20 mg/mL. The ethanol leaf extract of *Senna siamea* exhibited antibacterial activity against *Pseudomonas aeruginosa* at concentration of 500 μ g/disc in comparison with the standard kanamycin (Momin et al. 2012).

Secretagogue Activity

Studies demonstrated that barakol stimulated bumetanide-sensitive chloride secretion in rat

colon (Deachapunya et al. 2005a). The effect of barakol was partly mediated by the stimulation of submucosal nerves and through the release of cyclooxygenase metabolites. The results elucidated the underlying mechanism of barakol as a secretagogue in mammalian colon.

Purgative Activity

Barakol was found to have purgative effects (Deachapunya et al. 2005b). Barakol extract increased the force of spontaneous muscle contractions in the rat ileum in a concentration-dependent manner. Pretreatment of muscle strips with barakol (1 mM) significantly decreased the inhibitory effect of norepinephrine by 60 %, but not that of dopamine. Its ability to potentiate atropine- and saxitoxin-sensitive contractions and inhibit the antimotility actions of norepinephrine suggested that barakol may increase longitudinal smooth muscle contractions by decreasing the inhibitory effect of norepinephrine on excitatory cholinergic motor neurons. The authors concluded that barakol may produce a purgative action in small intestine which may be clinically important in patients with intestinal hypomotility disorders.

Antidiabetic Activity

Oral administration of cassod leaf extracts at doses of 250 and 500 mg/kg for 3 weeks significantly improved blood glucose levels and body weights in normal and streptozotocin-induced diabetic rats (Kumar et al. 2010). Daily oral treatment with the extract also resulted in significant reduction of serum cholesterol and triglycerides and improvement in HDL cholesterol level.

Mosquitocidal Activity

The leaf methanol extract of *C. siamea* exhibited 100 % mortality against *Anopheles stephensi* (malaria vector) and *Culex quinquefasciatus*

(filariasis vector) after 48-hour exposure, suggesting that the extract has the potential to be used as an ideal eco-friendly approach for the control of both mosquito vectors (Kamaraj et al. 2011).

Laxative Activity

Studies showed that the process of preparation of Khi Lek curry by boiling *S. siamea* young leaves twice with water reduced total anthraquinone glycosides content by more than 75 %, confirming the traditional use of Khi Lek curry as a very mild laxative drug (Sakulpanich and Gritsanapan 2009). The fresh or dried leaves are used traditionally for constipation in Thailand (Monkheang et al. 2011).

Barakol Toxicity Studies

Studies showed that the process of preparation of Khi Lek curry by boiling *S. siamea* young leaves twice with water was found to reduce barakol content up to 90 % and thus lowering the tendency to cause liver toxicity (Padumanonda and Gritsanapan 2006). Fresh young leaves contained 0.4035 % w/w barakol. The contents of barakol in the first and second boiled filtrates were 0.2052 and 0.1079 % fresh weight, while the first and second boiled leaves samples were 0.1408 and 0.0414 % fresh weight, respectively. This may explain the reason why Thai Khi Lek curry had not caused hepatotoxicity, unlike *S. siamea* leaves consumed as a powdered capsule.

Hongsirinirachorn et al. (2003) studied the adverse effects of barakol in 12 healthy Thai patients, aged 29–81 years (mean 52.5) with neither a history of chronic liver disease nor known hepatotoxic substance ingestion, who took barakol for 3–180 days (mean 76.9). Eight of them were admitted with the first episode of anorexia and jaundice for 4–60 days after taking 20–40 mg/day (2–4 tablets) of barakol. The mean total bilirubin was 5.7 mg/dL, and liver function test revealed moderate to severe hepatitis (aspartate amino transferase (AST) range 111–1,473 U/L: mean=692). Histopathological

findings were in accord with interface hepatitis. Their symptoms and liver function completely improved within 2–20 weeks (mean 5.9) after barakol abstinence.

Barakol was hepatotoxic in mice, causing liver injury when administered in a single dose (100, 200, 300 and 400 mg/kg, p.o.) and repeated doses (100, 200 and 300 mg/kg/day, p.o., 28 days) for acute and subacute toxicity studies, respectively (Devakul Na Ayutthaya et al. 2005). The acute and subacute hepatotoxic findings included the increase in total bilirubin, AST and ALT concentrations and the decrease in cholesterol, triglyceride and glucose levels which corresponded to the histopathological examination showing the hydropic swelling of hepatocytes, scattered degree of necrotic cells around central vein spreading to periportal zone and finally apoptotic cell death around centrilobular zone spreading to periportal area. The degree of the severity of barakol-induced liver injury was dose and time dependent. There were signs of liver regeneration and recovery in all doses of barakol treatment. A 6-month chronic toxicity study of powdered cassod leaves in Wistar rats showed that at the doses of 200 and 2,000 mg/kg bw/day, the levels of bilirubin were significantly increased compared to control rats (Chavalittumrong et al. 2012). A dose-dependent increase of the incidence of hepatic lesion, namely, degeneration and necrosis, was found at every dose level in both male and female animals. It appeared that male rats were more susceptible to the hepatotoxic effect of cassod than female rats. Reduction of the hepatic damage of the recovery group suggested that the hepatotoxic effect of *C. siamea* was reversible when the drug was stopped for only 14 days.

Treatment with barakol decreased cell viability in a concentration- and time-dependent manner with an IC₅₀ value of 1.5 mM in 24-h-treated mouse embryonal carcinoma P19 cells (Wongtongtair et al. 2011). Barakol-induced cytotoxicity was due to a significant increase in the number of apoptotic cells. The mechanism of barakol-mediated toxicity in P19 cells was mainly attributed with the ROS generation, followed by the imbalance of the Bax/Bcl-2 ratio,

and caspase-9 activation leading to apoptotic cell death. Pretreatment of cells with *N*-acetyl-L-cysteine could antagonize the toxicity produced by barakol.

Subchronic toxicity studies showed that *S. siamea* stem extract significantly increases the body weight and feed intake of the male Wistar rats but did not significantly affect haematological parameters, total protein and albumin levels, serum glucose, triglycerides, cholesterol and the markers of kidney function (creatinine, urea, potassium, sodium and chloride) (Mohammed et al. 2012). However, levels of serum liver enzymes (alkaline phosphatase (ALP), alanine aminotransaminase (ALT) and aspartate aminotransaminase (AST)) were significantly different from the normal control group. The quantitative determination of saponins, alkaloids, total polyphenolics and flavonoids in (g/g) were found to be 0.07, 0.05, 0.92 and 0.06, respectively. These results may explain the use of *S. siamea* stem bark in folk medicine due its less toxic effect.

Traditional Medicinal Uses

The plant is commonly used in traditional medicine to treat hypertension, malaria and diabetes mellitus (Mohammed et al. 2012). In Burkina Faso, a decoction of the leaves with lemon juice is used for the treatment of fevers (Fowler 2006). In northern Nigeria, the tree is very popular for its local usage in the treatment of typhoid fever. In Kampuchea, a hardwood decoction is used against scabies. The fruit and seeds have been used to treat intestinal worms. In Thailand, the leaves and flowers are used as a remedy for insomnia, as laxative for constipation and as appetite stimulant and digestive stimulant; flower and root decoctions are used to treat anxiety, nervousness and stress, and wood decoction for fever (Thongsaard et al. 1996; Sukma et al. 2002; Deachapunya et al. 2005a; Sakulpanich and Gritsanapan 2009; Bulyalert 2011; Monkheang et al. 2011). The flowers are used to treat insomnia and asthma in traditional medicine (Kaur et al. 2006).

Other Uses

Senna siamea is cultivated as windbreaks, shelterbelts, live fence, boundary markers, ornamental in parks and gardens, wayside tree and shade tree for tea, cocoa and coffee plantings. The tree is also used for erosion control, for land reclamation in former tin/aluminium mining sites and in alley cropping systems in agroforestry, largely because of its coppicing ability and high biomass production shade besides also for its nitrogen-fixing capability. In India, it is used as a host for the semiparasitic sandalwood (*Santalum* spp.). In China, it has been cultivated as fuelwood by the Dai people since 400 years ago and as a host plant for lac insects. Its foliage is rich in nitrogen and organic matter and is used as green manure. The foliage can be used as browse or fodder for cattle, sheep and goats but are toxic to poultry and swine. The flower is an important nectar source for bees.

The tree afford a hard, heavy, dense, durable, dark blackish brown and termite-resistant wood that is used in joinery, cabinet making, furniture, inlaying, tool handles, walking sticks, posts, bridges, mine poles and beams and other decorative carvings. All parts of the tree including the bark can be used for tanning.

Comments

Cassod is easily and readily propagated from seeds, although stumps can be used.

Senna timoriensis

Scientific Name

Senna timoriensis (DC.) H. S. Irwin & Barneby

Philippines: Malamalungai

Thai : Khi Lek Daeng, Khi Lek Lueat, Khi Lek Pa

Vietnamese: Muồng Đỏ, Muồng Tía, Khi Pòi

Synonyms

Cassia arayatensis Litv., *Cassia exalta* Blume, *Cassia goensis* Dalzell, *Cassia montana* Naves & Villar, *Cassia montana* auct.non Roth, *Cassia timoriensis* DC., *Cassia timoriensis* DC. basionym, *Senna glauca* Roxb.

Origin/Distribution

The species is native to India, Ceylon, Myanmar, Thailand and through the Malay Peninsula to Northern Australia.

Family

Fabaceae also placed in Caesalpiniaceae

Agroecology

It is a drought-tolerant species naturalized in low elevations from sea level to 200 m. It usually occurs in disturbed sandy sites, sandstone outcrops, stony slopes or in thickets in limestone areas in its native range. It is also cultivated as ornamental and avenue trees.

Common/English Names

Arremene, Golden Bird, Limestone Cassia

Edible Plant Parts and Uses

The bitter young leaves and inflorescence/flowers are edible, cooked as vegetables in Thailand (Pongpangan and Poobrasert 1985). Young leaves and flowers can be used as vegetable by soft boiling and eating with chilli sauce (Monkheang et al. 2011). Both plant parts are sold in local markets in Thailand.

Vernacular Names

Burmese: Taung-Mezali, Taw-Mezalie

Indonesia: Eheng, Hing, Ihing, Nyinging, Ture, Waringinan (*Javanese*), Haringhin (*Sundanese*) Kayu Pelen (*Timor*)

Malaysia: Beresksa, Beksa, Babatai, Bebatiai, Sinteng Hutan (Malay)

Botany

A small, evergreen, perennial tree or shrub usually 2–6 m but may grow to 10 m high, pubescent on vegetative parts, inflorescence, sepals and ovary, otherwise glabrous. Leaves pinnate, 14–20 cm long with a terete 10–15 mm long petiole, acicular stipules and comprising 10–20 pairs of narrowly oblong to narrowly elliptic, 1.5–5.5 cm long by 0.8–1.7 cm wide leaflets, obtuse, apiculate and eglandular (Plates 1 and 2). Inflorescence corymbose panicle, axillary or terminal, bract linear, flowers pedicellate, pentamerous with five unequal sepals, five yellow obovate, clawed petals and ten stamens (seven fertile and three staminodes) with subequal filaments and unequal anthers, ovary superior with 1 style and stigma (Plate 1). Fruit a long narrow, flat, legume, 6–15 cm long by 1–1.5 cm wide, septate with 10–20 shiny brown, suborbicular seeds.

Plate 1 Flowers, pods and leaves

Plate 2 Young tender leafy shoots sold as vegetables in the local markets

Nutritive/Medicinal Properties

Aloe emodin and 2,5-dimethyl-3 α H-pyrano [2,3,4-de]-1-benzopyran-3 α ,8-diol (barakol) were isolated from *Cassia timoriensis* leaves (Gritsanapan et al. 1984).

Cassia timoriensis plant extract was one of several Thai medicinal plants that exhibited good antioxidant activity and could completely inhibit Heinz body formation at the dilution of 1:20 (Palasuwan et al. 2005). Heinz bodies are intracellular precipitates formed by damage to the haemoglobin component molecules in erythrocytes, usually through oxidant damage.

Traditional Medicinal Uses

C. timoriensis is used for scabies and itch and as a vermifuge (Toruan-Purba 1999). The plant is used as medicine for menstrual disorders, tonic, antitumour, blood stasis and cough in Thailand (Palasuwan et al. 2005); the heartwood is used as a traditional medicine by women to stimulate menstrual blood flow (Monkheang et al. 2011).

Other Uses

The plant is commonly grown as ornamental tree in parks and gardens or as shade trees along roads. The wood is used for matchsticks, matchboxes, joinery, cement casks and decorative items.

Comments

The plant is propagated from seeds or stem cuttings.

Slovakian: Sezbánia Vef'kokvetá

Spanish: Baculo, Cresta De Gallo, Gallito, Paloma, Pico De Flamenco, Zapaton Blanco

Sri Lanka: Katurumurunga Kolle (Leaves, Sinhalese), Katurumurunga Mala (Flowers, Sinhalese), Attikkirai (**Tamil**)

Tahitian: Afai, Ofai, Ouai, Oufai

Thailand: Khae Daeng (**Chiang Mai**), Dok Khae Baan, Kae-Ban, Khae, Ton Kae (**Central**)

Tibetan: A Ga Sta

Vietnamese: So Đũa

Origin/Distribution

The species is native to South Asia and Southeast Asia with possibly Indonesia as the centre of diversity. It is closely related to the Australian species, *Sesbania formosa*. The species is now distributed pantropically in Africa, Central America, Florida, Hawaii, Southwest China, Northern Australia, the Caribbean and the Pacific Islands.

Agroecology

The tree is found in open fields, near roadsides or waterways, and dikes between the rice fields from sea level to occasionally 1,200 m altitude in its native range. The plant is cultivated in orchards or as backyard trees in remote areas as an ornamental but has a tendency to naturalize. It is adaptable to tropical conditions in areas with mean annual temperatures of 22–30 °C and mean annual rainfall of 2,000–4,000 mm. It prefers a bimodal rainfall distribution, with rapid growth in the wet, but is drought tolerant withstanding extended dry periods of up to 9 months. It is frost sensitive and is intolerant of protracted period of low cool temperatures. It grows on a wide range of soils including alkaline, saline, acid soils with pH down to 4.5, heavy clays and poorly drained and low fertility soils. It is tolerant to brief periods of flooding.

Edible Plant Parts and Uses

In Asia, young leaves, flowers and young pods are used in curries and soups, lightly fried, steamed or boiled (Burkill 1966; Ochse and Bakhuizen van den Brink 1980; JIRCAS 2010). The young, tender pods are cooked similarly to other green beans. The leaves and young tender pods are used as flavouring items in the cuisine of South India (Yadav et al. 2010). In Sri Lanka, the leaves are sometimes added to ‘sodhi’, a widely eaten, thin coconut gravy. In India, the tender leaves, young green pods and flowers are eaten alone as a vegetable or mixed into curries or salads. The young leaves are chopped and sautéed, perhaps with spices, onion or coconut milk. Seeds are high in protein (33.7 %) and are eaten as famine food in India.

In India, flowers may be dipped in batter and fried in butter. Flowers after removal of the bitter stamens are eaten as vegetables raw or cooked in Southeast Asian countries, namely, Thailand, Laos, Kampuchea, Vietnam, Malaysia, Indonesia and the Ilocos region of the Philippines

and also in Bihar, India. In Thailand young shoots and leaves are blanched and eaten with chilli paste ‘*nam prik kapi*’ or ‘*nam prik plaa raa*’ (JIRCAS 2010). Young flowers are used as an ingredient in sour curry soups such as ‘*kaeng som*’. The flowers are also consumed raw. They are also fried with pork or shrimps or mixed with flour and fried. In the Philippines, unopened white flowers are a common vegetable, steamed or cooked in soups and stews after removal of the stamen and calyx (Stuart 2012). In Vietnam the flowers are used in soups or stir-fry with meat (Tanaka and Nguyen 2007). In Peninsular Malaysia, the leaves are cooked in coconut milk (lemak) or curry (Saidin 2000), and the flowers are commonly used raw in ‘ulam’ (Mackeen et al. 1997) or cooked as vegetables as are the young pods (Saidin 2000). In Sarawak, one popular dish is ‘*duan turi*’ cooked in coconut gravy with shrimp paste, dried pounded shrimps, pumpkin and chillies (Voon et al. 1988). In Indonesia young leaves and pods eaten as sepan (steamed vegetables) and the flowers are used for making sayor or lalab. ‘Petjel’ (sauce) can be made of the flowers by adding ‘sambal kacang’ (Ochse and Bakhuizen van den Brink 1980).

Botany

A small, open-branched, unarmed, perennial tree 5–9 m tall with drooping branches (Plates 1 and 2) and 30 cm trunk with heavily nodulated roots. Leaves glaucous, deep green, pinnately compound to 30 cm long with 20–40 pairs of opposite to alternate leaflets (Plates 1, 2, 3 and 4). Leaflet oblong, to elliptical, obtuse apex, about 2–3 cm long. Inflorescences arise from leaf axils in lax racemes of 2–4 flowers, bracts lanceolate, deciduous, 3–6 mm long. Flowers white or deep pink to red, quite large, 7–9 cm long, corolla with standard and wings, staminal tube and glabrous ovary and style (Plates 1, 2, 3, 4, 5 and 6). Pods pendent, slender, long, 30–55 cm, cylindrical, green, indehiscent containing 15–50 seeds. Seed sub-reniform, 6.5 mm × 5 mm × 3 mm, dark brown.

Nutritive/Medicinal Properties

Leaf Nutrients and Phytochemicals

The leaves and flowers of agathi (*Sesbania grandiflora*) were found to be rich in minerals

and vitamins. The leaves were reported to contain per 100 g edible portion, 8.4 g protein, 11.8 g carbohydrate, 3.1 g fat, 2.2 g fibre,

Plate 6 Mass of white flowers sold in local markets as vegetables

5,400 µg carotene, 169 mg vitamin C, 0.21 mg vitamin B1, 0.09 mg vitamin B2, 1.2 mg niacin, 3.1 g minerals, 1,130 mg Ca, 80 mg P and 3.9 mg Fe (Devi et al. 2007). Duke (1983) reported that per 100 g ZMB (zero-moisture basis), the leaves contained 321 cal, 36.3 g protein, 7.5 g fat, 47.1 g carbohydrate, 9.2 g fibre, 9.2 g ash, 1,684 mg Ca, 258 mg P, 21 mg Na, 2,005 mg K, 25,679 µg β-carotene equivalent, 1.00 mg thiamine, 1.04 mg riboflavin, 9.17 mg niacin and 242 mg ascorbic acid. The flowers contain per 100 g ZMB, 345 cal, 14.5 g protein, 3.6 g fat, 77.3 g carbohydrate, 10.9 g fibre, 4.5 g ash, 145 mg Ca, 290 mg P, 5.4 mg Fe, 291 mg Na, 1,400 mg K, 636 µg β-carotene equivalent, 0.91 mg thiamine, 0.72 mg riboflavin, 14.54 mg niacin and 473 mg ascorbic acid (Duke 1983). Voon et al., (1988) reported the leaves to contain per 100 g edible portion energy 85 kcal, moisture 78.2 %, protein 6 g, fat 0.9 g, carbohydrate 10.9 g, fibre 2.1 g, ash 2 g, P 2 mg, K, 308 mg, Ca 96 mg, Mg 65 mg, Fe 164 µg, Mn 33 µg, Cu 33 µg, Zn 6.6 mg and vitamin C 15.5 mg.

Physicochemical studies of the leaves revealed loss on drying (0.6 %), total ash (10.75 %), acid-insoluble ash (0.045 %), alcohol-soluble extractive (21.7 %) and water-soluble extractive (30.72 %) (Yadav et al. 2010). The leaves were reported to contain alkaloids, saponins, phenols and proteins.

Flower Phytochemicals

The flowers were reported to contain ZMB per 100 g, 345 cal, 14.5 g protein, 3.6 g fat, 77.3 g carbohydrate, 10.9 g fibre, 4.5 g ash, 145 mg Ca, 290 mg P, 5.4 mg Fe, 291 mg Na, 1,400 mg K, 636 µg β-carotene equivalent, 0.91 mg thiamine, 0.72 mg riboflavin, 14.54 mg niacin and 473 mg ascorbic acid (Duke 1983).

Raj and Nagarajan (1984) isolated kaempferol-3-rutinosides from the flowers. Kalyanagurunathan et al. (1985) isolated three active compounds: methyl ester of oleanolic acid, nonacosan-6-one and flavonol glycosides type of molecules, kaempferol-3-rutinosides from the flowers. The flowers were found to have various chemical compounds that could be grouped as flavonoid, anthraquinone, and glycoside (Krasaekoopt and Kongkarnchanatip 2005). Red agati petal (rose-pink to red) of 3 cm length was found to have the highest total anthocyanin content (455 µg/g FW) while hypocotyl of 7-day-old, light-grown Red Agati seedlings also had high anthocyanin content (290 µg/g FW) (Bodhipadma et al. 2006). It was concluded that the hypocotyl of light-grown Red Agati seedlings would be an attractive alternative source of anthocyanins to the petal as the seedlings can be raised and be made available throughout the year.

Yang et al. (2008) found the edible red and white flowers to contain 10.6 %, 10.6 % DM, and 20.4, 22.4 mg/100 g FW of total flavonoids, respectively. The red flower contained (per 100 g FW) 10.1 mg quercetin and 10.3 mg kaempferol while the white flowers contained only 22.4 mg kaempferol and no quercetin. It was found that 70 % alcoholic extract of flowers of *Sesbania grandiflora* had 64.0 mg/g of total phenol equivalent to catechol and 28.80 mg/g of flavonoid content equivalent to quercetin (Shanmukha et al. 2012). The methanol flower extract was found to contain abundant flavonoids, and tannins, alkaloids and anthraquinone glycosides, triterpenes, gums and mucilage (Arthanari et al. 2012). The total polyphenolic content in the acetone flower extract was found to be 49.1 µg/mg and the flavonoid content was 12.86 µg/mg (Munde-Wagh et al. 2012).

Seed Phytochemicals

Seeds (ZMB) were reported to contain 36.5 % CP, 7.4 % fat, 51.6 % total carbohydrate and 4.5 % ash (Duke 1983). The seed oil contains 12.3 % palmitic, 5.2 % stearic, 26.2 % oleic and 53.4 % linoleic acids. The seed testa, which constitutes 20 % of the seed, contains 5.2 % moisture, 1.3 % ash, 0.8 % fat, 2.7 % crude fibre, 0.1 % free reducing sugars, 1.4 % sucrose, 2.8 % nitrogen, 6.3 % pentosans and 65.4 % carbohydrates.

The seed was found to have a galactomannan, with a D-galactose-D-mannose ratio of 1:2 (Srivastava et al. 1968). Methylation of the polysaccharide, followed by hydrolysis, afforded 2,3,4,6-tetra-O-methyl-D-galactose, 2,3,6-tri-O-methyl-D-mannose and 2,3-di-O-methyl-D-mannose in equimolecular proportions. Periodate oxidation of the polysaccharide, followed by reduction and hydrolysis, gave glycerol (1 mol) and erythritol (1.8 mol). The seeds were found to contain kaempferol 3,7-diglucoside, (+)-leucocyanidin and cyanidin 3-glucoside (Andal and Sulochana 1986). The seeds were reported to contain alkaloids, a cyanoglucoside and canavanine (Wenas 1989).

The seed oil of *S. grandiflora* was found to contain (mg/100 g) 258.21 mg total tocopherol, 47.04 mg α -tocopherol, 2.09 mg β -tocopherol, 201.06 γ -tocopherol and 8.02 mg δ -tocopherol, and 74.06 % β -sitosterol, 9.21 % campesterol, 2.06 % Δ^7 -avenasterol, 3.02 % stigmasterol, 7.65 % Δ^5 -avenasterol and 4 % unidentified sterol (Shareef et al. 2012).

Root Phytochemicals

The roots were found to contain indole acetic acid (IAA), gibberellic acid-like substances (GAs), cytokinin-like substances (CKs) and abscisic acid-like substances (ABA) (Bhowmick and Basu 1984). A steroid was isolated from the roots (Mandey et al. 2003). Three isoflavonoids, isovestitol, medicarpin and sativan, along with another known compound, betulinic acid, were isolated from the root (Hasan et al. 2012). A new biaryl natural product, 1,1'-binaphthalene-2,2'-diol,

and two known isoflavonoids, isovestitol and sativan, were isolated from the roots (Noviany et al. 2012).

Gum exudates from *S. grandiflora* were found to compose of strongly dextrorotatory, acidic arabinogalactans (Anderson and Wang 1990).

Antioxidant Activity

Studies by Ramesh and Begum (2008) suggested that supplementation with aqueous suspension of *S. grandiflora* reversed the cigarette smoke-induced oxidative damage in rats through its antioxidant potential. Cigarette smoke-enhanced levels of protein carbonyl and activities of cytochrome P450, NADPH oxidase and xanthine oxidase and cigarette smoked-induced decreases in levels of total thiol, protein thiol, non-protein thiol, nucleic acids and tissue protein in the lung, liver, kidney and heart of cigarette smoke-exposed rats were altered and normalized by the extract. The results provided further support for the traditional use of *S. grandiflora* in the treatment of smoke-related diseases. The methanol flower extract of *S. grandiflora* exhibited maximum radical scavenging activity in vitro on nitric oxide, superoxide and hydroxyl radical, and these values were significantly higher over positive standards butylated hydroxyanisole and butylated hydroxytoluene (Loganayaki et al. 2012).

Antidiabetic Activity

Two alpha-glucosidase inhibitors named SGF60 and SGF90 were isolated from the *Sesbania grandiflora* flowers (Boonmee et al. 2007). SGF90 matched a beta-glucosidase from *Arabidopsis thaliana*. SGF60 was similar to p27SJ, a protein from *Hypericum perforatum* and found to suppress HIV-1 gene expression.

Anticancer Activity

Studies showed that a protein fraction, SF2 (Sesbania Fraction 2), isolated from *S. grandiflora*

flowers inhibited cell proliferation and induced apoptosis as evidenced by DNA fragmentation and externalization of phosphatidyl serine in Dalton's lymphoma ascites (DLA) and colon cancer cells (SW-480) (Laladhas et al. 2010). In-vivo studies using ascites and solid tumour models strongly confirmed in-vitro findings as SF2 administration increased the life span and decreased the tumour volume in mice bearing tumour. In-vivo toxicological evaluation revealed the pharmacological safety of SF2, suggesting that it may serve as a potential anti-cancer drug candidate. Administration of *Sesbania grandiflora* ethanol leaf and flower extracts exerted significant decrease in tumour volume, viable cell count and tumour weight and elevated the life span of Ehrlich ascites carcinoma-bearing mice (Sreelatha et al. 2011). Haematological profile such as RBC, haemoglobin and lymphocyte count reverted to normal level in the extract-treated mice. The extracts significantly decreased the levels of lipid peroxidation and significantly increased the levels of GSH, SOD and CAT. The flower extract of *S. grandiflora* inhibited proliferation of human leukaemic cells by inducing autophagy and apoptosis (Roy et al. 2012).

Seven 'ulam' (raw traditional vegetables) extracts, namely, *Anacardium occidentale*, *Garcinia atroviridis*, *Sesbania grandiflora*, *Barringtonia racemosa*, *Polygonum minus*, *Kaempferia galanga* and *Etilingera elatior* displayed cytotoxic activity against the HeLa (human cervical carcinoma) cell line with CD_{50} values in the range of 10–30 $\mu\text{g/ml}$ (Mackeen et al. 1997). The 'ulam' vegetables demonstrated potential as 'functional food' in view of the significant therapeutic and nutritive benefits. The methanol flower extract of *S. grandiflora* exhibited potential cytotoxic activity against human cervical cancer cell line HeLa (IC_{50} value of 0.13 mg/ml) (Loganayaki et al. 2012).

Antibacterial Activity

Aqueous flower extract exhibited antibacterial activity against *Bacillus cereus*, *Escherichia*

coli and *Staphylococcus aureus* (Krasaekoopt and Kongkarnchanatip 2005). The methanol flower extract of *Sesbania grandiflora* in combination with oxytetracycline exhibited synergistic antibacterial activity against 12 different Gram-positive and Gram-negative bacteria, namely, *Shigella sonnei*, *Escherichia coli*, *Shigella boydii*, *Rhodococcus terrae*, *Micrococcus flavum*, *Flavobacterium devorans*, *Brevibacterium leuteum*, *Bacillus licheniformis*, *Salmonella typhi*, *Klebsiella pneumonia*, *Micrococcus luteus* and *Shigella flexneri* (Kumar et al. 2008). The MIC values ranged from 62.5 to 1,000 $\mu\text{g/ml}$. The highest synergism effect was attained against *Shigella boydii*. The flower extracts showed good activity against *Pseudomonas aeruginosa*, *Staphylococcus aureus* and *Escherichia coli* (Munde-Wagh et al. 2012). Polyphenolic extracts (PE) of edible flower of *Sesbania grandiflora* exhibited in-vitro inhibitory effect against *Staphylococcus aureus*, *Shigella flexneri*, *Salmonella typhi*, *Escherichia coli* and *Vibrio cholerae*. The Gram-positive organism *S. aureus* was the most sensitive to the extract with minimum inhibitory concentration (MIC) of 0.013 mg/ml , where *V. cholerae* was not sensitive with a high MIC of 0.25 mg/ml (China et al. 2012).

The butanol fraction of the crude ethanol extract of the stem bark was found to possess the most pronounced antibacterial activity against Gram-negative bacteria (Anantaworasakul et al. 2011). Isovestitol (1), medicarpin (2), sativan (3) and betulinic acid (4) isolated from the roots exhibited antituberculosis activity against *Mycobacterium tuberculosis* H37Rv, with MIC values of 50 $\mu\text{g/ml}$ for compounds 1–3 and 100 $\mu\text{g/ml}$ for compound 4, whereas the methanol root extract exhibited antituberculosis activity of 625 $\mu\text{g/ml}$.

Das et al. (2013) developed a simple, rapid and effective method for the green synthesis of silver nanoparticles (AgNPs) using leaf extract of *Sesbania grandiflora* and demonstrated their in-vitro potent antibacterial activity against multidrug-resistant (MDR) bacteria such as *Salmonella enterica* and *Staphylococcus aureus*.

Antiviral Activity

Of all the flower extracts (petroleum ether, chloroform, ethyl acetate, ethanol, methanol and water) of *S. grandiflora*, the methanol flower extract exhibited the strongest antiviral activity against the following viruses grown in different cell lines like He1, HeLa, Crandell Reus feline kidney and Vero cell (Arthanari et al. 2012). *S. grandiflora* flower extracts were found not to be toxic with MIC at 20 µg/ml in Vero cells and 100 µg/ml in the other cell lines. The methanol extract exhibited potent activity against herpes simplex 1 and 2, respiratory syncytical, parainfluenza, reo-1, sindbis, coxsackie and Punta Toro viruses with EC_{50} =20 and 45 µg/ml and moderate activity against vaccinia, vesicular stomatitis, feline corona, feline herpes and viruses (EC_{50} =100 µg/ml).

Probiotics Stimulating Activity

Polyphenolic extracts of edible flower of *Sesbania grandiflora* exhibited growth-promoting effect on the common probiotic bacterium *Lactobacillus acidophilus* (China et al. 2012). *S. grandiflora* extract induced a significant biomass increase of *L. acidophilus* grown in liquid culture media.

Antiurolithiatic Activity

The leaf juice of *S. grandiflora* showed significant antiurolithiatic activity against calcium oxalate-type stones as evaluated by a calculi-producing diet model in rats (Doddola et al. 2008). It also exhibited antioxidant properties in scavenging of nitric oxide and 2-diphenyl-2-picrylhydrazyl-free (DPPH) radicals. The leaf juice of *S. grandiflora* was safe orally and exhibited no gross behavioural changes except for an increase in urination.

Antihyperlipidaemic Activity

Administration of a dose of 200 µg/kg (p.o.) aqueous leaf extract of *S. grandiflora* to the

triton-induced hyperlipidaemic rats significantly decreased levels of serum cholesterol, phospholipid, triglyceride, LDL and VLDL and significantly increased serum HDL level (Saravanakumar et al. 2010).

Anticonvulsant and Anxiolytic Activities

Studies showed that the benzene:ethyl acetate fraction (BE) of a petroleum ether leaf extract of *S. grandiflora* significantly delayed the onset of convulsions in pentylenetetrazol- and strychnine-induced seizures in mice and reduced the duration of tonic hindleg extension in the maximum electroconvulsive shock (MES)-induced seizures in mice (Kasture et al. 2002). The BE fraction was found to contain a triterpene as a major component. BE also suppressed electrically induced kindled seizures in mice and lithium-pilocarpine-induced status epilepticus in rats. It prolonged the duration of sleep induced by pentobarbital and antagonized the effect of D-amphetamine. Mice treated with BE preferred to remain in the open arm of the elevated plus maze indicating anxiolytic activity. The BE raised the brain contents of gamma-aminobutyric acid and serotonin. Thus, the triterpene containing fraction of *S. grandiflora* exhibited a wide spectrum of anticonvulsant profile and anxiolytic activity.

Hepatoprotective and Nephroprotective Activities

Oral administration of an ethanol extract of *S. grandiflora* leaves (200 mg/kg/day) for 15 days produced significant hepatoprotection against erythromycin estolate (800 mg/kg/day)-induced hepatotoxicity in rats (Pari and Uma 2003). The increased level of serum enzymes (aspartate transaminase, alanine transaminase, alkaline phosphatase), bilirubin, cholesterol, triglycerides, phospholipids, free fatty acids, plasma thiobarbituric acid-reactive substances and hydroperoxides observed in rats treated with erythromycin estolate was significantly decreased

in rats treated concomitantly with sesbania extract and erythromycin estolate. The sesbania extract also restored the depressed levels of antioxidants to near normal. The results of the study reveal that sesbania could afford a significant protective effect against erythromycin estolate-induced hepatotoxicity.

The ethanol extract at doses of 250 and 500 mg/kg, p.o. and aqueous extract at a dose of 500 mg/kg, p.o. of *Sesbania grandiflora* flowers exhibited significant hepatoprotective effect against carbon tetrachloride-induced hepatotoxicity in the liver of Swiss Albino rats (Kale et al. 2012). Both extracts were effective in bringing about functional improvement of hepatocytes.

The petroleum ether extract of *Sesbania grandiflora* fruit exhibited significant dose-dependent (100 mg, 200 mg/kg p.o.) protective effect against thioacetamide- and ranitidine-induced hepatotoxicity in Wistar albino rats (Ramakrishna et al. 2012). The fruit extract completely prevented the toxic effects of thioacetamide and ranitidine on biochemical parameters like serum glutamic oxaloacetic transaminase, serum glutamic pyruvic transaminase, alkaline phosphatase, total bilirubin, total cholesterol, total protein and histopathological alterations.

The results of studies by Ramesh et al. (2010) indicated that *S. grandiflora* aqueous leaf suspension significantly decreased the elevated hepatic, renal and lipid peroxidation markers and ameliorated the diminished antioxidant levels while restoring the hepatic and renal architecture in cigarette smoke-exposed rats. They concluded that *S. grandiflora* leaves ameliorated cigarette smoke-induced oxidative damage in liver and kidney of rats.

Studies by Kumaravel et al. (2011) found that *Sesbania grandiflora* protected kidney against alcohol and polyunsaturated fatty acid-induced oxidative stress. The elevated levels of thiobarbituric acid-reactive substances (TBARS) and lipid hydroperoxides induced by oxidative stress were reduced by treatment with the extract. The decreased levels of both enzymatic and non-enzymatic antioxidants were restored on treatment with *S. grandiflora*. The authors attributed this nephroprotective effect to

the phenolic compounds and anthocyanins present in the plant.

Cardioprotective and Pulmoprotective Activities

Treatment of adult male Wistar-Kyoto rats (exposed to cigarette smoke for a period of 90 days) with *S. grandiflora* aqueous suspension (SGAS, 1,000 mg/kg bw per day orally) for a period of 3 weeks restored the antioxidant status and retained the levels of micronutrients (Ramesh et al. 2008). In contrast rats exposed to cigarette smoke had significantly increased lactate dehydrogenase activity in serum and cardiac lipid peroxidation product level, and the levels of cardiac superoxide dismutase, catalase, glutathione peroxidase, glutathione reductase, glutathione-S-transferase and glucose-6-phosphate dehydrogenase and levels of reduced glutathione, vitamin C and vitamin E were significantly decreased. Besides, copper level was elevated, whereas zinc, manganese and selenium levels were significantly diminished in the heart of rats exposed to cigarette smoke. The results suggested that *S. grandiflora* protected the heart from the oxidative damage through its antioxidant potential. Similarly, they found that *S. grandiflora* protected the lungs of cigarette smoked-exposed rats against chronic oxidative stress and damage through its antioxidative potential (Ramesh et al. 2007).

Analgesic and CNS Depressant Activities

The leaf extract of *S. grandiflora* was found to have analgesic and CNS depressant activity (Sutradhar and Choudhury 2012). In the acetic writhing test, a dose-dependent reduction in the number of abdominal constriction was observed in animals treated with different concentration of methanol leaf extract of *S. grandiflora*. At the dose of 250 and 500 mg/kg, 68.13 and 85.56 % inhibition of writhing response was observed, respectively. In the tail-flick method, the duration

of heat tolerance was dependent on the dose of the extract, and the onset of action was very rapid, faster than diclofenac Na. The tail-flick test and acetic acid writhing test were used to elucidate central and peripheral antinociceptive effect, which were both central and peripheral, and the results indicated the extract to have analgesic activity. In the open field and whole cross tests, both 250 and 500 mg/kg leaf extract of *S. grandiflora* gave rapid onset of action and produced rapid sleeping, indicating the extracts had neurological activity, namely, CNS depressant activity.

Antiinflammatory and Analgesic Activities

S. grandiflora flower extract exhibited antiinflammatory activity in the rat paw oedema test (Tamboli 1996), and the flower extracts also demonstrated analgesic (tail-flick test) and antipyretic activity (Brewer's yeast-induced pyrexia assay) (Tamboli 2000).

The methanol flower extracts of *S. grandiflora* showed significant inhibitory activity against inflammation in the carrageenan and cotton pellet-induced animal models and analgesic activity in hot-plate pain model (Loganayaki et al. 2012). The inhibitory values were comparable with positive standards.

Increased paw oedema of the injected paw measured on 1st to 12th hours, a feature of carrageenan-induced inflammation in Wistar rats, was significantly reduced after prophylactic oral administration of petroleum ether, chloroform and methanol extracts of bark of *Sesbania grandiflora* (300 mg/kg bw) and *Sesbania sesban* (300 mg/kg bw) (Patil et al. 2010). Increased swelling of the non-injected paw (secondary paw) measured on days 14 and 21; injected paw swelling (primary paw) measured on days 3, 14 and 21; splenomegaly; thymic involutions; and loss in body weight, all features of adjuvant-induced arthritis, were effectively reduced after prophylactic administration of extracts of bark of *Sesbania grandiflora* and *Sesbania sesban*. Albino rats treated with the ethanol stem bark

extract of *S. grandiflora* showed significant increase in the tail-flick latency compared to control, and the ethanol extract suppressed carrageenan-induced oedema in rats when compared to control (Swetha et al. 2012).

Antiulcerogenic Activity

Animal studies showed that the ethanol bark extract of *S. grandiflora* had antiulcer potential (Serti et al. 2001). The extract significantly prevented stress and nonsteroidal antiinflammatory drug-induced gastric lesions in rats. At a dose of 36.75 mg/kg (ED₅₀) p.o., the extract did not modify the volume, pH and hydrochloric acid contents of gastric secretion. The ethanol leaf extract of *S. grandiflora* at a dose of 400 mg/kg produced a significant reduction in the ulcer index of rats with gastric injury induced by aspirin, ethanol and indomethacin (Bhalke et al. 2010). The extract significantly suppressed gastric mucosal damaged induced by aspirin, ethanol and indomethacin. In pylorus-ligated Shay rats, the extract significantly reduced basal gastric secretion. The antiulcer effect was further confirmed histologically.

Wound Healing Activity

Both concentrations (2 and 4 % w/w ointment) of ethanol flower extract of *S. grandiflora* showed significant wound healing (wound closure) and tensile strength increase in both excision and incision wound models tested in Wistar rats when compared with control group (Sheikh et al. 2011). The effects were comparable to the standard nitrofurazone ointment (0.2 %w/w).

Anthelmintic Activity

S. grandiflora seed oil exhibited high anthelmintic activity in both paralysis and time of death of test earthworm, *Pheretima posthuma* (Jalalpure et al. 2010).

Adverse Haemolytic Activity

Aqueous leaf extract of *Sesbania grandiflora* produced haemolysis of human and sheep erythrocytes even at very low concentrations (Kumar et al. 1982). Haemolysis was greater when the pH was acidic. The liberation of phospholipids and sterols into the supernatant as a result of haemolysis indicated possible damage to the erythrocyte membrane. The aqueous flower extracts *S. grandiflora* produced haemolysis of human and sheep erythrocytes even at low concentration (Kalyanagurunathan et al. 1985). The active principle responsible for the haemolytic effect was characterized as the methyl ester of oleanolic acid.

Traditional Medicinal Uses

Various parts of the tree have been used in folkloric medicine in south and Southeast Asian countries (Burkill 1966; CSIR 1972; Stuart 2012; Kirtikar 1993; Tanaka and Nguyen 2007; Wagh et al. 2009). According to Duke and Wain (1981), *S. grandiflora* is reported to be aperient, diuretic, emetic, emmenagogue, febrifuge, laxative, and tonic and used as a folk remedy for bruises, catarrh, dysentery, eyes, fevers, headaches, smallpox, sores, sore throat and stomatitis. Bark, roots, leaves, gum and flowers are considered medicinal.

Sesbania grandiflora is widely used in Ayurveda for the treatment of diseases and for processing of various formulations in Rasashastra (Yadav et al. 2010). It is used for its astringent, antihistaminic, anxiolytic, anticonvulsive and febrifugal properties. Ayurvedics, believing the fruits to be alexeteric, laxative and intellectually stimulating, prescribe them for anaemia, bronchitis, fever, pain, thirst, ozena and quartan fever (Ramakrishna et al. 2012). Yuani considers the tonic levels useful in biliousness, fever and nyctopia. In local folk medicine, it is applied as aperients, diuretic, emetic, emmenagogue, febrifuge, laxative and tonic (Wagh et al. 2009). In the indigenous system of medicine in India, *Sesbania grandiflora* is claimed to be useful for various ailments, and one such use is for the treatment of

renal calculi (Doddola et al. 2008). One traditional use of *S. grandiflora* is in the treatment of smoke-related diseases (Ramesh and Begum 2008). *Sesbania grandiflora* is widely used in Indian folk medicine for the treatment of liver disorders (Pari and Uma 2003). Various parts of this plant are used in Indian traditional medicine for the treatment of a broad spectrum of illness including leprosy, gout, rheumatism and liver disorders. The bark is reported to cure diarrhoea, dysentery, paludism, snakebite, malaria, smallpox, eruptive fever, scabies, ulcer and stomach disorders in children; in high doses it causes vomiting and mild diarrhoea (Kirtikar 1993). Indians apply the roots in rheumatism and the juice of the leaves and flowers for headache and nasal catarrh (Saravanakumar et al. 2010). The Yanadi tribe in the Chittoor District of Andhra Pradesh used the flowers for cataract, conjunctivitis, kidney and bladder stones and alopecia (Vedavathy et al. 1997).

Burkill (1966) has reported on its medicinal uses in Malaysia, Java and also in India. The bark is considered tonic and is bitter the bark extract acts as aperient and larger doses are emetic, and small doses are prescribed for dysentery and other bowel complaints. Bark extract is also prescribed for ulceration of the tongue and alimentary tract. In Java, it is used for thrush and infantile disorders of the stomach. Dried powdered bark is used as cosmetic in Java. An infusion of the leaves is used as aperients, leaf juice prescribed for dim vision and the leaves boiled in vinegar or arrack applied to sprains. In Amboina, flower juice is squeezed into the eye to correct dim vision. The bark is used in infusions for smallpox. An herbal preparation of dried powdered leaves mixed with leaves of *Citrus* lime, *Parkia* seeds and wood ash moistened with vinegar is rubbed on the abdomen for a fortnight after confinement. Consumption of large quantities of leaves can cause diarrhoea. Saidin (2000) reported that the leaf juice is taken to reduce nose inflammation and cough and to expel mucus in Malaysia. The cortex has been used to treat dysentery, indigestion and diarrhoea in Vietnam (Tanaka and Nguyen 2007). In the Philippines, the pounded bark is employed for haemoptysis;

the powdered bark is also recommended for ulcers of the mouth and alimentary canal (Stuart 2012). Cambodians consider the flowers emollient and laxative and the bark for diarrhoea, dysentery and paludism.

Other Uses

According to NAS (1979, 1980), *S. grandiflora* is an important source of firewood, forage, pulp and paper, food, medicine, green manure and shade tree and has potential for reforestation eroded and grassy wastelands throughout the tropics. The tree combines well with agriculture (agroforestry) in areas where trees are not normally grown and becomes an important fuel-wood source. The small tree is often grown as a light shade tree for companion plants such as turmeric, galangal and ginger and as a live support tree for climbing plants such as black pepper and betel vine. It is also grown as an ornamental in home gardens, as living fences and as windbreak. The tree is also grown around fields, eroded hill slopes and wastelands as it is planted to ameliorate soils and improve their fertility, especially their nitrogen content. In South Asia and Southeast Asia, its foliage is valued as fodder for cattle and goats. The fast-growing seedlings and the tree foliage make excellent green manure. In Java, the tree is extensively used as a pulp source. The trunks may be used for light construction like bamboos and have been used as poles for temporary shelters and sheds, but they may not last very long due to rots and insect infestation. The bark yields a tanning agent. The gum exuding from a cut in the bark has properties of gum Arabic and is used by fisher-folks for toughening nets and lines. An aqueous extract of bark is said to be toxic to cockroaches. The inner fibrous bark and the white, soft wood can be used for cork.

Comments

The toxic compound, sesbanimide, was detected in seeds of *Sesbania drummondii*, *S. punicea* and *S. vesicaria* but not detected in seeds of *S. grandiflora*,

S. emerus, *S. exaltata*, *S. sesban*, *S. speciosa* and *S. sonorae* (Powell et al. 1990) and has been erroneously reported in literature to be present in the seeds of *S. grandiflora*.

Sesbania javanica

Scientific Name

Sesbania javanica Miq.

Laotian: Sanô; Sanô:Sanô, Kho:Ng Kh'wa:Y

Russian: Sesbanya Yavanskaya

Thai: Sano Kin Dok, Phak Hong Haeng, Si Pree
Laa, Sano Hin

Vietnamese: Dien Dien Phai, Dien Thanh Hat
Thron

Synonyms

Aeschynomene paludosa Roxb., *Sesbania aculeata* (Willd.) Pers. var. *paludosa* (Roxb.) Baker, *Sesbania aculeata* var. *paludosa* Baker, *Sesbania cochinchensis* Kurz, *Sesbania cochinchinensis* (Lour.) DC., *Sesbania paludosa* (Roxb.) Prain, *Sesbania paludosa* (Roxb.) King, *Sesbania roxburghii* Merr.

Origin/Distribution

The species is found in India, Bangladesh, Sri Lanka, Indonesia (Java), Malaysia, Papua New Guinea, Philippines, Cambodia, Laos, Myanmar, Thailand, Vietnam, South China and Taiwan.

Family

Fabaceae also in Papilionaceae

Agroecology

It thrives in subtropical to tropical regions, occurring naturally in wet marshy lands or banks of waterways, ditches and rice fields.

Common/English Names

Marsh Sesbania, Yellow Wisteria

Edible Plant Parts and Uses

Vernacular Names

Chinese: Yan Sheng Tian Jing, Zhao Wa Tian Jing

French: Sesbanie De Java

German: Gelbe Wisterie

Hawaiian: Kathsola

India: Kathsola (Hindi, Sanskrit)

Khmer: Snaô(r)

The young leaves and flowers are used as a green vegetable in Thailand and Vietnam boiled in soup and curries, fried with meat or added to steamboat dishes. Seed sprouts are used as mung bean sprouts (Tanaka and Nguyen 2007; Loedsaksaesakul 2007; Wetwitayaklung et al. 2008; JIRCAS 2010). In Thailand, the young shoots are cooked and eaten with 'nam phrik'.

The flowers are eaten either raw in salad, blanched, fried with egg or fermented and are served with ‘nam phrik kapi’. As the flowers contain a carotenoid substance, they are used to impart a yellow colour to various desserts such as ‘kanom bua loi’, which are coloured balls of sticky rice flour cooked in sweetened coconut milk.

Botany

Shrub 1–4 m high, erect, with cylindrical green or purplish much-branched stem. Leaves compound paripinnate with 10–30 pairs of narrow linear leaflets arranged subalternately or opposite along the rachis. Leaflets 20–25 mm long and 2–44 mm wide, stipules 5–6 mm long. Inflorescences racemose, pendant 5–12 flowered, pendant from leaf axils, 5–12 cm long with 5–12 moderately large yellow flowers 2.5 cm wide with 5 fused petals, 5 sepals and many stamens (Plate 1). Pods brown or purplish 20 cm long and 0.5 cm wide, linear, straight pendant, with many globular (3 mm diameter) brown seeds.

Nutritive/Medicinal Properties

Nutrient composition (g/100 DM) of the flower had been reported by Kijparkorn et al. (2010) as crude protein 23.46 g, ether extract 2.27 g, crude fibre 15.05 g, ash 8.47 g, Ca 0.83 g P 1.02 g and energy 2790 kcal/kg. Amino acids composition of Sano based on dry matter basis was 1.11, 0.34, 0.63, 0.88, 0.96, 0.95, 1.46, 1.17, 0.61, 0.92, 0.92, 1.19, 1.37, 4.08 and 2.08 for lysine, methionine, methionine plus cystine, threonine, arginine, isoleucine, leucine, valine, histidine, phenylalanine, glycine, serine, alanine, aspartic acid and glutamic acid, respectively. Pigment composition of sano flowers were reported as total carotenoids 307 mg/kg, *b*-carotene 63.19 %, *b*-cryptoxanthin 16.73 %, *cis*-lutein 5.45 %, *trans*-lutein 9.695, epoxide-lutein 3.74 % and *trans*-zeaxanthine 1.21 % (Kijparkorn et al. 2010).

β -sitosterol, prunetin, genistein, 4-hydroxycinnamic acid and sistosterol-3-*O*- β -D-glucopyranoside were isolated from the flowers and

Plate 1 Flowers of Marsh Sesbania

leaves of *S. javanica* (Loedsaksaesakul 2007). Prunetin, genistein and 4-hydroxycinnamic acid exhibited antioxidant activity using DPPH assay.

The flower and crude extract was found to have low total polyphenol contents (0.31 g/100 g dried flowers or 2.39 g/100 g crude extract), and the antioxidant activity in terms of TEAC (trolox equivalent antioxidant capacity) is low (TEAC=0.2, IC₅₀=500.35 μ g) when compared to trolox (TEAC=1) (Wetwitayaklung et al. 2008). In Thailand, the flowers are used for stomachache and burned tree ash as diuretic.

Flowers were reported to have antimutagenic activity (Tangvarasittichai et al. 2005). Dimethyl sulfoxide extract of the flower showed a strong inhibitory effect against aflatoxin B1 (AFB1) and benzo(a)pyrene [B(a)P], mutagens. The flavonol glycoside, quercetin 3-2G-rhamnosylrutinoside, was confirmed by its physicochemical properties as a major constituent of the flower. Quercetin 3-2G-rhamnosylrutinoside (207 μ g/plate) also showed a strong inhibitory effect against AFB1 and B(a)P with more than 70 % inhibition rate.

Other Uses

Its soft stems are used to make cork. The plant is used also for animal fodder and as green manure for soil improvement.

Studies showed that using dried sano flowers in the diet of layers had a beneficial effect in enhancing egg yolk colour (Kijparkorn et al. (2010).

Moreover the high content of β -carotene with pro-vitamin activity and high protein content make it suitable as poultry feedstuff.

Comments

Studies by Gross (2010) found the names *Sesbania javanica* Miq. and *S. sesban* (L.) Merr. do not apply to species native to Australia and *Sesbania benthamiana* has been misapplied. The name *Sesbania burbidgei* is proposed to account for specimens previously identified as *Sesbania sesban*, and *Sesbania muelleri* is proposed to account for specimens previously assigned as *Sesbania benthamiana*. The name *Sesbania benthamiana* is reapplied to material previously known as *Sesbania javanica*.

Family

Fabaceae

Common/English Names

Chinese Scholar Tree, Japanese Pagoda Tree, Pagoda Tree, Scholar Tree, Umbrella Tree

Vernacular Names

Brazil: Sôfora Do Japão (Portuguese)

Chinese: Huái Hua, Huái Hua Mo, Huái Jiao, Huái Mi, Huái Shu

Czech: Jerlín Japonský

Danish: Pagodetræ

Eastonian: Jaapani Keepuu

French: Arbre Aux Pagodes, Arbre De Miel, Arbre Des Pagodes Du Japon, Sophora Du Japon

German: Japanischer Perlschnurbaum, Japanischer Schnurbaum, Pagodenbaum Sophore

Hungarian: Japánakác

Indonesia: Sari Cina

Italian: Sofora, Sofora Del Giappone

Japanese: Enju

Korean: Hoe-Wha-Na-Moo

Polish: Perełkowiec Japoński, Szupin Chiński, Szupin Japoński

Portuguese: Acácia-Do-Japão

Slovenčina: Sofora Japonská

Spanish: Acacia Del Japón, Arbol De Las Pagodas, Sófora

Swedish: Pagodträd

Turkish: Japon Soforası

Vietnamese: Hoè

Origin/Distribution

The species is indigenous to East Asia—Central and Northern China and Korea. It is now widely cultivated in temperate and subtropical regions of the world and infrequently in the highlands in the tropics, e.g. in Southeast Asia, in Vietnam and Thailand.

Agroecology

A cool climate species, being native to the temperate and subtropical regions of Eastern Asia will withstand warm but not hot temperatures. It is frost tolerant down to -25°C when mature except when young. It will grow in the cooler and drier areas of the highlands in the tropics as it is drought tolerant. The tree is found in wasteland and open country between 300 and 1,000 m altitude in its native range. The tree is well adapted to wide range of soil types including poor soils, but thrives best in well-drained, moderately fertile, sandy loams in full sun.

Edible Plant Parts and Uses

The young tender leaves, shoots and twigs, flowers and seeds are edible cooked (Uphof 1968; Read 1982; Kunkel 1984; Facciola 1990; Hu 2005). Leaves are cooked with rice and consumed (Uphof 1968; Read 1982). Shoots are sun-dried and boiled several times to remove the bitter elements before eating. The twigs are thoroughly boiled in water into which an egg is poached; the liquid is then drunk and the poached egg consumed as a home remedy for stopping haemorrhages (Hu 2005). Flowers and buds are gathered and used as an important ingredient in the traditional Five Flower Tea ('Wu Hua Cha') for the hot summer season in Hong Kong. The leaves can also be made into tea and an edible starch is

obtained from the seed (Facciola 1990). The seed endosperm is cooked with sugar to prepare a dessert that is eaten in Northern China (Hu 2005).

Botany

A small to medium-sized, deciduous perennial tree, up to 5–15(–30) m tall with a short stout bole, rough, greyish-brown, fissured bark and upright, spreading branches and glabrous, terete, pale green, lenticillate twigs and broad round crown (Plates 1 and 2). Leaves are arranged spirally, imparipinnate, 15–25 cm long with caducous stipules; leaflets are subopposite and shortly petiolulate, 13–17, elliptical to ovate-lanceolate (Plates 2 and 5), 1.5–6 cm by 1–2.5 cm, acute to subacute apex, obtuse at the base, margin entire, sparsely pubescent below, bright green turning to yellow in autumn. Flowers are bisexual, papilionaceous, mildly fragrant, small pentamerous, in terminal, 15–35 cm long upright panicles (Plates 3 and 4), bracteoles present, calyx campanulate, 3–4 mm long with 5-teeth, corolla 5 white or greenish-white petals, standard broad and cordate, 12–15 mm long with curled margins (Plate 5), stamens 10 free but filaments joined near the base, ovary superior and pilose. Fruit an indehiscent, terete leguminous pod, 3–12 cm by 7–12 mm, green turning to yellow when mature, constricted between the seeds, stipitate, glabrous, distinctly beaked, 2–5-seeded. Seeds

Plate 2 Ascending slender branches and twigs

Plate 4 Panicle with some opened flowers (Nguyen VT)

Plate 3 Large panicle with flower buds (Nguyen VT)

ellipsoid to ovoid, 8 mm×4–5 mm, slightly compressed, yellowish-brown.

Nutritive/Medicinal Properties

Flower Phytochemicals

Blossoms were found to contain sophorin (A,B, C) (Brauns and Schmidt 1904; Vo 1997) and four to five times as much rutin as does

Plate 5 Pinnate leaves and inflorescence with white flowers (Nguyen VT)

buckwheat, the best domestic source (Couch et al. 1952). Rutin content declined as the bud opened and continued to fall as the seed pod formed. No rutin was found in the seed while traces occurred in the leaves. Sophoroflavonoid, kaempferol-3-rhamnoglucoside, genistein-7-D-cellobioside, sophoricoside, sophorabioside, betulin and sophoradiol were isolated from the flower buds (Kariyone et al. 1956; Takahashi et al. 1960; Ishimasa 1960), flavonoids: quercetin, rutin and isorhamnetin-3-rutinoside, kaempferol-3-rutinoside (Kimura and Yamada 1984); and isorhamnetin-2-(3-methoxy-4-hydroxyphenyl)-3,5,7-trihydroxy-4H-1-benzopyran-4-one were isolated from the flower buds (Ishida et al. 1998). Three new glucuronide saponins, named kaikasaponin I, kaikasaponin II and kaikasaponin III,

were isolated from buds of *Sophora japonica* together with five known glucuronide saponins soyasaponin I, soyasaponin III, azukisaponin I, azukisaponin II and azukisaponin V (Kitagawa et al. 1988). The structures of kaikasaponins I, II and III were elucidated as 3-*O*-[β -D-galactopyranosyl-(1 \rightarrow 2)- β -D-glucuronopyranosyl]sophoradiol, 3-*O*-[α -L-rhamnopyranosyl-(1 \rightarrow 2)- β -D-glucopyranosyl-(1 \rightarrow 2)- β -D-glucuronopyranosyl]sophoradiol and 3-*O*-[α -L-rhamnopyranosyl-(1 \rightarrow 2)- β -D-galactopyranosyl-(1 \rightarrow 2)- β -D-glucuronopyranosyl]sophoradiol, respectively.

Accumulation of rutin started with initiation of the flower buds, reaching a maximum content of 287 mg/g (dry weight) during the earliest stages of flower development (Gevrenova et al. 2007). A further decline in the amount of rutin up to 44 mg/g was found proportionally with the decline of flavonoids throughout and after the flowering period. Rutin was the predominant glycoside and accounted for up to 90 % of flavonoid glycoside mixture in young buds, whereas sophorabioside (64.7 mg/g, calculated as rutin equivalent) and kaempferol 3-rutinoside (46.8 mg/g) dominated at later development stages of the fruits. Balbaa et al. (2009) reported that rutin reached its maximum in the flower buds (23 %). Maximum yield and efficiency of extraction of rutin from *Sophora japonica* flowers was improved by the application of ultrasound to methanol extraction but was dependent on the solvent employed (Paniwnyk et al. 2001). Rutin being a compound with antioxidant activity and aqueous solvents appeared to be unsuitable for ultrasonic extractions due to the formation of free radicals from the insonation of the solvent. The flower buds (Huai Mi) and flowers (Huai Hua) of *S. japonicum* (collectively Flos Sophorae) contained rutin as the main flavonoid and lacked the flavone glycosides that were present in flower buds and flowers of *Sophora flavescens* (Kite et al. 2009).

Fruit/Seed Phytochemicals

Sophorobioside, a glycoside, was isolated from the fruit (Farkas et al. 1968). Flavonoids isolated

from the fruit included rutin, quercetin, genistein, kaempferol, sophorobioside, sophoricoside and sophoroflavonolloside (Tulaganov and Gaibnazarava 2001). Two kaempferol triglycosides: kaempferol 3-*O*- β -D-sophoroside-7-*O*- α -L-rhamnoside and kaempferol 3-*O*-(2''- β -D-glucosyl)- β -D-rutinoside (Tang et al. 2001a), four isoflavone triglycosides, genistein 7-*O*- β -D-glucopyranoside-4'-*O*-[(α -L-rhamnopyranosyl)-(1 \rightarrow 2)- β -D-glucopyranoside], genistein 7-*O*- β -D-glucopyranoside-4'-*O*-[(β -D-glucopyranosyl)-(1 \rightarrow 2)- β -D-glucopyranoside], genistein 7-*O*- α -L-rhamnopyranoside-4'-*O*-[(α -L-rhamnopyranosyl)-(1 \rightarrow 2)- β -D-glucopyranoside] and genistein 7-*O*- α -L-rhamnopyranoside-4'-*O*-[(β -D-glucopyranosyl)-(1 \rightarrow 2)- β -D-glucopyranoside], together with nine known compounds, namely, genistein 7-*O*- β -D-glucopyranoside-4'-*O*- β -D-glucopyranoside, sophorabioside, prunetin 4'-*O*- β -D-glucopyranoside, sophoricoside, genistin, rutin, kaempferol 3-*O*- β -rutinoside, quercetin 3-*O*- β -D-glucopyranoside and kaempferol 3-*O*- β -D-glucopyranoside (Tang et al. 2001b); new flavonol triglycoside, kaempferol 3-*O*- α -L-rhamnopyranosyl-(1 \rightarrow 6)- β -D-glucopyranosyl-(1 \rightarrow 2)- β -D-glucopyranoside (1), as well as two known kaempferol 3-*O*-[α -L-rhamnopyranosyl-(1 \rightarrow 6)]- β -D-glucopyranosyl-(1 \rightarrow 2)]- β -D-glucopyranoside (2) and kaempferol 3-*O*- β -D-glucopyranosyl-(1 \rightarrow 2)- β -D-glucopyranoside-7-*O*- α -L-rhamnopyranoside (3) (Tang et al. 2002b); a coumaronochromone derivative, sophorophenolone, along with 13 known compounds, l-maackiain, medicagol, 7-*O*-methylpseudobaptigenin, pseudobaptigenin, 7,3'-di-*O*-methylorobol, genistein, prunetin, daidzein, formononetin, di-*O*-methyl-daidzein, quercetin, kaempferol and isorhamnetin (Tang et al. 2002a) were isolated from the fruit. Flavone compounds genistein-7,4'-di-*O*- β -D-glucoside (I), genistein-7-*O*- β -D-glucopyranoside-4'-*O*-[(α -L-rhamnopyranosyl)-(1 \rightarrow 2)- β -D-glucopyranoside] (II), kaempferol-3-*O*- β -D-sophoroside(III), quercetin-3-*O*- β -L-rhamnopyranosyl-(1 \rightarrow 6)- β -D-glucopyranoside (IV), genistein-4'- β -L-rhamnopyranosyl-(1 \rightarrow 2)- α -D-glucopyranoside(V) and kaempferol-3-*O*- β -L-rhamnopyranosyl-(1 \rightarrow 6)- β -D-glucopyranoside (VI) were purified from the fruit crude extract using high-speed

countercurrent chromatography combined with macroporous resin column separation (Sun et al. 2007). The purities of compounds I, II, III, IV, V and VI were 98.7, 98.2, 97.8, 98.5, 99.3 and 98.9 %, respectively, as determined by HPLC. The flavonoids kaempferol glycosides—kaempferol 3-*O*-β-glucopyranosyl(1 → 2)-β-galactopyranoside-7-*O*-α-rhamnopyranoside and kaempferol 3-*O*-β-xylopyranosyl(1 → 3)-α-rhamnopyranosyl(1 → 6)[β-glucopyranosyl(1 → 2)]-β-glucopyranoside and two tetraglycosides: kaempferol 3-*O*-β-glucopyranosyl(1 → 2)[α-rhamnopyranosyl(1 → 6)]-β-glucopyranoside-7-*O*-α-rhamnopyranoside and kaempferol 3-*O*-β-glucopyranosyl(1 → 2)[α-rhamnopyranosyl(1 → 6)]-β-galactopyranoside-7-*O*-α-rhamnopyranoside—were identified in the fruit; the latter was the main flavonoid in mature seeds (Kite et al. 2009). Three flavonoids were isolated from the fruit: sophorabioside, genistin, quercetrin (Kim and Yun-Choi 2008). Flavonoids sophorabioside, sophora-flavanolside and genistein glucoside appeared at the beginning of the fruit formation, while sophoricoside appeared only at the stage of its maturation (Balbaa et al. 2009). Rutin was found in the fruit reaching a minimum in the ripe fruits (4.3 %).

Phytoestrogens genistin, genistein, rutin, kaempferol and quercetin were determined in the fruit and seed of *S. japonica* by high-performance capillary electrophoresis with electrochemical detection (CE-ED) method (Chu et al. 2005). Detection limits ranged from 1.1×10^{-7} to 2.8×10^{-7} g/ml for all five analytes.

Seed Phytochemicals

Cytisine, *N*-methylcytisine, sophocarpine and matrine were isolated from the epigeal parts of the seed (Abdusalamov et al. 1972). Stizolamine were found in the seeds (Toshida and Hasegawa 1977). Triterpene glycosides: soyasapogenol B-3-[*O*-β-D-glucopyranosyl-(1 → 2)-*O*-β-D-glucopyranuronoside] (adzukisaponin II), soyasapogenol B [3-*O*-β-galactopyranosyl-(1 → 2)-*O*-β-L-glucopyranuronoside] (soyasaponin III), soyasapogenol B 3-(*O*-α-L-rhamnopyranosyl-

(1 → 2)-*O*-β-L-glucopyranosyl-(1 → 2)-*O*-β-D-glucopyranuronoside) (adzukisaponin V), soyasapogenol B 3-(*O*-β-D-rhamnopyranosyl-(1 → 2)-*O*-β-D-galactopyranosyl-(1 → 2)-*O*-β-D-glucopyranuronoside) (soyasaponin I) and the new glycoside (1)—soyasapogenol B 3-[*O*-β-D-glucopyranuronoside] were isolated from the seeds (Grishkovets and Gorbacheva 1995). Five triterpene glycosides with soyasapogenol B as the aglycone were isolated from the seeds (Gorbacheva et al. 1996). A new saponin 3-*O*-β-D-glucuronopyranosyl-soyasapogenol B was identified as a minor component.

Six compounds were isolated from the seed alcohol extract and identified as follows: genistein 7-*O*-β-D-glucopyranoside-4'-*O*-β-D-glucopyranoside, genistein 7-*O*-β-D-glucopyranoside-4'-*O*-[α-L-rhamnopyranosyl-(1 → 2)-β-D-glucopyranoside], tectorigenin, tectoridin, 1,6-di-*O*-galloyl-β-D-glucose and ethyl gallate (Wang et al. 2002). A flavonol tetraglycoside and kaempferol 3-*O*-α-L-rhamnopyranosyl(1 → 6)-β-D-glucopyranosyl(1 → 2)-β-D-glucopyranoside-7-*O*-α-L-rhamnopyranoside, together with nine known compounds, were isolated from the seeds (Wang et al. 2003).

Total extractive from ground ripe *S. japonica* seeds consisted of neutral lipids, polar lipids, carbohydrates, amino acids, pigments, etc. (Mukhamedova and Glushenkova 1997). Total yield of neutral lipids was 7 %, phospholipids 1.1 % of seed weight and phosphorus content of the total neutral lipids was 3.3 %. Nine phospholipid classes were detected:

lysophosphatidylcholines (lyso-PCs), phosphatidylcholines (PCs), phosphatidylinositols (PIs), phosphatidylethanolamines (PEs), *N*-acyl-phosphatidylethanolamines (*N*-acyl-PEs), *N*-acyl-lyso-phosphatidylethanolamines (*N*-acyl-lyso PEs), phosphatidic acids (PAs), phosphatidylglycerols (PGs) and D-phosphatidylglycerols (DPGs).

A high level of 16:0 and 18:2 fatty acids were found in all phospholipid samples. In the (*N*-acyl-lyso PEs), 18:2 made up 51.7 % of total acid weight. In total phospholipid, trace amount of 21:0 fatty acids were found, mainly localized in the *N*-acyl-PEs. PGs contained a higher level of SFA (64.5 %) than other phospholipids, while *N*-acyl-lyso

PEs contained the least (15.1 %) In sequence of decreasing unsaturation, the individual phospholipids were ranked as follows: *N*-acyl-lyso PEs → PCs → PEs → *N*-acyl-PEs → lyso-PCs → PIs → DPGs → PAs → PGs.

A haemagglutinin protein was purified from the seeds (Poretz et al. 1974). It was found to contain relatively large amounts of hydroxyl and acidic amino acids, no methionine and about five residues of half-cystine/mol. The presence of covalently bound carbohydrates was determined as 14–15 residues of 2-amino-2deoxyglucose and 5.9 % neutral saccharide of mannose and xylose. Seeds were found to contain *N*-acetylglucosamine-specific lectins, glycoproteins with molecular weights of about 130,000 and possessing substantial sequence homology (Mcpherson et al. 1987). The lectin isolated from *Sophora japonica* seeds was found to be a glycoprotein, its carbohydrate moiety comprising fucose, xylose, mannose and *N*-acetylglucosamine (Fournet et al. 1987). The lectin was found to bind oligosaccharides with nonreducing terminal Gal beta(1-3/4)GlcNAc beta 1 units. *S. japonica* seeds contained a GalNAc-specific lectin which was highly homologous to though not identical with the GalNAc-specific lectin from the bark (Van Damme et al. 1997). *Sophora japonica* seed was found to contain an incomplete partial phytohaemagglutinin anti-B2 of the blocking type (Potapov 2004).

Leaf Phytochemicals

Two flavonol tetraglycosides 3-*O*- α -rhamnopyranosyl(1 → 2)[α -rhamnopyranosyl(1 → 6)]- β -glucopyranoside-7-*O*- α -rhamnopyranosides of quercetin and kaempferol were isolated from the leaves of *Styphnolobium japonicum* (Kite et al. 2007). The 3-*O*- α -rhamnopyranosyl(1 → 2)[α -rhamnopyranosyl(1 → 6)]- β -galactopyranoside-7-*O*- α -rhamnopyranoside of kaempferol, the 3-*O*- α -rhamnopyranosyl(1 → 2)[α -rhamnopyranosyl(1 → 6)]- β -glucopyranosides of kaempferol and quercetin and the 3-*O*- α -rhamnopyranosyl(1 → 2)[α -rhamnopyranosyl(1 → 6)]- β -galactopy-

ranoside of kaempferol were also isolated. An additional constituent obtained was identified as the maltol derivative, 3-hydroxy-2-methyl-4*H*-pyran-4-one 3-*O*-(4'-*O*-*p*-coumaroyl-6'-*O*-(3-hydroxy-3-methylglutaroyl))- β -glucopyranoside.

Two isoflavone tetraglycosides genistein 7-*O*- β -D-glucopyranoside-4'-*O*-(6'''-*O*- α -L-rhamnopyranosyl)- β -sophoroside and genistein 7-*O*- α -L-rhamnopyranoside-4'-*O*-(6'''-*O*- α -L-rhamnopyranosyl)- β -sophoroside and six known compounds (genistein 7-*O*- β -D-glucopyranoside-4'-*O*- α -D-glucopyranoside, sophorabioside, genistin, rutin, quercetin 3-*O*- β -D-glucopyranoside and kaempferol 3-*O*- β -D-glucopyranoside) were isolated from *S. japonica* leaves (Tang et al. 2008a, b). Three flavonoids were isolated from the leaves genistein, tectoridin rutin (Kim and Yun-Choi 2008).

The rutin content decreased from young (8.7 %) to mature leaves (4.1 %) and then remained without significant changes all over flowering and fruiting seasons (Balbaa et al. 2009). Two new flavanones with a C15 isoprenoid group, japonicasins A and B (1 and 2), were isolated from the leaves (Zhang et al. 2013a) and represented the first report on the presence of the (2*E*,7*E*)-6-isopropyl-3,9-dimethyldeca-2,7,9-trien-1-yl group (C15 isoprenoid group) in isoprenylated flavonoids. The quinolizidine alkaloid, lupanine, was found in the leaves and cell cultures (Wink et al. 1983).

Two lectins, Leaf Lectin I and Leaf Lectin II (LLI and LLII), were purified from the leaves (Hankins et al. 1987). Like the *Sophora* seed lectin, LLI and LLII were found to be tetrameric glycoproteins containing a single subunit with respect to size. The subunits of LLI (32 kDa) and LLII (34 kDa) were slightly larger than those of the seed lectin (29.5 kDa). The three *Sophora* lectins displayed indistinguishable specificities, amino acid compositions, specific haemagglutinin activities and extinction coefficients. Although very closely related to the seed lectin, the leaf and seed lectins were not immunologically identical, and they differed in subunit molecular weights, carbohydrate content and in the pH sensitivity of their haemagglutinin activities. The leaf lectins

were found to be exclusively sequestered in the protein-storage vacuoles of these tissues (Herman et al. 1988).

Stem/Bark Phytochemicals

Two isoflavone triglycosides, genistein 4'-*O*-(6''-*O*- α -L-rhamnopyranosyl)- β -sophoroside and genistein 4'-*O*-(6'''-*O*- α -L-rhamnopyranosyl)- β -sophoroside, together with five known compounds, namely, sophorabioside, genistin, rutin, quercetin 3-*O*- β -D-glucopyranoside and kaempferol 3-*O*- β -D-glucopyranoside, were isolated from the small branches of *Sophora japonica* (Tang et al. 2008b). Four flavonoids were isolated from the stem: biochanin A, iridolidone, sissotrin and apigenin (Kim and Yun-Choi 2008). A new isoflavone glycoside, 6-methoxy-7-hydroxy-4'-*O*- β -D-glucosyl isoflavone, glycitein-4'-*O*- β -D-GLUCOSIDE, along with known flavonoids (daidzein, calycosin, trifolirhizin, puerol A, ononin, 5-hydroxypseudobaptigenin-7-*O*-glucoside, glycitin, calycosin-7-*O*-glucoside, paratensein-7-*O*-glucoside), were isolated from the stem bark of *Sophora japonica* (Park et al. 2010).

Five *N*-acetyl-galactosamine-specific lectins were isolated from the bark but were absent in other tissues (Hankins et al. 1988). These lectins were immunologically and structurally very similar, but not identical, to the *Sophora* seed and leaf lectins. The carbohydrate specificities and haemagglutinin activities of these lectins were indistinguishable at pH 8.5 but their activities differed markedly at pH values below 8. All five lectins were found to be tetrameric glycoproteins made up of different combinations of subunits of about 30,000, 30,100, 33,000 *M*(r) containing 3–5 % covalently attached sugar. Mannose/glucose-specific lectins were found in the bark (Van Damme et al. 1997). The bark lectins were found to be exclusively sequestered in the protein-storage vacuoles of these tissues (Herman et al. 1988). Sophoragrin, a D-mannose/D-GLUCOSE-SPECIFIC lectin (B-SJA-II), was isolated from the bark of *S. japonica* (Ueno et al. 1991). It was found to have 4 subunits a-1 (*Mr*=19,400), a-2 (*Mr*=18,200), b-1 (*Mr*=15,000) and b-2

(*Mr*=13,200). Each subunit had a sugar-binding site for the mannosyl core of N-linked oligosaccharide chains and recognized each other sugar specifically to form aggregates. Further studies showed that self-aggregation of sophoragrin was shown to be a unique homopolymerization due to the sugar-specific interaction (Ueda et al. 2004). Sophoragrin was found to sequester endogenous glycoprotein ligands via sugar-specific interactions.

Unidentified Plant Parts Phytochemicals

A new compound, *N*-feruloyl-*N'*-*cis*-feruloyl-putrescine, together with four flavonoids (rutin, quercetin, 3-methylquercetin, orobol) and three putrescine derivatives (*N,N'*-diferuloyl-putrescine, *N,N*-dicoumaroyl-putrescine and *N*-coumaroyl-*N*-feruloyl-putrescine), was isolated from *S. japonica* (Lo et al. 2009).

Root Phytochemicals

DL-maackiain and D-maackiain—mono- β -D-glucoside under the proposed name sophojaponicin, a diastereomer of trifolirhizin, were isolated from the roots (Shibata and Nishikawa 1963). *Sophora japonica* roots were found to contain anhydropisatin (flemichapparin B); irisolidone; 5,7-dihydroxy-3', 4'-methylenedioxyisoflavone; biochanin A; D-maackiain and β -sitosterol (Komatsu et al. 1976); and oxymatrine (Gan et al. 2011). An aromatic glycoside, named sophoroside A with the structure puerol B 5-*O*- β -D-glucopyranoside together with puerol A and puerol B, was isolated from the roots (Shirataki et al. 1987). Oxymatrine and matrine were found in the roots (Cheng et al. 2008).

Antioxidant Activity

A flavonol triglycoside, kaempferol 3-*O*- α -L-rhamnopyranosyl-(1 \rightarrow 6)- β -D-glucopyranosyl-(1 \rightarrow 2)- β -D-glucopyranoside,

and kaempferol 3-*O*-[α -L-rhamnopyranosyl-(1 \rightarrow 6)]-[β -D-glucopyranosyl-(1 \rightarrow 2)]- β -D-glucopyranoside and kaempferol 3-*O*- β -D-glucopyranosyl-(1 \rightarrow 2)- β -D-glucopyranoside-7-*O*- α -L-rhamnopyranoside isolated from the fruit, exhibited antioxidant activity in DPPH (2,2-diphenyl-1-picrylhydrazyl) and cytochrome-c assay using HL-60 cell system (Tang et al. 2002b). It was found that rutin administration sharply suppressed free radical production in liver microsomes and by phagocytes of iron-overloading rats and only slightly affected these processes in normal rats (Afanas'ev et al. 1995). The selective inhibitory effect of rutin under pathologic conditions induced by iron overload was thought to be due to the formation of inactive iron–rutin complexes which were unable to catalyze the conversion of superoxide ion into reactive hydroxyl radicals, a process responsible for the free-radical-mediated toxic effects of iron overload. In cholesterol-enriched erythrocytes and control erythrocytes, quercetin provided greater protection against lipid peroxidation and reactive oxygen species (ROS) formation, and it preserved better cellular integrity than rutin (López-Revuelta et al. 2006). Both antioxidants suppressed the alterations in membrane fluidity and lipid losses with similar efficiency, reducing haemoglobin oxidation by 30 % and GSH losses by 60 % in the above-mentioned erythrocytes. Cholesterol depletion reduced the efficiency of the antioxidant power of both flavonoids against oxidative damage induced in the erythrocyte membrane, while a stronger degree of protection of GSH and haemoglobin contents was observed, mainly in the presence of rutin.

Wang et al. (2008) found that the polysaccharides of *Sophora japonica* scavenged hydroxyl and superoxide anion free radicals. Of four plants, *Sophora japonica* showed significant antioxidant activity in both yeast model and also DPPH free radical scavenging methods. The ethanol extract of *S. japonica* showed highest levels of phenolics and flavonoids (91.33 GAE mg/g and 151.86 QE mg/g, respectively). A positive linear correlation between antioxidant activity and the total phenolics and flavonoid contents indicates that these compounds are likely to be

the main antioxidants contributing to the observed activities (Zhang et al. 2011).

Two new flavanones japonicasins A and B isolated from the leaves exhibited potential antioxidant DPPH radical scavenging activities, with IC₅₀ values of 35.1 and 88.7 μ M, respectively (Zhang et al. 2013a).

Antiinflammatory Activity

Five plant extracts including *S. japonica* and *S. flavescens* exhibited significant antiinflammatory activity by in-vitro inhibition of the production of NO and TNF- α with low IC₅₀ values (Zhang et al. 2011). Sophoricoside, an isoflavone glycoside isolated from immature fruits of *Sophora japonica* when administered orally at >100 mg/kg or injected intravenously at >10 mg/kg, exerted significant reduction of carrageenan-induced paw oedema in mice (Kim et al. 2003a). The anti-inflammatory effect of sophoricoside was found to be through selective inhibition of cyclooxygenase (COX)-2 activity with an IC₅₀ value of 3.3 μ M. Sophoricoside from immature *S. japonica* fruit inhibited the interleukin (IL)-6 bioactivity with an IC₅₀ value of 6.1 μ M but had no effects on IL-1 β and TNF- α bioactivities (Kim et al. 2003b). Sophoricoside was identified as a selective inhibitor of cyclooxygenase (COX)-2 activity with an IC₅₀ value of 4.4 μ M, but did not show inhibitory effect on the synthesis of COX-2. However, sophoricoside had no effect on the production of reactive oxygen species including superoxide anions and nitric oxide. The results revealed that in-vitro antiinflammatory action of sophoricoside was significantly different from that of genistein a known phytoestrogen.

Antiplatelet Activity

An antithrombotic principle was isolated from dried buds and identified as isorhamnetin (Ishida et al. 1998). Isorhamnetin increased capillary permeability and reduced platelet aggregation. Among the flavonoid compounds, biochanin A, genistein and tectoridin showed approximately

2.5–6.5-fold greater inhibitory effects on arachidonic acid (AA) and U46619-induced platelet aggregation (IC_{50} : 19.9 and 99.8 μ M; 20.3 and 53.8 μ M; 25.9 and 123.4 μ M, respectively) than acetylsalicylic acid (ASA, IC_{50} : 63.0 and 350.0 μ M) (Kim and Yun-Choi 2008). Irisolidone was an approximately 22–40-fold stronger inhibitor than ASA on AA and U46619-induced aggregation (IC_{50} : 1.6 and 15.6 μ M, respectively). All crude, parched and carbonized forms of the flowers and its extracts were found to have a haemostatic effect (Li et al. 2004). All the samples could lower capillary permeability, bleeding time and coagulation time in mice and also decreased the plasma prothrombin time in rats. All three forms of Flos Sophorae could increase fibrinogen in rats, while the three extracts inhibited the platelet aggregation rate in rats. In addition, rutin had the effect of raising the platelet count.

Immunopharmacological Activity

The isoflavone sophoricoside isolated from *Sophora japonica* at dosages of 3 and 10 mg/kg, ameliorated 2,4-dinitrochlorobenzene-induced acute and chronic contact dermatitis by 50–70 % (Lee et al. 2013). Sophoricoside mainly affected the functions of B cells rather than T cells, macrophages and dendritic cells. As signalling targets, sophoricoside inhibited the phosphorylation and degradation of I κ B α / β and the nuclear translocation of NF- κ B p65 in B cells, but not in dendritic cells and macrophages.

The haemagglutinin seed lectin was found to require eightfold greater concentration to agglutinate human type A erythrocytes than required for the agglutination of type B cells (Poretz et al. 1974). It was unable to agglutinate type O cells at a concentration 500 times greater than needed for agglutination of type B erythrocytes. The optimum pH for agglutination of type B cells was 8.3–9.0. The lectin was found to be inhibited by *N*-acetyl-D-galactosamides more easily than D-galactosides and displayed a preference for binding β anomers of these saccharides. *S. japonica* seed lectin, which demonstrated blood group specificity, was found to be more active than

concanavalin A (from *Canavalia ensiformis*) with human erythrocytes, but had a much lower reactivity than concanavalin A with murine red blood cells (Poretz and Barth 1976). Ficin treatment of human erythrocytes resulted in an increase in agglutinability by the lectin as well as causing the appearance of *S. japonica* lectin receptors on type O cells. The *S. japonica* lectin appeared to be devoid of mitogenic and immunosuppressive activity, in contrast to concanavalin A which suppressed the T helper-dependent antibody response to sheep erythrocytes. They found the native lectin to be composed of the non-covalent association of two dissimilar subunits, one subunit consisted of two identical polypeptide chains attached by two disulphide bonds and the other subunit of two identical polypeptide chains stabilized by a single cysteine bridge (Timberlake et al. 1980). *Sophora japonica* seed lectin agglutinated human B erythrocytes strongly and A₁ erythrocytes weakly (Wu et al. 1981) Bivalent metal ions such as Ca²⁺, Mn²⁺ or Mg²⁺ were shown to be essential for haemagglutinating and precipitating activities. At optimal concentrations of bivalent metal ions, haemagglutinating activity was highest between pH 8.5 and 9.0 and decreased sharply below pH 8.5, whereas precipitating capacity was maximal between pH 6.7 and 9.5. The combining site of the *S. japonica* lectin was explored by quantitative precipitin and precipitin inhibition assays.

Cardioprotective Activity

Studies showed that administration of oxymatrine to rat with acute myocardial infarction relieved myocardial injuries during ischaemia, and this was achieved by protecting cardiomyocytes from apoptotic death (Sun et al. 2008). The beneficial effects of oxymatrine were likely mediated by an inhibition of lipid peroxidation (MDA production) and an increase in endogenous antioxidant activity (SOD), activation of the survival signalling molecule (Bcl-2) and a reduction of apoptotic mediator (Fas) and intracellular Ca²⁺ overload. Intragastric administration of oxymatrine (alkaloid of *S. japonica*) to rats with acute myocardial

infarction induced by ligation of left anterior descending branch, significantly ameliorated haemodynamics, inhibited the expression of transforming growth factor beta 1 T β R(1) mRNA and Smad3 mRNA and reduced the left ventricle weight/body weight (Shen et al. 2011). The results indicated that oxymatrine might protect against myocardial fibrosis and the mechanism may involve modulation of the TGF- β (1)-Smads signal pathway. Pretreatment with oxymatrine main alkaloid component of the root markedly increased the dose of aconitine required to induce arrhythmias in rats (Gan et al. 2011). Additionally, oxymatrine significantly delayed the initial time and shortened the duration time of rat arrhythmias induced by coronary artery ligation. Cardiac mortality rate in coronary artery ligation-induced arrhythmias was also effectively decreased by oxymatrine in rats. Oxymatrine could significantly inhibit sodium and calcium currents in isolated rat cardiomyocytes in a concentration-dependent manner. It was concluded that oxymatrine played a remarkably preventive role in rat arrhythmias through the inhibition of sodium and calcium currents. Another animal study showed that oxymatrine exhibited substantial therapeutic potential for the treatment of septic shock-induced myocardial injury through inhibition of the janus kinase-signal transducer and activator of transcription (JAK/STAT) signalling pathway (Zhang et al. 2013b). It also attenuated the expression of proinflammatory cytokines, including interleukin-1 β and tumour necrosis factor- α . Moreover, oxymatrine exhibited antiinflammatory properties as heart function and myocardial contractility were improved and pathological and ultrastructural injury were prevented in myocardial tissue induced by septic shock.

Neuroprotective/Cerebral Protective Activity

Studies in rats with cerebral infarct induced by ischaemia–reperfusion showed that pretreatment with 100 or 200 mg/kg *Sophora japonica* and posttreatment with 200 mg/kg *S. japonica* significantly reduced the grade of neurological

deficit and the ratio of cerebral infarction area (Lao et al. 2005). Further, pretreatment with 200 mg/kg *S. japonica* also significantly reduced ED1 (mouse anti rat CD68) and interleukin-1beta immunostaining positive cells, and apoptotic cells in ischaemia–reperfusion cerebral infarct rats. The study demonstrated that *S. japonica* could reduce the cerebral infarction area and neurological deficit induced by ischaemia–reperfusion in rats by its suppressive action of microglia, interleukin-1beta and apoptosis, suggesting its potential as a treatment for cerebral infarct in humans. Pu et al. (2007) found both rutin and quercetin (50 mg/kg \times 2) improved spatial memory impairment in the 8-arm radial maze task and neuronal death in the hippocampal CA1 area induced by repeated cerebral ischaemia in rats; however, catechin (200 mg/kg \times 2) and (–)-epigallocatechin gallate (EGCG) (50 mg/kg \times 1) did not. Administration of EGCG (50 mg/kg \times 2) resulted in a high mortality rate. These results suggested that in this repeated cerebral ischaemia model, the 4-oxo group and the 2,3-double bond in the C ring of rutin and quercetin were related to their neuroprotective action.

Studies found that *Sophora japonica* flower extract reduced the size of cerebral infarction and neurological deficits and reduced microglial activation, interleukin-1 β release and number of apoptotic cells in ischaemia–reperfusion injured Sprague–Dawley rats (Chen and Hsieh 2010). Studies suggested that *S. japonica* contained both antihaemorrhagic and antihaemostatic substances and reduced cerebral infarction partly as a result of its antioxidative and antiinflammatory activities. The results of animal studies suggested that the neuroprotective effect of rutin on trimethyltin-induced spatial memory impairment could be attributable to its inhibitory effect against microglial activation and its role in synapse formation via neurotrophic factors in the hippocampus (Koda et al. 2009).

Pulmoprotective Activity

Pretreatment of mice with oxymatrine (*S. japonica* alkaloid) significantly alleviated oleic

acid-induced acute lung injury which was characterized by prominent atelectasis, intra-alveolar and interstitial patchy haemorrhage, oedema, thickened alveolar septum, formation of hyaline membranes and the existence of inflammatory cells in alveolar spaces (Xu et al. 2005). This attenuation was accompanied by reduction of lung index and wet-to-dry weight ratio, decreases in serum TNF- α level and inhibition of phosphorylated p38 MAPK. The findings suggested that oxymatrine had a beneficial effect on acute lung injury induced by oleic acid in mice and may inhibit the production of proinflammatory cytokine, TNF- α , by means of the inhibition of p38 MAPK. In another study, administration of oxymatrine to mice with bleomycin-induced lung fibrosis inhibited the proliferation of murine lung fibroblasts, arrested the cells at G(0)/G(1) phase and reduced the expression of cell-cycle regulatory protein, cyclin D1 (Chen et al. 2008). In addition, the steady-state production of collagen and the expression of α 1(I) pro-collagen and α 2(I) pro-collagen mRNA in fibroblasts were inhibited by oxymatrine in a dose-dependent manner. The results suggested that oxymatrine may attenuate pulmonary fibrosis induced by bleomycin in mice, partly through inhibition of inflammatory response and lipid peroxidation in lung induced by bleomycin and reduction of fibroblast proliferation and collagen synthesis.

Antitumour Activities

Among 11 isoflavones of *Sophora* species tested, genistein produced high cytotoxic activity against human oral tumour cell lines (HSC-2, HSG; CC_{50} =31,54 μ g/ml, respectively) than against normal cells (human gingival fibroblast, HGF; CC_{50} =401 μ g/ml), suggesting its tumour-specific action (Shirataki et al. 2001). Biochanin A also showed high cytotoxicity activity against human oral tumour cell lines (HSC-2, HSG; CC_{50} =26, 125 μ g/ml). Daidzein and formononetin showed weak cytotoxic activity against human oral tumour cell lines (HSC-2, HSG; (CC_{50} =114, 117; 596,584 μ g/ml, respectively) but much weaker cytotoxicity against normal cells HGF (CC_{50} =625,

726 μ g/ml respectively) indicating their tumour-specific action. Calycosin (HSC-2, HSG; CC_{50} =179,142 μ g/ml) and 7,4'-dihydroxy-3'-methoxyisoflavone (HSC-2, HSG; CC_{50} =500,524 μ g/ml) showed weak activity comparable to daidzein and formononetin. Licoisoflavone A (HSC-2, HSG; CC_{50} =25,31 μ g/ml) and 6,8-diprenylgenistein (HSC-2, HSG; CC_{50} =10,13 μ g/ml) highest cytotoxic activity but lower tumour specificity. Sophoraisoflavone (HSC-2, HSG; CC_{50} =26,26 μ g/ml) and licoisoflavone A (HSC-2, HSG; CC_{50} =11, 19 μ g/ml) also showed higher cytotoxicity but reduced tumour specificity. Matrine-induced apoptosis in human hepatoma Hep G2 cells in a time- and dose-dependent manner through the mitochondrial pathway, and oxidative stress via depletion of glutathione (GSH) directly involved in the apoptotic process (Cheng et al. 2008). Matrine induced the release of cytochrome c from mitochondria to cytoplasm and then stimulated the cleavage of Caspase-9 in a time-dependent manner.

Both collagen synthesis and Smad3 production in human keloid fibroblasts were significantly suppressed in a dose-dependent administration of oxymatrine, alkaloid extracted from *S. japonica* (Fan et al. 2012). Oxymatrine reversed phosphorylation and nuclear translocation of Smad3 induced by TGF- β 1. Oxymatrine inhibitory effect in collagen synthesis might be associated with TGF- β /Smad signalling pathway. The results suggested that oxymatrine may be a promising candidate to prevent keloid and other fibrotic diseases. Keloids are benign dermal tumours characterized by fibroblastic proliferation and excessive accumulation of collagen.

Antiviral Activity

Of 11 *Sophora* isoflavones, licoisoflavone A (CC_{50} =33 μ g/ml) and sophoraisoflavone A (CC_{50} =55 μ g/ml) showed high higher anti-*Helicobacter pylori* activity but lower than clarithromycin (CC_{50} =10 μ g/ml) (Shirataki et al. 2001). Other isoflavones were inactive. All 11 isoflavones failed to induce antihuman immunodeficiency virus (HIV) activity.

In 22 patients with chronic hepatitis B treated with oxymatrine 0.4 g/daily by intramuscular injection for 3 months, the seroconversion rate of HBV (hepatitis B virus) DNA and HBeAg (hepatitis B early antigen) in the treated group was 43.47 and 43.47 %, respectively, which was way better than those in the untreated control group respectively (Chen et al. 2002). The study showed that oxymatrine effective in treating chronic hepatitis B. The therapeutic effect was better for patients with lower quantity of serum HBV DNA. In another randomized clinical trial, 253 patients with chronic hepatitis B treated with intravenous or intramuscular injection of oxymatrine and oral oxymatrine capsule showed improvement in liver function, and the negative rate of HBeAg and HBV DNA were increased (Yu et al. 2001). The therapeutic effect of oxymatrine persisted after the cessation of treatment. In a randomized double-blind and placebo-controlled multicenter trial of 199 patients with chronic hepatitis B, administration of oxymatrine injection or oral capsule was found to be safe and efficacious (Lu et al. 2003). In the capsule-treated patients, 76.47 % became normal in ALT level and 38.61 and 31.91 % became negative both in HBV DNA and in HBeAg. In the injection-treated patients, 83.33 % became normal in ALT level and 43.33 and 39.29 % became negative both in HBV DNA and in HBeAg. In the placebo-treated patients, 40.00 % became normal in ALT level and 7.46 and 6.45 % became negative both in HBV DNA and in HBeAg. The rates of complete response and partial response were 24.51 and 57.84 % in the capsule-treated patients, 33.33 and 50.00 % in the injection-treated patients and 2.99 and 41.79 % in the placebo-treated patients, respectively.

Hepatoprotective Activity

Xiang et al. (2002) showed that oxymatrine protected mice from fulminant hepatitis induced by GalN/LPS (galactosamine/lipopolysaccharide) and may block hepatocyte apoptosis and subsequent necrosis through downregulating the production of serum tumour necrosis factor alpha

and the expression of Fas and Fas ligand in liver tissue. Similarly in another study, Jiang et al. (2005) reported that the antiapoptotic activity of oxymatrine protects the liver from warm ischaemia–reperfusion injury in rats mainly by downregulation of Fas and Fas ligand in liver tissues. Similar results were also obtained by Meng et al. (2005), wherein oxymatrine protected rats against ischaemia–reperfusion injury of liver by antiapoptotic activity via downregulation of Fas protein expression.

Intestinal Protective Activity

Studies showed that oxymatrine could attenuate intestinal ischaemia–reperfusion injury induced in rats (Zhao et al. 2008). The oxymatrine-treated group had a significantly lower histological score and apoptosis index than the saline group, demonstrating that the pre-administration of oxymatrine attenuated gut damage. Moreover, oxymatrine inhibited the production of lipid peroxides (LPO), decreased the serum levels of tumour necrosis factor (TNF)-alpha and downregulated expression of phosphorylated p38 mitogen-activated protein kinase, Fas and FasL, which had been elevated by ischaemia–reperfusion.

Renoprotective Activity

Studies showed that matrine exhibited a renoprotective effect on experimental glomerulosclerosis in rats, probably through the reduction of the transforming growth factor-beta1 (TGF-beta1) negative function via connective tissue growth factor, which inhibited the activation and proliferation of glomerular intrinsic cells, and decreasing the secretion of extracellular matrix proteins accordingly (Zhang and Jin 2004). Administration of oxymatrine inhibited adriamycin-induced chronic renal fibrosis in rats and functional impairment by downregulating NF-kappaB expression, which may play a key role in protection against renal fibrosis (Chen and Jin 2007).

Antidiabetic Activity

Among compounds isolated from the stem bark, daidzein, puerol A and paratensein-7-*O*-glucoside exhibited potent aldose reductase inhibitory effects, with IC₅₀ values of 3.2, 6.4 and 1.9 µM, respectively (Park et al. 2010).

Antibacterial Activity

The ethanol extract of *S. japonica* flower buds exhibited marked antibacterial activity against *Propionibacterium acnes*, *Propionibacterium avidum* and *Staphylococcus aureus* under weak acidic conditions (Kimura and Yamada 1984). The bioactive principles were found to be quercetin, rutin and isorhamnetin-3-rutinoside.

Oestrogenic Activity

Sophora japonica methanol extract showed oestrogenic effect only after naringinase treatment (El-Halawany et al. 2011). The naringinase-treated methanol extract of *Sophora japonica* seeds showed potent oestrogen agonist activity (El-Halawany et al. 2010). The aglycones genistein and kaempferol were found to be the main phytoestrogens in the naringinase-treated methanol extract. Additionally, kaempferol was nearly equipotent to genistein as an oestrogen agonist. Sophoricoside isolated from the untreated methanol extract showed weak oestrogenic activity on ERβ only.

Antiobesity Activity

Administration of a diet containing *Sophora japonica* fruit to high-fat diet-induced obese mice for 4 weeks significantly decreased body weight gain (Park et al. 2009). *S. japonica* also reduced serum and hepatic triglyceride, serum total and high-density lipoprotein cholesterol, glucose level and fat mass and caused a decrease in the number of large adipocytes and a concomitant increase in the number of small adipocytes,

which may explain at least in part the antiobesity effects. The results indicated a potential role of *S. japonica* in the control of body weight and obesity-related metabolic diseases. The ethyl acetate fraction fruit extracts inhibited morphological differentiation and lipid accumulation in the C3H10T1/2 mesenchymal stem cells and 3 T3-L1 preadipocytes (Jung et al. 2011). The fraction also reduced the expression of peroxisome proliferator-activated receptor γ and other adipocyte markers. The fraction was found to have the highest total phenol contents, suggesting that the polyphenols in the fraction mediated the anti-adipogenic effects. Genistein, a known anti-adipogenic compound, was identified in the fractions and suggested to be probable mediator of the anti-adipogenic effects of the ethyl acetate fractions. The results validated the beneficial roles of *S. japonica* in controlling body weight and obesity-related metabolic diseases.

Skin Whitening (Tyrosinase Inhibitory) Activity

Sophora japonica extract showed inhibition of mushroom tyrosinase activity in-vitro (Lee et al. 1997). Four herbs, *Pharbitis nil*, *Sophora japonica*, *Spatholobus suberectus* and *Morus alba*, exhibited potent inhibitory effects on tyrosinase (IC₅₀ values 24.9, 95.6, 83.9 and 78.3 µg/ml, respectively) (Wang et al. 2006a). Melanin inhibition was not dose dependent. *Sophora japonica* (IC₅₀: 14.46 µg/ml, DPPH; 1.95 µg/ml, hydroxyl radical) and *Spatholobus suberectus* (IC(50): 10.51 µg/ml, DPPH; 4.36 µg/ml, hydroxyl radical) showed good antioxidative activities and high phenolic contents (255 and 189 mg of gallic acid/g extract, respectively). Among active anti-tyrosinase extracts, *Sophora japonica* and *Spatholobus suberectus* were especially potent in human epidermal melanocyte cells in terms of free radical scavenging effects and high phenol contents, making them the strongest candidates for cosmetic application found in the study. A putrescine compound, *N*-feruloyl-*N'*-*cis*-feruloyl-putrescine, was minimally cytotoxic (cell viability >90 % at 100 µM) and the IC₅₀

value for suppression of cellular tyrosinase activity in human epidermal melanocytes was estimated at 85.0 μM (Lo et al. 2009).

Antiosteoporotic Activity

Nine weeks after oral administration of *S. japonica* fruit extract to ovariectomized rats, elevated deoxypyridinoline level was significantly decreased and Ca levels were elevated compared to control (Shim et al. 2005). Further trabecular bone area (TBA) in the tibia and lumbar was also increased compared with control group. The preventive or treatment effects of Sophorae Fructus extracts on bone loss in ovariectomized rats appeared to be due to suppression of bone turnover.

Treatment of SD rats with a 4.5 or 9 mg/kg dosage of genistein (extracted from *S. japonica*) prevented osteoporosis significantly at the fourth week after treatment (Wang et al. 2006b). In comparison with the anti-osteoporosis effects of soybean genistein, the genistein extracted from Huaijiao had the same beneficial effect on anti-osteoporosis.

Interleukin-5 Inhibitory Activity

Fruits of *Sophora japonica* exhibited an inhibitory effect in the interleukin IL-5 bioassay of mIL-5-dependent Y16 proliferation; the isoflavonoids of sophoricoside, genistein, orobol and genistin were isolated as the IL-5 inhibitors from the fruits (Min et al. 1999). Among the IL-5 inhibitors, sophoricoside exhibited the highest inhibitory effect with 89 % inhibition at 12.5 μM , 82 % at 6.3 μM , 72 % at 3.1 μM , 59 % at 1.6 μM and 24 % at 0.8 μM where the 50 % inhibition (IC_{50}) was shown at the concentration of 1.5 μM . In the order of IC_{50} values, the inhibitory potency in the IL-5 bioassay was sophoricoside > orobol (9.8 μM) approximately equal to genistein (10.6 μM) > genistein (51.9 μM).

Analgesic Activity

Puerol A isolated from the roots, greatly inhibited 3 h-ethyl ketocycloazocine on the receptor-

binding assay test and so may be developed as a nonaddictive analgesic (Shirataki et al. 1987).

Alleviation of Postmenopausal Symptoms

In a randomized double-blind placebo-controlled clinical trial, consumption of Rexflavone (*S. japonica* fruit extract) was found to possess beneficial effects on the postmenopausal symptoms in postmenopausal women (Lee et al. 2010). Rexflavone significantly improved 11 menopausal symptoms including hot flash, which was evaluated by the modified Kupperman Index (KI), while hormone level and lipid profile were little altered by consumption. Rexflavone had no adverse effect and appeared to be safe for long-term consumption.

Radioprotective Activity

A mixture of *Sophora japonica* and pantocrine exhibited the highest radioprotective effect in irradiated (2.5 Gy) human lymphoblastoid cells when injection 15 minutes after irradiation which was more effective than preinjection (Narimanov et al. 1990). *Sophora japonica* and pantocrine were shown to increase the survival rate of lethally exposed mice ($\text{LD}_{90/30}$) when administered in a combination 5–15 minutes before irradiation. Similar radioprotective effects were found with *Sophora japonica* and its combination with an antioxidant vitamin complex administered enterally to mongrel male rats exposed to whole-body gamma-radiation (7, 9 and 11 Gy) (Sokol'chik et al. 1992).

Traditional Medicinal Uses

Sophora japonica is commonly used in traditional Chinese medicine and is considered to be one of the 50 fundamental herbs (Duke and Ayensu 1985). The flowers and flower buds are astringent, antibacterial, anticholesterolaemic, antiinflammatory, antispasmodic, haemostatic,

antihaemorrhagic, oestrogenic and hypotensive (Stuart 1979; Duke and Ayensu 1985; Bown 1995; Vo 1997; WHO 1998; Tran 1999; Le and Nguyen 1999). They have been reputed as therapeutic relief for various types of haemorrhages (e.g. haemoptysis, epistaxis, haematuria, haematochezia, haemorrhagic haemorrhoids, metrorrhagia) and are also useful for the treatment of hypertension, poor peripheral circulation, ophthalmia and intestinal worms. Flower buds and young pods are an important source of rutin, which has 'vitamin P'-like properties and is used in the treatment of conditions characterized by increased capillary permeability and fragility. The seedpods are abortifacient and the underlying reason for the second ranking of the plant in a study of 250 potential antifertility agents in China (Duke and Ayensu 1985). The seed is emetic and haemostatic and employed in the therapy of haemorrhoids, haematuria, uterine bleeding, constipation, stuffy sensation in the chest, dizziness, red eyes, headache and hypertension. The leaves are laxative and used in the therapy of epilepsy and convulsions. A stem decoction is employed for piles, sore eyes and skin problems. Oxymatrine an alkaloid from *Sophora japonica* has been used to treat inflammatory diseases and various types of cancer in traditional Chinese medicine (Zhang et al. 2013b).

Other Uses

In northern China it is used as component of agroforestry systems. In northern Indochina, the tree was planted in the villages for obtaining raw material for paper production. In temperate and subtropical regions around the world, the Japanese pagoda tree is commonly cultivated as an ornamental and shade trees in gardens and parks and as a road-side tree, in large parking lot islands, median strip plantings in highways or as a buffer strips around parking lots. The pagoda tree is also widely used in bonsai gardening. The shoots and leaves appeared to be suitable as fodder. The wood is durable and tough and can be used for window and door frames and for

agricultural implements. The flower buds can be used for dyeing yellow or a beautiful granite grey. Mixed with indigo, the dye gives a green colour. In China and Vietnam this dye was formerly important for dyeing silk, embroidery thread and hat tassels. In Java, dried flower buds were imported from China for the batik industry. In the fine 'soga-batik' process, they were used in the last fixing and colouring bath after the real colouring process, in a mixture together with rice flour, camphor, lime juice, sugar and water. In China, extracts of the leaves and pods are used to adulterate opium.

Comments

The tree is propagated by seeds which germinate readily after scarification or soaking treatment with hot water. Grafting, layering, greenwood and root cuttings are used for the ornamental cultivars. Trees can be coppiced successfully.

Trifolium pratense

Scientific Name

Trifolium pratense L.

Synonyms

Trifolium borysthenicum Gruner, *Trifolium bracteatum* Schousb., *Trifolium lenkoranicum* (Grossh.) Roskov, *Trifolium pratense* var. *lenkoranicum* Grossh., *Trifolium ukrainicum* Opperman

Family

Fabaceae, also placed in Papilionaceae

Common/English Names

Beebread, Broad-Leaved Clover, Chilean Clover, Cow Clover, Cowgrass Clover, Early Blooming Clover, June Clover, King's Crown, Mammoth Clover, Mammoth Red Clover, Meadow Clover, Meadow Honeysuckle, Meadow Trefoil, Medium Red Clover, Multi-Cut Clover, Peavine Clover, Purple Clover, Red Clover, Sweet Clover, Sweet Kitty Clover, Wild Clover

Vernacular Names

Arabic: Barsym 'Āhamar

Brazil: Trevo Dos Prados

Chinese: Hong Che Zhou Cao, Hong San Ye Cao

Czech: Jetel Luční, Jetel Luční Červený

Danish: Rød-Kløver, Rødkløver

Dutch: Rode Klaver

Eastonian: Aastristik

Esperanto: Ruĝa Trifolio, Trifolio Ruĝa

Finnish: Nurmiapila, Puna-Apila

French: Trèfle Commun, Trèfle Des Prés, Trèfle Rouge, Trèfle Violet, Triolet

Gaelic: Seamair Dhearg

German: Feldknopperrn, Fleischklee, Futterklee, Himmelsbrot Honigklee, Hummellust, Rot-Klee, Rotklee, Roter Wiesen-Klee, Steyrerklee, Sügerli, Wiesen-Klee, Weissklee, Zuckerblümli, Zuckerbrot

Greek: Trifilli To Limonio

Hebrew: Tiltan

Hungarian: Réti Here, Lóhere, Vörös Here

Icelandic: Rauðsmari

India: Laal Tipatiya Ghaas, Tripatra ([Hindi](#))

Italian: Trifoglio Dei Prati, Trifoglio Pratense, Trifoglio Rosso, Trifoglio Violetta

Japanese: Aka Kurooba, Aka Tsume Kusa, Aka-Tsumekusa, Murasaki-Tsumekusa Murasaki Tsume Kusa, Reddo Kurooba

Korean: Bulgeuntokkipul

Mexico: Trébol De Los Prados

Norwegian: Raudkløver, Rødkløver Sukkertopp, Sukkertust, Søtekolle

Polish: Konieczyna Czerwona, Konieczyna Łąkowa

Portuguese: Pé-De-Lebre, Trevo-Comum, Trevo-Dos-Prados, Trébol Pratense, Trevo-Violeta

Russian: Klever Krasnyj, Klever Lugovoi

Slovačcina: Črna Detelja, Detelja Črna

Slovincina: Ďatelina Lúčna

Spanish: Trébol Común, Trébol Morado, Trébol Rojo, Trébol Violeta

Swedish: Amerikansk Rödklöver, Rödklöve

Taiwan: Hong Shu Cao

Turkish: Çayır Dutu, Çayır Üçgülü, Dirfil, Yonca

Vietnamese: Chẽ Ba Đồng Cỏ; Ba Chẽ Đỏ

Welsh: Meillion Coch

(Facciola 1990). Roots can be eaten cooked (Kunkel 1984; Schofield 2003).

The high quercetin concentration and soyasaponin occurrence make the seeds of some *Trifolium* species (*T. repens*, *T. pratense*) a potential source of health beneficial phytochemicals for use in human nutrition (Sabudak and Guler 2009).

Origin/Distribution

Red clover is indigenous to Europe, western Asia and northwest Africa but has been introduced and naturalized in many other parts of the world.

Agroecology

Red clover favours cool weather conditions. It is well-adapted to a wide range of soil types and conditions. It tolerate wet conditions but thrives best in well-drained fertile soils. It is found in meadows, wet and dry grassland, woodland, forest margins, field borders, roadsides and paths and widely planted as pastures.

Edible Plant Parts and Uses

Leaves and young flowering heads are edible raw or cooked (Hedrick 1972; Tanaka 1976; Launert 1981; Facciola 1990). The young leaves are harvested before the plant comes into flower and are used in salads and soups or cooked like spinach (Launert 1981). The leaves can be dried, powdered and sprinkled on foods such as boiled rice (Facciola 1990). The dried leaves impart a vanilla flavour to cakes (Schofield 2003). Young flowering heads can be eaten raw in salads (Cribb and Cribb 1976; Schofield 2003). Some recipes with clover flowers are lentil and clover risotto and cauliflower and clover cheese (Roberts 2000). Fresh or dried flowers can be made into a delicate sweet herbal tea (Lust 1974; Facciola 1990). Flowers and seed pods can be dried, ground into a powder and used as a flour. The seeds can be spouted and used in salads

Botany

A herbaceous pubescent to glabrescent perennial, with erect to ascending stems, 20–80 cm high and with a fairly deep tap root. Leaves are alternate, trifoliate, basal and cauline, long petiolate in lower leaves, shortly petiolate in upper leaves with membranous, ovate-lanceolate stipules (Plates 1, 2, 3, and 4). Leaflets ovate-elliptic or obovate, 15–30 mm long by 8–15 mm broad, green with a characteristic pale inverted v-pattern in the outer half of the leaflet, base broadly cuneate, margins obscurely serrulate, apex obtuse, rarely retuse. Flowers 30–70, in dense globose or ovoid, terminal, sessile to shortly pedunculate heads, subtended by involucre of stipules (Plates 2, 3, and 4). Calyx with subulate teeth, pubescent or glabrous. Corolla purple or dark pink, standard spatulate, ovary elliptic. Legume ovoid with one yellowish-brown ovoid seed.

Nutritive/Medicinal Properties

Plant Phytochemicals

From the plant, glucose, galactose, arabinose, xylose and mannose and amino acids phenylalanine, leucine, isoleucine, methionine, aspartic

Plate 4 Top view of flower head (David Llyod)

acid, proline, alanine and histidine were found (Kazakov and Samokish 1980). Phytin and a mixture of Ca and Mg salts of inositol phosphate were also isolated. The amount of ash in the herbage of clover was 8.4 % and the amount insoluble in HCl was 1.5 %. The amounts of macroelements ($\text{mg}^{-1}\%$) determined were K^+ 1620, Na^+ 310, Ca^{2+} 1240 and Mg^{2+} 1090. The oil yield for *T. pratense* was small 0.018 % (weight/fresh weight basis) (Tava et al. 2009). Several classes of compounds were found in the oil, including alcohols, aldehydes, ketones, terpenes, esters, hydrocarbons, phenolics and acids.

A total of eleven flavonoids were identified by liquid chromatography–electrospray mass spectrometry: genistin, isoquercitrin, ononin, daidzein, sissotrin, formononetin, biochanin A, pratensein, pectolinarigenin, pseudobaptigenin and hyperoside (He et al. 1996). The following isoflavones were isolated from red clover: prunetin, irilone, biochanin A, formononetin, pratensein, genistein, calycosin and daidzein (Huang and Tu 2004).

Isoflavone compounds identified in the methanol/water (7:3 v/v) extract of red clover included daidzein, genistin, daidzein, glycitein, orobol, calycosin, genistein, pratensein, pseudobaptigenin, formononetin, texasin, irilone, prunetin, biochanin A, trifoside (prunetin-4'- O - β -D-glucoside), daidzein-7- O - β -D-glucoside-6"- O -malonate, daidzein-7- O - β -D-glucoside-6"- O -acetate, glycitin-7- O - β -D-glucoside, genistein-7- O - β -D-glucoside-6"- O -malonate, calycosin-7- O - β -D-

glucoside, calycosin-7-*O*- β -D-glucoside-6''-*O*-malonate, prunetin-4'-*O*- β -D-glucoside-6''-*O*-malonate, prunetin-4'-*O*- β -D-glucoside-6''-*O*-acetate, pratensein-7-*O*- β -D-glucoside, pratensein-7-*O*- β -D-glucoside-6''-*O*-malonate, pseudobaptigenin-7-*O*- β -D-glucoside, pseudobaptigenin-7-*O*- β -D-glucoside-6''-*O*-malonate, pseudobaptigenin-7-*O*- β -D-glucoside-6''-*O*-acetate, orobol-7-*O*- β -D-glucoside-6''-*O*-malonate, 3-methylorobol, 3-methylorobol-7-*O*- β -D-glucoside, 3-methylorobol-7-*O*- β -D-glucoside-6''-*O*-malonate, irilone-4'-*O*- β -D-glucoside, irilone-4'-*O*- β -D-glucoside-6''-*O*-malonate, irilone-4'-*O*- β -D-glucoside-6''-*O*-acetate, irilin B-5,7,2'-trihydroxy-6-methoxyisoflavon-7-*O*- β -D-glucoside, irilin B-5,7,2'-trihydroxy-6-methoxyisoflavon-7-*O*- β -D-glucoside-6''-*O*-malonate, sissotrin (biochanin A-7-*O*- β -D-glucoside), rormosin-7-*O*- β -D-glucoside, afrormosin-7-*O*- β -D-glucoside-6''-*O*-malonate, formononetin-7-*O*- β -D-glucoside-6''-*O*-acetate, formononetin-7-*O*- β -D-glucoside-6''-*O*-malonate, ononin (formononetin-7-*O*- β -D-glucoside), isomer (formononetin-7-*O*- β -D-glucoside-6''-*O*-malonate), isomer (formononetin-7-*O*- β -D-glucoside-6''-*O*-malonate), isomer (formononetin-7-*O*- β -D-glucoside-6''-*O*-acetate), texasin-7-*O*- β -D-glucoside-6''-*O*-malonate, biochanin A-7-*O*- β -D-glucoside-6''-*O*-malonate, and biochanin A-7-*O*- β -D-glucoside-6''-*O*-acetate (Klejdus et al. 2001).

Thirty-one isoflavones were found in red clover leaves and stem: daidzein-G (daidzein), glycitein-G (glycitin), genistein-G (genistin), daidzein-G-M, calycosin-G-M, pratensein-G-M, pseudobaptigenin-G, formononetin-G (ononin), genistein-G-M, pratensein-G-M, daidzein, glycitein, irilone-G, calycosin, pseudobaptigenin-G-M, formononetin-G-M, formononetin-G, biochanin A-G, prunetin-G, genistein, irilone-G-M, irilone-G-M, irilone-G-M, biochanin A-G-M, prunetin-G-M, pseudobaptigenin, biochanin A-G-M, formononetin, irilone, prunetin and biochanin A, where G represents glucosyl or galactosyl moiety, and M, malonyl (in general, glucosyl group, occasionally galactosyl group, was substituted on 7/4' position of aglycone and malonyl group was linked to 6'' position of sugar moiety) (Wu et al. 2003). Twenty-five isoflavones were detected in the roots except for daidzein,

daidzein-G-M, biochanin A-G-M, prunetin-G, prunetin and biochanin A. Twenty-six were found in the flowers except for daidzein, glycitin, genistin, daidzein-G-M and prunetin.

Different red clover cultivars showed significantly different concentrations of individual and total isoflavones (Tsao et al. 2001). The leaf contained the highest overall concentration, followed by the stem, petiole and flower. Biochanin A and formononetin were the predominant isoflavones in all cultivars and all parts, along with eight other minor aglycones, daidzein, genistein, glycitein, irilone, orobol, pratensein, pseudobaptigenin and prunetin, and four minor malonyl glycosides, genistein-7-glucoside-6''-malonate, orobol-7-glucoside-6''-malonate, formononetin-7-glucoside-6''-malonate and biochanin A-7-glucoside-6''-malonate. The isoflavone compositions and concentrations were also found to be different between red clover parts harvested at the early bud stage and the late flowering stage. Clover tissues were found to be rich in the isoflavonoids formononetin and biochanin A, particularly in plants left to wilt for 24 hours (Flythe and Kagan 2010).

The isoflavonoids prunetin, genistein, prunetin-4'-*O*- β -D-glucopyranoside, prunetin-4'-*O*- α -D-glucopyranoside, genistein-7-*O*- β -D-galactopyranoside and (+)-pinitol (1R,2S,3s,4S,5S,6r)-6-methoxycyclohexane-1,2,3,4,5-pentaol were isolated from the aerial parts (Drenin et al. 2011). Concentrations of isoflavones (μ g/g) in red clover leaves were daidzein 42 μ g, daidzein 0 μ g, genistin 560 μ g, genistein 0 μ g, formononetin-7-*O*- β -D-glucoside-6''-*O*-malonate (FGM) 4900 μ g, ononin 970 μ g, formononetin 600 μ g, biochanin A-7-*O*- β -D-glucoside-6''-*O*-malonate (BGM) 3300 μ g, sissotrin 540 μ g and biochanin A 330 μ g (de Rijke et al. 2001). The two main isoflavones in red clover were FGM and BGM. Both were subject to decomposition according to formononetin-7-*O*- β -D-glucoside-6''-*O*-malonate (FGM) \rightarrow ononin (FG) \rightarrow formononetin (F) and biochanin A-7-*O*- β -D-glucoside-6''-*O*-malonate (BGM) \rightarrow sissotrin (BG) \rightarrow biochanin A (B). The main isoflavones in leaf extracts of *T. pratense* were biochanin A and formononetin, their 7-*O*-glucosides,

and two glucoside malonate isomers of each of them (de Rijke et al. 2004). The two formononetin glucoside malonate isomers were identified as 7-*O*- β -D-glucoside 6''-*O*-malonate and 7-*O*- β -D-glucoside 4''-*O*-malonate. The biochanin A glucoside malonate isomers had different structures. The main and later eluting isomer was biochanin A 7-*O*- β -D-glucoside 6''-*O*-malonate, and the minor and earlier eluting isomer is 5-hydroxy-7-methoxyisoflavone 4'-*O*- β -D-glucoside 4''-*O*-malonate. The most prominent isoflavones found in red clover were formononetin and biochanin A and their corresponding glucosides and malonyl glucoside esters (Swinny and Ryan 2005). They found that postharvest freeze-drying inhibited the conversion of the glycosides to the aglycones, while vacuum drying allowed for maximum conversion of the glycosides to their corresponding aglycones. Air drying produced a low level of the aglycones formononetin and biochanin A, and oven drying promoted decarboxylation of the malonyl glucosides to the acetyl glucosides. Exposure to enhanced UV-B radiation resulted in an increase in total formononetin and biochanin A isoflavone levels, indicating that harvest during a period of high ambient UV-B radiation may be appropriate for maximum yield. The levels of caffeic acid and flavonols also increased by about 40 and 250 %, respectively, on exposure to enhanced UV-B radiation.

The emission of 24 compounds comprising monoterpenes, homoterpenes, esters, hydrocarbons and aldehydes from red clover plant was quantified in the laboratory, of which eight showed increased emission rates after herbivory by *Spodoptera littoralis* caterpillars (Kigathi et al. 2009). The most abundant compounds included the monoterpene (*E*)- β -ocimene (30–50 % of the total), the isomeric monoterpene (*Z*)- β -ocimene, the monoterpene linalool, the sesquiterpene (*E*)- β -caryophyllene, the sesquiterpene-derived homoterpene 4,8-dimethyl-1,3,7-nonatriene (DMNT), (*E,E*)- α -farnesene, 1-octen-3-ol, and methyl salicylate. Other compounds included α -pinene, sabinene, β -pinene, limonene, 1,8-cineole, indole, (*Z*)-jasmones, (*E*)- β -farnesene, germacrene D, (*Z*)-3-hexenyl acetate, benzyl alcohol, dodecane, undecane, octylaldehyde, nonanal and decanal.

Volatile components of red clover hay and silage comprised alkanes, alkenes, aldehydes, alcohols, ketones, esters, acids, terpenes, unidentified compounds and others (Figueiredo et al. 2007). In hay, reductions of the percentages of alcohols, such as 3-methylbutanol and 1-hexanol, of aldehydes and of low boiling point ketones were observed. A sesquiterpene (β -farnesene; ca. 10 %) and a phytol degradation product (6,10,14-trimethyl-2-pentadecanone; ca. 12 %) were the most abundant compounds detected in hay. In silage, as a result of the fermentation of fresh red clover, esters (ca. 46 %) were a more representative class of compounds. Silage esters included methyl esters, ethyl esters, acetates, non-linear esters, phenylethyl esters and others.

A synthetic pyridine derivative, 2-(2-fluoro-6-nitrobenzylsulfanyl) pyridine-4-carbothioamide, was found to be a good elicitor of isoflavonoid production in red clover suspension culture (Kašparová et al. 2012). After 48-hours application of 1 μ mol/l concentration, maximum contents of genistin (11.60 mg/g DW), daidzein (8.31 mg/g DW) and genistein (1.50 mg/g DW) were recorded, and the production of these isoflavonoids was significantly increased, when compared with the control, by 152, 151 and 400 %. The tested substance showed to be an effective elicitor of phenylpropane metabolism.

Leaf Phytochemicals

The leaves were found to contain 81 % water, 4 % protein, 0.7 % fat, 2.6 % fibre and 2 % ash (Duke and Ayensu 1985). Based on over 500 analyses, Miller (1958) reported that green red clover forage had the following nutrient composition: 12.4–34.87 % protein (av. 18.2), 3.2–5.9 % fat (av. 4.0 %), 12.7–30.8 % crude fibre (av. 24.2), 7.0–13.6 % ash (av. 8.8), and 37.1–49.7 % N-free extract (av. 44.8 %), 0.58–3.21 % Ca (av. 1.76), 0.24–0.53 % P (av. 0.29), 1.49–2.94 % K (av. 2.10 %), 0.36–0.57 % Mg (av. 0.45), 0.016–0.032 % Fe (av. 0.03), 7.3–10.3 ppm Cu (av. 8.8 ppm), and 121–464 ppm Mn (av. 159 ppm). The leaf-protein concentrate (59 % protein) comprised 6.4 % arginine, 2.5 % histidine, 5.4 % threonine,

1.7 % tryptophan, 9.5 % leucine, 5.3 % isoleucine, 1.7 % methionine, 6.87 % lysine, 6.1 % phenylalanine and 6.8 % valine.

Major volatile components identified in red clover leaves were (*Z*)-3-hexenyl acetate, (*Z*)-3-hexenol and (*E*)- β -ocimene and (*Z*)- β -ocimene (Buttery et al. 1984). In red clover leaves, a total of 31 different phenolics were identified: *cis*-*trans*-phaseelic acid, *cis*-clovamide, daidzein-G, daidzein-G-M, calycosin-G, calycosin-G-M, genistein, genistein-G, genistein-G-M, pratensein, irilone, irilin B, methylorobol, methylorobol-G, methylorobol-G-M, formononetin, formononetin-G, formononetin-G-M, afrormosin-G-M, maackiain, maackiain-G-M, biochanin A, biochanin A-G-M, prunetin, texasin, texasin-G-M, quercetin-glucoside, quercetin-galactoside, quercetin-G-M, kaempferol-G and pseudobaptigenin-G-M (Saviranta et al. 2010a). The most abundant isoflavones and flavonoids were biochanin A glycoside malonate (G-M), formononetin-G-M and quercetin-G-M. Elevated ozone (mean 32.4 ppb) increased the total phenolic content of leaves and also had minor effects on the concentrations of individual compounds. Elevated ozone increased the net photosynthesis rate of red clover leaves before visible injuries by 21–23 %.

The acetone-soluble lipids of red clover leaves largely comprised galactosyl-1-glycerol (I) and L linoleate (Weenink 1961). The fatty acids of the galactolipids contained (mole%) linolenic, 95.8 %; linoleic, 1.9 %; and palmitic, 2.3 %. Oleic, stearic and palmitoleic acids were not detected. Triglycerides were not found in the acetone-soluble lipid fraction. The hexane-soluble fraction contained galactose 4.2 %, glycerol 2.4 %, nonsaponifiable matter 43.3 % and fatty acids 26.0 %, the remainder being acidic, non-fatty material. Free sterols (0.8 %), sterol esters (0.57 %), triglycerides (1.5 %), diglycerides (0.6 %) and normal hydrocarbons (0.38 %) were isolated from the acetone-soluble lipids of red clover leaves (Weenink 1962). Free and combined sterol contained β -sitosterol, and the hydrocarbons consisted of homologous odd- and even-numbered series C_{15} to C_{25} with C_{25} predominating. The diglycerides contained over 50 % of palmitic acid, whereas the sterol esters

and triglycerides contained linoleic and linolenic acids as the main components. The composition of the acetone-insoluble fraction (molar proportions) of red clover leaves comprised phosphatidycholine 37 %, phosphatidylglycerol 23 %, phosphatidylethanolamine 15 %, phosphatidylinositol 2 %, uncharacterized acidic compounds 13 % and unknown compounds 10 % (Weenink 1964). An unusual C_{14} unsaturated fatty acid was found in the phosphatidylglycerol fraction. *Trans*- Δ^3 -hexadecenoic acid (16:1') was found to occur exclusively in the phosphatidylglycerol fraction of red clover leaves (Weenink and Shorland 1964). The fatty acid composition (mol %) of phosphatidylglycerol in red clover leaves comprised 16:0 (20 %), 16:1' (40 %), 18:0 (1 %), 18:1 (7 %), 18:2 (13 %) and 18:3 (25 %) (Murata et al. 1982). In response to waterlogging, the concentrations of biochanin A and biochanin A-7-*O*-glucoside malonate, biochanin A-7-*O*-glucoside and genistein-7-*O*-glucoside in the leaves increased two- to threefold after a lag period of 3 weeks because of disturbed root nodulation (De Rijke et al. 2005). The other isoflavones detected—formononetin, formononetin-7-*O*-glucoside malonate and formononetin-7-*O*-glucoside—did not show any significant changes related to waterlogging. After restoring normal soil water conditions, the concentrations of biochanin A and its glucoside and glucoside malonate rapidly returned to the initial values, whereas the concentration of genistein-7-*O*-glucoside remained high.

Red clover leaves were found to accumulate several μ mol of phaseelic acid [2-*O*-caffeoyl-L-malate] per gram fresh weight (Sullivan and Zarnowski 2010). Their study found that phaseelic acid was likely formed by transfer of a caffeoyl moiety to malic acid, although the existence of a second $C_3'H$ capable of hydroxylating p-coumaroyl-malate could not be definitively excluded. They identified coumarate 3'-hydroxylase (CYP98A44), a cytochrome P450 which was capable of hydroxylating p-coumaroyl-shikimate but not p-coumaroyl-malate in the biosynthesis of phaseelic acid. The gene for cytochrome P450 $C_3'H$ (CYP98A44) was cloned from red clover.

Root Phytochemicals

Formononetin and the new isoflavonoid glycosides formononetin-7-*O*- β -D-galactopyranoside and inermine-3-*O*- β -D-galactopyranoside were isolated from *Trifolium pratense* roots (Drenin et al. 2008). The following volatile compounds were identified from red clover roots: butyl acetate, E-2-hexenal, α -pinene, benzaldehyde, 6-methyl-5-hepten-2-one, limonene, acetophenone, methyl benzoate, nonanal, octanoic acid and decanal (Tapia et al. 2007). The results showed that the clover root borer (*Hylastinus obscurus*) was attracted to root volatiles of 1.5-year-old extracts but not to those from 2.5-year-old extracts. A 10 μ g dose of methyl benzoate and E-2-hexenal attracted the insect, whereas the same dose of limonene repelled the red clover borer. The following volatiles and free fatty acids were detected in the dichloromethane extract of 9-month-old red clover roots: 1-nonene, 3-octanol, 2-pentyl furan, benzyl alcohol, limonene, maltol, benzoic acid, *o*-acetyl-*p*-cresol, eugenol, caryophyllene oxide, pentadecanal, lauric acid, palmitic acid, oleic acid and stearic acid (Manosalva et al. 2011). The four long-chain free fatty acids lauric, palmitic, oleic and stearic acids were found to be main components in the extract. Further studies on the response of clover root borer to volatiles emitted from red clover roots afforded the identification of ethanol, E-2-hexenal, hexanal, 3-octanone, limonene and α -pinene (Palma et al. 2012). For females, ethanol and E-2-hexenal were attractive at one or more of the tested doses, while hexanal, 3-octanone, R-limonene and S-limonene were repellent at one or more of the tested doses. In a much earlier study, of 15 root compounds, 10 were attractive to the borer clover root borer (*Hylastinus obscurus*) (Kamm and Buttery 1984). None of the attractive compounds were competitive with crude extracts of diseased roots when tested individually. Certain combinations of ethyl laurate, ethyl benzoate, methyl salicylate, eugenol, hexadecanal and chavicol were competitive with crude extracts of diseased root in laboratory tests. Adult borers were not attracted to individual compounds or mixtures in preliminary field tests.

A total of 28 phenolic compounds were tentatively identified in red clover roots (Saviranta et al. 2010b). The most abundant phenolics in pot-grown roots were formononetin glycoside malonate (G-M) (1.51–4.26 mg/g), formononetin (2.21–3.57 mg/g) and biochanin A (1.73–2.17 mg/g), whereas field-grown roots were rich in formononetin-G-M (3.90–4.27 mg/g), maackiain-G-M (2.35–3.02 mg/g) and pseudobaptigenin-G-M (1.80–2.58 mg/g). Concentrations were affected by the growth stage and ozone exposure slightly affected the total phenolic content in roots and also had minor effects on individual compounds. The isoflavonoids formononetin, formononetin-7-*O*- β -D-galactopyranoside and inermine-3-*O*- β -D-galactopyranoside were isolated from the roots (Drenin et al. 2011).

Flower/Seed Phytochemicals

T. pratense seeds were found to contain quercetin, soyasaponin I, 22-*O*-glucoside and 22-*O*-diglucoside of soyasaponin I and astragaloside VIII (Oleszek and Stochmal 2002).

More than 50 compounds were identified in the essential oil samples of red and white Austrian clover flowers (Buchbauer et al. 1996). The main constituents (concentration >2 %) were maltol (8.2 %), linalool (4.2 %), 1-phenylethyl alcohol (3.2 %), phenol (2.9 %), phenylethyl acetate (2.7 %), acetophenone (2.4 %), and (*Z*)-3-hexenyl acetate (2.2 %) for red clover flowers and maltol (5.3 %), linalool (3.8 %), phenol (3.6 %), phenylethyl acetate (3.3 %) and 2-phenylethyl alcohol (2.8 %) for white clover flowers. Major volatile components identified in red clover flowers were acetophenone, methyl cinnamate and 1-phenylethanol (Buttery et al. 1984). Major volatile components identified in red clover seed pods were (*E*)- β -ocimene and (*Z*)- β -ocimene, longifolene and an unidentified sesquiterpene hydrocarbon (Buttery et al. 1984).

Twenty flavonoid glycoside malonates were detected in red clover flower extract (Lin et al. 2000). Eight were identified as genistin 6''-*O*-malonate (39), formononetin 7-*O*- β -D-glucoside 6''-*O*-malonate (40), biochanin A 7-*O*- β -D-glucoside 6''-*O*-malonate (41), trifoside

6''-O-malonate (42), irilone 4'-O-β-D-glucoside 6''-O-malonate (43), pratensein 7-O-β-D-glucoside 6''-O-malonate (44), isoquercitrin 6''-O-malonate (45), and 3-methylquercetin 7-O-β-D-glucoside 6''-O-malonate (46). About 15 other flavonoids and clovamide were present in this extract. Floral procyanidins of red clover comprised a range of oligomeric procyanidin ions (DP of 2–11) (Sivakumaran et al. 2004). The thiolysis reaction products indicated a mean degree of polymerization (mDP) of 9.3 with epicatechin (81 %) as the abundant flavan-3-ol extension unit and the terminating units dominated by catechin (95 %).

Antioxidant Activity

All *T. pratense* leaf extracts especially water and ethyl acetate extracts showed good antioxidant activity when evaluated using DPPH, hydroxyl, superoxide anion and nitric oxide radical scavenging and lipid peroxidation assays (Kaurinovic et al. 2012). In the DPPH assay, the IC₅₀ (50 % of reduction) values in µg/ml were as follows: 17.47 µg for H₂O (water), 17.81 µg for EtOAc (ethyl acetate), 20.36 µg for Et₂O (diethyl ether), 29.47 µg for n-BuOH (n-butanol), and 34.19 µg for CHCl₃ (chloroform) extract compared to synthetic antioxidants tert-butylated hydroxytoluene (BHT) and butylated hydroxyanisole (BHA) BHT (14.31 µg) and BHA (11.08 µg). In scavenging of superoxide and NO radicals, H₂O extract demonstrated highest activity but was lower than that of BHT and BHA. The lowest antioxidant activity was expressed by the CHCl₃ (IC₅₀=92.37 µg/ml for superoxide and IC₅₀=58.46 µg/ml for NO radical) extract. Good antioxidant scavenging of OH radical was shown by the H₂O (IC₅₀=18.44 µg/ml) and EtOAc (IC₅₀=19.79 µg/ml) extracts, which showed higher ability than BHT and BHA (IC₅₀=22.17 µg/ml). The worst effect on the neutralization of all the radicals studied in-vitro was shown by the n-BuOH extract. In lipid peroxidation suppressing activity, H₂O extract exhibited the highest activity followed by EtOAc extract. In in-vivo experiments in the liver homogenate and blood of mice after their treatment with extracts of *T. pratense* leaves, or in combination with CCl₄,

all the extracts decreased the GSH (reduced glutathione) and GSHPx (glutathione peroxidase) content compared with control. Treatment with the EtOAc extract yielded an increase in GSHR (glutathione reductase) activity, whereas the other four extracts caused a statistically significant decrease of this enzyme, which was in agreement with the action of this enzyme on GSH. Only H₂O extract produced a statistically significant increase in Px (peroxidase) activity. The LPx (lipid peroxidation activity) was lowered in the liver homogenate of animals treated with all extracts. The CAT (catalase) increased in the treatments with EtOAc, n-BuOH and H₂O extracts, but the other extracts caused no essential changes of CAT with respect to control. A statistically significant decrease of XOD (xanthine oxidase) activity was observed in the experimental animals treated with last three extracts (EtOAc, n-BuOH and especially H₂O). The amount of total phenolics in *T. pratense* leaf extracts ranged from 0.16 mg GAE/g d.e. (CHCl₃ extract) to 0.43 mg GAE/g d.e. (EtOAc extract) (Kaurinovic et al. 2012). A significant amount of these compounds were observed in the H₂O extract (0.34 mg GAE/g d.e.). Comparatively lower amount of total flavonoids was determined in the n-BuOH extracts, while the smallest quantity of was found in the Et₂O and CHCl₃ extracts. Quercetin glycosides and flavonoids (kaempferol-3-O-glucoside, quercetin-3-O-glucoside, luteolin-7-O-glucoside and apigenin-7-O-glucoside) were detected in EtOAc extract, while the presence of phenolic acids (such as caffeic acid) and flavonoids (luteolin, apigenin, naringenin and kaempferol) was confirmed in the H₂O extract. Additionally, two phytoestrogens (daidzein and genistein) were detected in the H₂O extract. The results suggested that the water and ethyl acetate leaf extracts afforded the best in-vitro and in-vivo antioxidant activity in protecting against carbon tetrachloride toxicity.

Anticancer Activity

Slater et al. (2002) found that in mice fed a diet supplemented with red clover isoflavones, the prostatic epithelium displayed a significant increase in the production of oestrogen receptor

beta and the adhesion protein E-cadherin but a decrease in transforming growth factor beta 1. These proteins were oestrogenically induced markers of proliferation, maintenance of histological architecture, preservation of cell phenotype and reduction of the potential for neoplastic and metastatic transformation. Their study suggested that red clover isoflavones presented a nontoxic dietary treatment for prostatic hyperplasia and a reduction in the potential for neoplastic transformation. Jarred et al. (2003) found that red clover-derived dietary isoflavones (RC) suppressed prostate growth in-vivo in the aromatase knockout (ArKO) mouse exhibiting lifelong elevation of androgens leading to prostate enlargement. Following 28 days of RC diet, ArKO ventral prostate (VP), anterior prostate, and seminal vesicle weights were reduced to wild-type mouse weights, although testis and body weights remained unaltered. Stereological analysis of VPs revealed a reduction in all components of the tissue, particularly the lumen. The RC diet reduced ArKO serum testosterone and dihydrotestosterone to WT levels. In comparison to castration and oestrogen administration, the dietary isoflavones were shown to be antiandrogenic rather than weakly oestrogenic. Engelhardt and Riedl (2008) found that 1-year treatment of 20 men (mean age 65 years) with isoflavone extract from red clover elicited a significant reduction of 33 % in prostate-specific antigen (PSA) level and a slight decrease in prostate volume. Sexual hormone levels (total testosterone, oestrogen, luteotropic hormone, follicle-stimulating hormone and dehydroepiandrosterone sulphate) did not change throughout the study. However, a significant increase in all three liver transaminases after 3 months was recorded. The International Prostate Symptom Score showed a mean value of 7.9 at baseline and 6.68 after 12 months. Sexual function was not influenced by the treatment. Daily oral administration of 60 mg of an isoflavone extract was well tolerated and caused no side effects. In in-vitro studies, red clover isoflavones at 25.0 µg/ml significantly inhibited the proliferation by 18.86 % and promoted the apoptosis of human benign prostatic hyperplasia (BPH) stromal

cells by 18.54 % compared to negative and blank control (Chen et al. 2010).

Studies by Ye et al. (2012) suggested that higher concentrations of formononetin inhibited the proliferation of prostate cancer cells (LNCaP and PC-3), while the most striking effect was observed in LNCaP cells. They further found that formononetin inactivated extracellular signal-regulated kinase1/kinase2 (ERK1/ERK2) mitogen-activated protein kinase (MAPK) signalling pathway in a dose-dependent manner, which resulted in increased the expression levels of BCL2-associated X (Bax) mRNA and protein, and induced apoptosis in LNCaP cells.

A series of cases in which *Trifolium pratense* was used in breast disease with hyperoestrogenic symptoms was reported by Parvu (2004). Several patients with cystic mastosis and breast cancer appeared to do well. In a 3-year randomized, double-blind, placebo-controlled pilot trial of healthy women aged 35–70 years with a family history of breast cancer, treatment with red clover isoflavones did not adversely affect breast density, skeletal strength or cardiovascular status (Powles et al. 2008). In postmenopausal women, endometrial status was not adversely affected. The adverse event profile was similar between red clover isoflavones, and placebo and endocrine status did not differ. Treatment with red clover isoflavones was found to be safe and well tolerated in healthy women. The principal isoflavones genistein and daidzein contained in red clover extracts acted as weak oestrogenic compounds when administered alone in ER positive breast cancer cells (Mannella et al. 2012). However, when provided in association with physiological amounts of estradiol, red clover extract acted as oestrogen antagonist on remodelling of actin cytoskeleton. The results indicated that isoflavones contained in red clover acted as natural selective oestrogen receptor modulators in the presence of physiological amounts of oestrogens.

The 95 % ethyl alcohol extract of one of red clover significantly inhibited the metabolism of [3H]benzo(a)pyrene [B(a)P] and decreased the level of binding of B(a)P to DNA by 30–40 % (Cassady et al. 1988). Its active isoflavone

component, biochanin A, also decreased the metabolism of B(a)P by 54 % in comparison to control cultures and decreased B(a)P-DNA binding by 37–50 % at a dose of 25 µg/ml indicating its potential as a chemopreventive agent. A separate study showed that biochanin A was able to decrease dimethylbenz[a]anthracene (DMBA)-induced DNA damage in MCF-7 cells by curbing cytochrome P450 (CYP) 1 enzymes through the interference of XRE-dependent transactivation (Chan et al. 2003). Enzyme kinetic studies also indicated that biochanin A inhibited both CYP1A1 and CYP1B1 enzymes. The study illustrated that the red clover isoflavone could protect against polycyclic aromatic hydrocarbon-induced DNA damage.

Red clover isoflavones, namely, daidzein, genistein, formononetin and biochanin, were found to inhibit COX enzyme activity in both the murine macrophage cell line RAW 264.7 and human monocytes (Lam et al. 2004). Within the range of 1–40 µM in RAW 264.7 cells and 10–100 µM in human monocytes, isoflavones were able to reduce significantly the synthesis of prostaglandin E2 and/or thromboxane B2 indicating COX inhibition. They concluded that it was possible that the lower rates of some cancers in populations with a high intake of dietary isoflavones could be linked to their inhibition of COX activity. Another study found that biochanin A and/or formononetin, predominant isoflavones from red clover, may exert anticarcinogenic effects directly by acting as competitive substrates for human cytochrome CYP1B1 or indirectly through their metabolites daidzein and genistein, which inhibited CYP1B1 (Roberts et al. 2004). Three of the biochanin A metabolites (5,7,3'-trihydroxy-4'-methoxyisoflavone, 5,7,8-trihydroxy-4'-methoxyisoflavone and 5,6,7-trihydroxy-4'-methoxyisoflavone) were characterized. Daidzein ($K_i = 3.7$ µM) exhibited competitive inhibition of CYP1B1 7-ethoxyresorufin *O*-deethylase activity, and genistein ($K_i = 1.9$ µM) exhibited mixed inhibition. In-vitro studies in MCF-7 breast carcinoma cells showed that biochanin A, the red clover isoflavone, may act as an antagonist/agonist to bind on the aryl hydrocarbon receptor that

mediates the carcinogen activation pathway (Han et al. 2006). Treating the cells with biochanin A alone caused the accumulation of CYP1A1 mRNA and an increase in CYP1A1-specific 7-ethoxyresorufin *O*-deethylase (EROD) activity in a dose-dependent manner. A concomitant treatment with 7,12-dimethylbenz[a]anthracene (DMBA) and biochanin A markedly reduced the DMBA-inducible EROD activity and CYP1A1 mRNA level. Biochanin A competitively inhibited the metabolic activation of DMBA, as measured by the formation of the DMBA-DNA adducts. In MCF-7 breast cancer cells stably transfected with CYP19, biochanin A inhibited aromatase activity and hampered cell growth attributing to the enzyme activity (Wang et al. 2008). Additionally, biochanin A significantly reduced CYP19 mRNA abundance in the oestrogen receptor-negative breast cancer cells SK-BR-3. Luciferase reporter gene assays also revealed that biochanin A could repress the transcriptional control dictated by the promoter regulation. The present study illustrated that biochanin A inhibited CYP19 and aromatase activities and gene expression.

Estrogenic Activity/Menopause Management

In-Vitro Studies

Methanol extracts of red clover and hops showed significant competitive binding to oestrogen receptors alpha (ER alpha) and beta (ER beta) (Liu et al. 2001). With cultured Ishikawa (endometrial) cells, red clover and hops exhibited oestrogenic activity as indicated by induction of alkaline phosphatase (AP) activity and upregulation of progesterone receptor (PR) mRNA. Genistein was the most active component of red clover and was found to be the most effective of four red clover isoflavones tested in the above in-vitro assays. Another study showed that a preformulated (i.e. no excipients present) red clover extracts an EC_{50} of 2.0–2.2 µg/ml in the AP (alkaline phosphatase) oestrogenicity assay and IC_{50} s of 18.4–32.6 µg/ml and 1.9–3.4 µg/ml in the recombinant human oestrogen receptors $ER\alpha$ and $ER\beta$ binding assays, respectively (Booth

et al. 2006). The preformulated extract was composed of 35.54 % isoflavones, 1.11 % flavonoids, 0.06 % pterocarpan, ≤ 0.03 % coumarins and ≤ 0.03 % tyramine. Daidzein, genistein, formononetin, biochanin A, coumestrol and naringenin were oestrogenic in the AP assay, and all of these, except formononetin, bound to one or both ERs. Red clover extracts were found to activate NO synthesis in endothelial cells by recruiting transcriptional pathways mediated by a recruitment of oestrogen receptor-beta but were not capable of inducing rapid NO synthesis through nongenomic mechanisms (Simoncini et al. 2005). They showed that red clover-derived isoflavones synergized with 17 β -estradiol in increasing endothelial nitric oxide synthase activity and expression, therefore being devoid of antiestrogenic effects in human endothelial cells.

Red clover extract and its active isoflavone components were found to have oestrogenic activity. The IC₅₀ values for the oestrogen receptor alpha and beta binding assays were 18.0 and 2.0 μ g/ml, respectively, for the red clover extract (Overk et al. 2005). The extract and genistein activated the oestrogen response element (ERE) in Ishikawa cells while the extract, biochanin A and genistein significantly induced ERE-luciferase expression in MCF-7 cells. The red clover extract upregulated progesterone receptor (PR) mRNA in the Ishikawa cell line. In the MCF-7 cell line, PR mRNA was significantly upregulated by the extracts biochanin A and genistein. The extract had an EC₅₀ value of 1.9 μ g/ml in the alkaline phosphatase induction assay. The results suggested that red clover could be attractive for the development as herbal dietary supplements to alleviate menopause-associated symptoms.

Red clover extracts were reported to contain a variety of isoflavones, with affinity towards oestrogen receptor alpha (ERalpha), oestrogen receptor beta (ERbeta), androgen receptor (AR) and progesterone receptor (PR) (Pfischer et al. 2008). Testing of biochanin A, formononetin, genistein, daidzein, dihydrobiochanin A, dihydroformononetin, dihydrogenistein, dihydrodaidzein, 3'-hydroxygenistein, 6-hydroxydaidzein, 6-hydroxydesmethylangolensin, equol,

O-desmethylangolensin, angolensin and *p*-ethylphenol for their transactivation potential towards ERalpha, AR and PR in yeast revealed that the compounds showed only weak binding affinity to AR and PR, with IC₅₀ values being greater (i.e. lesser affinity) than 10⁻⁵ M for the respective receptor. Mueller and Jungbauer (2008) found that red clover extracts and its major components, genistein and biochanin A, and especially several main metabolites exerted significant PPAR- γ ligand binding and transactivational activity. 6-Hydroxydaidzein exerted a more than 100-fold higher binding affinity than its precursor daidzein. The maximal transactivational activity of 6-hydroxydaidzein and 3'-hydroxygenistein exceeded even that of rosiglitazone, a known PPAR- γ agonist. Equol and *O*-desmethylangolensin showed an approximately fivefold higher binding affinity and, in the case of *O*-desmethylangolensin, a fourfold higher PPAR- γ agonistic activity than the precursor. Red clover extract, which is currently used for treating menopausal disorders, could be simultaneously used for ameliorating the metabolic syndrome.

Trifolium pratense, a common herb used for the relief of menopausal symptoms, was found to possess opiate activity (Nissan et al. 2007). The extract was found to have affinity at the delta-opiate receptor. Given the essential role of the opioid system in regulating temperature, mood, and hormonal levels and actions, this may explain in part the beneficial effect of red clover in alleviating menopausal symptoms.

Animal Studies

Administration of red clover extract containing 15 % isoflavones [250, 500 and 750 mg/(kg \times d)] to ovariectomized 50-day-old Sprague-Dawley rats, for 21 days, produced a dose-dependent increase in uterine weight and differentiated vaginal cells at the two higher doses, but it did not stimulate cell proliferation in the mammary glands (Burdette et al. 2002). Neither antiestrogenic nor additive oestrogenic properties were observed in any of the tissues studied. The results suggested red clover extract to be weakly oestrogenic in the ovariectomized rat model.

Rimoldi et al. (2007) found in rats treated with either of the 17 β -estradiol E(2) or high dose of genistein (isoflavone from red clover) exhibited increased uterine weight, and histological analysis showed oestrogen-induced features in the uteri. In vaginae, either E(2) dose or genistein high dose induced hyperplastic epithelium compared with the atrophic controls. In the mammary gland, E(2) (either dose) or genistein increased proliferation and PR expression. Serum levels of luteinizing hormone were decreased by E(2) (both doses) but not by genistein.

In ovariectomized uterotrophic adult rats, Overk et al. (2008) found that *Humulus lupulus* extract and a 30 % isoflavone extract of *T. pratense* did not have an oestrogenic effect on the uterus, and none of the secondary outcome measures were positive; but 8-prenylnaringenin (8-PN) from *H. lupulus* at equivalent doses to those previously used in humans did have an effect and may therefore have a deleterious effect in women. In another study, oral administration of formononetin from red clover to ovariectomized mice increased the uterine weight of the mice significantly as well as the content of SOD, GSH-Px, CAT and reduced MDA (Mu et al. 2009). The results indicated that formononetin had obvious antioxidant effects and oestrogenic effect, and the oestrogenic effect was not dosage related. Adaikan et al. (2009) found that supplementing red clover extract daily for 12 weeks or daidzein isoflavone to rabbits with experimentally induced menopause led to significant improvements in bone density, tissue integrity and vaginal blood flow with minimal effect on uterine weight and may therefore be a viable alternative to conventional regimens using synthetic oestrogens.

Supplementation of rat chow diet with red clover elicited oestrogen-like biological effects in pregnant rats (Yatkin and Daglioglu 2011). Relative uterus, ovary weights, number of uterine glands and luminal epithelium heights in the experimental groups were increased compared to control. However, there were no statistically significant changes detected in the immunostaining intensity of ER α and PR between the groups.

Clinical Studies

In a study of 17 menopausal women, isoflavones from red clover were found to significantly improve systemic arterial compliance which diminishes with menopause, but not plasma lipids (Nestel et al. 1999). As diminished compliance leads to systolic hypertension and may increase left ventricular work, the findings indicated a potential new therapeutic approach for improved cardiovascular function after menopause.

In a three-period, randomized, double blind, placebo trial of 66 postmenopausal women with plasma cholesterol levels between 5.0 and 9.0 mmol/l, dietary supplementation of isoflavone phytoestrogens from red clover in the proportions and quantities studied did not significantly alter total plasma cholesterol, LDL cholesterol, HDL cholesterol or plasma triglyceride levels (Howes et al. 2000). However, inverse correlations were found between urinary genistein excretion and plasma triglyceride levels and between urinary O-DMA excretion (an isoflavone metabolite) and plasma triglyceride levels in subjects receiving one isoflavone tablet, suggesting a weak relationship between isoflavone intake and plasma triglycerides which may be influenced by individual differences in isoflavone absorption or metabolism. In another 90-day randomized, double-blind, placebo-controlled study wherein 53 postmenopausal women (88.3 %) completed the trial, red clover isoflavone supplementation significantly decreased menopausal symptoms and had a positive effect on vaginal cytology and triglyceride levels (Hidalgo et al. 2005). Mean total cholesterol, low-density lipoprotein-cholesterol and triglyceride levels also decreased; however, only the latter was significantly lower compared with placebo.

In a randomized, four-arm, double-blind clinical trial of standardized black cohosh, red clover and placebo, and 0.625 mg conjugated equine oestrogens plus 2.5 mg medroxyprogesterone acetate (CEE/MPA) of menopausal women, compared with placebo (63 %), black cohosh (34 %) and red clover (57 %), did not reduce the number of vasomotor symptoms. Only CEE/MPA (94 %) differed significantly from placebo (Geller et al. 2009). Safety monitoring

indicated that chemically and biologically standardized extracts of black cohosh and red clover were safe during daily administration for 12 months. In a double-blind, randomized, parallel study for four menstrual cycles involving 23 premenopausal women, supplementation of purified red clover isoflavone (86 mg/day) tablets elicited no effect on serum homocysteine or folate in premenopausal women (Samman et al. 2009). In a phase II randomized, double-blinded, placebo-controlled safety and efficacy trial of two botanicals, black cohosh and red clover, for the management of vasomotor symptoms in healthy perimenopausal and postmenopausal women Geller et al. (2009) found that compared with placebo, black cohosh and red clover did not reduce the number of vasomotor symptoms. Safety monitoring indicated that chemically and biologically standardized extracts of black cohosh and red clover were safe during daily administration for 12 months.

In a randomized, crossover, placebo clinical trial involving 109 postmenopausal women aged 40 or more for a total of 187 days with a 7-day washout period, treatment with isoflavones derived from red clover extracts was found to be effective in reducing depressive and anxiety symptoms among postmenopausal women (Lipovac et al. 2010). This effect was equivalent to a 76.9 % reduction in the total Hospital Anxiety and Depression Scale (HADS) score (76 % for anxiety and 78.3 % for depression) and an 80.6 % reduction in the total Zung Self-Rating Depression Scale (SDS) score. They also found that red clover isoflavone supplementation was more effective than placebo in reducing daily vasomotor frequency and overall menopausal intensity in postmenopausal women (Lipovac et al. 2012). Studies by del Giorno et al. (2010) found that a 12-month treatment of women aged 45–65 years with menopausal symptoms, with a daily dose of 40 mg *Trifolium pratense*, did not yield a significant improvement in menopausal symptoms and sexual satisfaction.

Review Studies

The report on the role of isoflavones in menopausal health by the North American Menopause

Society (NAMS) (2000) found that the data were inconclusive regarding whether the observed health effects in humans were attributable to isoflavones alone or to isoflavones plus other components in whole foods. The most convincing health effects had been attributed to the actions of isoflavones on lipids as studies had associated isoflavones with statistically significant reductions in low-density lipoproteins and triglycerides as well as increases in high-density lipoproteins. Although some data appeared to support the efficacy of isoflavones in reducing the incidence and severity of hot flashes, many studies had not found any difference between the isoflavone recipients and the controls. Inadequate data existed to evaluate the effect of isoflavones on breast and other female-related cancers, bone mass and vaginal dryness.

In their review, Fugh-Berman and Kronenberg (2001) stated that studies showed that red clover extracts to date have not clearly demonstrated benefits for menopausal symptoms as the potential oestrogenic effects on breast and endometrium had not been adequately assessed. However, study examining the effect of red clover on arterial compliance found a significant beneficial effect on arterial compliance. A review of randomized, controlled trials of peri- or postmenopausal women reported that isoflavones found in soy foods and red clover appeared to have a small but positive health effect on plasma lipid concentrations, bone mass density and cognitive abilities (Geller and Studee 2006). The review and meta-analysis conducted by Coon et al. (2007) found evidence of a marginally significant effect of *T. pratense* isoflavones for treating hot flushes in menopausal women.

Antihypercholesterolaemic Antihyperlipidaemic Activity

Animal Studies

Asgary et al. (2007) found that dietary use of red clover (RC) in hyperlipidaemic rabbits significantly decreased C-reactive protein (CRP), triglyceride (TG), total cholesterol and LDL cholesterol (LDL-C) whereas, HDL cholesterol

(HDL-C) was significantly increased in those animals. Fatty streak formation was also significantly lower in aorta and left and right coronary arteries in the same animals due to use of dietary RC supplementation. The findings suggested that dietary RC may reduce cardiovascular risk factors. Treatment of red clover extract 450 mg/kg/day for 4 days to ovariectomized rats significantly reduced plasma LDL concentrations, whereas triglycerides increased and plasma HDL and total cholesterol remained unchanged (Pakalapati et al. 2009). The extract influenced the transcript levels of many novel oestrogen and non-oestrogen-responsive genes as well as other regulatory genes. Quantitative reverse transcription analysis with real-time PCR confirmed that red clover extract regulates genes involved in lipid metabolism and antioxidation mechanisms. The scientists concluded that isoflavone-rich red clover extract mediated numerous genomic and nongenomic effects, which influence besides the lipid metabolism a broad range of cellular functions, including metabolic actions, cell cycle regulation and antioxidant activity.

Red clover extract exerted a significant effect on lowering of blood glucose levels and serum triglyceride, serum total cholesterol, liver triglyceride and liver cholesterol levels of type 2 diabetic db/db mice compared to those of the untreated diabetic mice (Qiu et al. 2012a). The significant improvement in glucose and lipid homeostasis in db/db diabetic mice was partly attributed to activation of hepatic peroxisome proliferator-activated receptor (PPAR) gamma and suppression of hepatic fatty acid synthase. In another study they found that red clover extract had no significant effect on lowering the blood glucose levels of streptozotocin (STZ)-induced diabetic mice (Qiu et al. 2012c). Similarly, its constituents biochanin A and formononetin exerted no hypoglycaemic effect. However, the serum triglycerides, total cholesterol and low-density lipoprotein-cholesterol levels for STZ-diabetic mice receiving red clover extract or biochanin A or formononetin were significantly lower than that of untreated STZ-diabetic mice. The antihyperlipidaemic effects of red clover extract, biochanin A and formononetin were found to be partly due to activation of

hepatic peroxisome proliferator-activated receptor (PPAR) alpha.

Clinical Studies

In a double-blind, randomized, parallel study of healthy premenopausal women, supplementation of purified isoflavones, derived from red clover, resulted in no significant effects on total cholesterol, LDL and HDL cholesterol, HDL subfractions, triacylglycerol, lipoprotein(a), glucose or insulin concentrations (Blakesmith et al. 2003). Supplementation with isoflavones resulted in a 15-fold increase in urinary isoflavone excretion. The results indicated that purified isoflavones derived from red clover had no effect on cholesterol homeostasis or insulin resistance in premenopausal women, a group with low risk of coronary heart disease.

In a 6-week, randomized, placebo-controlled, double-blind, crossover design trial of 46 middle-aged men and 34 postmenopausal women, isolated isoflavones from red clover enriched in biochanin (genistein precursor) but not in formononetin (daidzein precursor) lowered LDL-C in men (Nestel et al. 2004). No other lipid was affected and women failed to respond significantly to treatment. In another randomized, placebo-controlled crossover study with a minimum 2-month washout period involving healthy pre- ($n=16$) and postmenopausal ($n=7$) women, 1-month supplementation with red clover isoflavones was found to have a positive effect on HDL cholesterol, but at most a small effect on insulin-like growth factor status in premenopausal and no effect in postmenopausal subjects (Campbell et al. 2004). In another randomized double-blind, placebo-controlled study of 177 perimenopausal 49–65 year-old women, supplementation of red clover-derived isoflavones gave no differences between treatments for changes from baseline to 12 months in total cholesterol, LDL cholesterol, triglycerides, HDL cholesterol, systolic and diastolic blood pressures, fibrinogen and plasminogen activator inhibitor type 1 (PAI-1) (Atkinson et al. 2004). Interactions between treatment and menopausal status were significant for changes in triglycerides and PAI-1, and changes were significant among perimenopausal women. Interactions between apolipoprotein E (apoE)

genotype and treatment tended to be significant for changes in total and LDL cholesterol, and differences between treatments were significant in E2/E3 women. This study suggested that isoflavones alone were not responsible for the well-documented effects.

In a 90-day crossover, randomized placebo study of equal design wherein 53 postmenopausal women with increased body mass index (88.3 %) completed the trial, *Trifolium pratense*-derived isoflavone supplementation had a positive effect on the lipid profile as evidenced by a significant decrease in TC, LDL-C and lipoprotein A levels (Chedraui et al. 2008). In another clinical study of 40 healthy postmenopausal women with an average age of 56 years, red clover phytoestrogen supplementation was found to have favourable metabolic effects on serum lipids (Tercic et al. 2009). Both total serum cholesterol and low-density lipoprotein (LDL) cholesterol levels, as well as triglyceride levels, were decreased significantly in the group receiving phytoestrogens. However, high-density lipoprotein (HDL) cholesterol showed a significant increase. Furthermore, red clover phytoestrogens had no side effects and could be considered safe.

Antimicrobial Activity

Both clover extracts and its isoflanoid component biochanin A inhibited the growth of *Clostridium sticklandii* in broth culture, but formononetin had no effect (Flythe and Kagan 2010). This Gram-positive, hyperammonia-producing bacterium (HAB) is largely responsible for amino acid deamination in the rumen. Ruminal proteolysis and subsequent amino acid degradation represent considerable economic loss in ruminant production. Biochanin A inhibited the HAB bacterium growth at a very low concentration of 8 nmol. (Kagan and Flythe 2012).

Neuroprotective Activity

Studies showed that five isoflavones (formononetin, daidzein, pratensein, calycosin and irilone) from

Trifolium pratense attenuated lipopolysaccharide (LPS)-induced decrease in dopamine uptake and the number of dopaminergic neurons in a dose-dependent manner in rat mesencephalic neuron–glia cultures (Chen et al. 2008). They also significantly inhibited LPS-induced activation of microglia and production of tumour necrosis factor- α , nitric oxide and superoxide in mesencephalic neuron–glia cultures and microglia-enriched cultures. The protective potency of five isoflavones ranked as follows: pratensein > daidzein > calycosin > formononetin > irilone. Another study showed that pretreatment of human cortical cell line HCN 1-A with 0.5, 1 and 2 $\mu\text{g/ml}$ isoflavone-enriched fraction from red clover prevented the morphological disruption caused by glutamate toxicity (Occhiuto et al. 2008). In contrast exposure of HCN 1-A cell cultures to glutamate resulted in concentration-dependent damage in neuronal membrane damage and decreases in neuron viability. The results indicated that the isoflavone fraction had a neuroprotective effect in human cortical neurons and that this effect might have resulted from antioxidant and oestrogenic actions. In another study, they reported that a 24-hour pretreatment of HCN 1-A with 0.5, 1 and 2 $\mu\text{g/ml}$ isoflavones (genistein, daidzein, biochanin A and formononetin from *Trifolium pratense*) extract significantly increased cell survival and significantly prevented the morphological disruption caused by hydrogen peroxide (Occhiuto et al. 2009). Exposure of HCN 1-A cell cultures to hydrogen peroxide resulted in a concentration-dependent decrease in neuron viability. The neuroprotective effect of isoflavones extract was partly attributed to their antioxidant activity. Further, the results indicated that although isoflavones extract exerted a neuroprotective effect, they did not promote cortical neuron process outgrowth.

A recent study found that exposure of neuronal PC12 cells to 10 mM L-glutamate significantly increased cell viability loss and apoptosis, whereas pretreatment with various concentrations of biochanin A, from *T. pratense*, attenuated the cytotoxic effects of L-glutamate (Tan et al. 2013). The pretreatment elicited not only decreases in the release of lactate dehydrogenase, the number of apoptotic cells, and the activity of caspase-3

but also an increase in the total glutathione level in the L-glutamate-treated PC12 cells. These results indicated that biochanin A may be able to exert neuroprotective effects against L-glutamate-induced cytotoxicity. Pretreatment of primary-cultured cortical neurons with formononetin (10 μ M) for 12 hours significantly attenuated the cell loss induced by N-methyl-D-aspartate (NMDA) exposure (Tian et al. 2013). It was found that treatment of formononetin attenuated the number of apoptotic cells, especially the early phase apoptotic cells, induced by NMDA exposure. Formononetin regulated the expression of apoptosis-related proteins by increasing the levels of Bcl-2 and pro-caspase-3 and decreasing the levels of Bax and caspase-3. The findings demonstrated that formononetin was capable of protecting neurons from NMDA-evoked excitotoxic injury and may have potential to be used in the clinical treatment of neurodegenerative disorders in central nervous system.

Antiinflammatory Activity

Yang et al. (2008) found that red clover extract exhibited potent antiinflammatory effects on mice by inhibiting the activation and proliferation of mouse lymphocytes and by inhibiting the excessive production of inflammatory mediators (NO, CD69, CD25, CD71) by mouse macrophages in a dose-dependent manner. Studies showed that red clover extracts acted as antiinflammatory and antiatherogenic agents on human endothelial cells by reducing the expression of the leukocyte adhesion molecules ICAM-1 and VCAM-1 induced bacterial lipopolysaccharide (Simoncini et al. 2008). It was concluded that red clover extracts may induce beneficial actions on human vessels. Qiu et al. (2012b) showed that a total amount of 10 μ mol/l of biochanin A or genistein significantly suppressed the secretion of tumour necrosis factor α (TNF α) and interleukin-6 (IL-6) in LPS-induced RAW264.7 cells, whereas another two isoflavones, formononetin and daidzein, only significantly suppressed the secretion of interleukin IL-6. Their antiinflammatory efficiencies were not in correspondence with

their peroxisome proliferator-activated receptors PPAR α/γ agonist activities.

Red clover extract was found to be a source for substances that activated peroxisome proliferator-activated receptor (PPAR) alpha and ameliorated the cytokine secretion profile of lipopolysaccharide-stimulated macrophages (Mueller et al. 2010). Red clover extract and its isoflavones genistein and biochanin A were found to be moderate PPAR α activators. Daidzein only slightly activated PPAR α , but its metabolite 6-hydroxydaidzein exerted a much higher PPAR α activity. Similarly, the metabolite 3'-hydroxygenistein afforded higher activation efficiency than its precursor, genistein. In lipopolysaccharide-stimulated macrophages, red clover extract and its isoflavone compounds reduced the secretion of proinflammatory cytokines, interleukin-6 and tumour necrosis factor-alpha, increased the secretion of the antiinflammatory interleukin-10 and/or reduced the expression of nuclear factor-kappaB, inducible nitric oxide synthase and/or cyclooxygenase 2. Tumour necrosis factor alpha production was most efficiently reduced by biochanin A and genistein. Interleukin-6 levels were most markedly reduced by genistein and equol. The results suggested red clover extract to be a putative candidate for preventing atherosclerosis and, thus, cardiovascular disease.

Spasmolytic Activity

Crude red clover extract (Trinovin) inhibited electrical field stimulation induced contractions of the rat prostate across a range of frequencies with an IC₅₀ of approximately 68 μ g/ml (Brandli et al. 2010). The following isoflavones, daidzein, calycosin, formononetin, prunetin, pratensin, biochanin A and genistein, were isolated. Genistein, formononetin and biochanin A (100 μ M) from either commercial sources or isolated from red clover extract inhibited electrical field stimulation induced contractions of the isolated rat prostate. It was concluded that isoflavones contained in red clover were able to inhibit prostatic smooth muscle contractions in addition to their antiproliferative effects.

Photoprotective Activity

Studies showed that whereas the primary red clover isoflavones, daidzein, biochanin A and formononetin were inactive, 20 μ M lotions of genistein and the metabolites equol, isoequol and the related derivative dehydroequol had powerful potential to reduce the inflammatory oedema reaction and the suppression of contact hypersensitivity induced by moderate doses of solar-simulated UV radiation in hairless mice (Widyarini et al. 2001). For equol the protection was concentration dependent and 5 μ M equol markedly reduced the UV-induced inflammation but abrogated the UV-induced immunosuppression. Equol protected similarly from immunosuppression induced by the putative epidermal mediator, *cis*-urocanic acid (UCA), indicating a potential mechanism of action involving inactivation of this UV photoproduct. They also found that lotions containing equol, unlike topical UV sunscreens, more readily protected the immune system from photosuppression than from the inflammation of the sunburn reaction, even when applied after exposure, and thus such compounds may have a future role as sun-protective cosmetic ingredients.

Antiosteoporotic Activity

Wende et al. (2004) found that while butanol and methanol red clover extracts had no influence on either alkaline phosphatase or cellular protein production, enzyme activity was increased significantly on incubation with chloroform red clover extracts. The results suggested a role for red clover isoflavonoids in the stimulation of osteoblastic osteosarcoma HOS58 cell differentiation and thus may have potential as a bone-inducing agent. Animal study showed that treatment of ovariectomized Wistar rats with isoflavones significantly increased bone mineral content, mechanical strength of the tibia, femoral weight, femoral density and prevented the rise of serum alkaline phosphatase levels (Occhiuto et al. 2007). In contrast ovariectomy reduced bone mineral content, femoral weight, femoral

density and mechanical strength of the tibia and increased the levels of bone specific alkaline phosphatase in the serum and the number of osteoclasts in the femur sections compared with sham-operated controls. In addition, the treatment with isoflavones significantly reduced the number of osteoclasts compared with the ovariectomized control rats. The findings suggested that red clover isoflavones were effective in reducing bone loss induced by ovariectomy, probably by reducing of the bone turnover via inhibition of bone resorption. Recent studies showed that daily oral administration for 4 weeks of both *Trifolium medium* and *T. pratense* extracts significantly increased the strength of the femoral diaphysis and calcium and phosphorus content in the bone mineral of ovariectomized rats (Cegiela et al. 2012). However, only *T. pratense* extract increased the strength of the tibial metaphysis. The effects of both *Trifolium* extracts differed from those of estradiol which also counteracted the worsening of the tibial strength and increases in bone turnover markers.

Antiangiogenic Activity

In-vivo studies showed that at a dosage of 250 μ g/pellet red clover extract showed excellent inhibition of angiogenesis in the chorioallantoic membrane assay of fertilized hen's eggs (Krenn and Paper 2009). The antiangiogenic activity of the non-methylated isoflavones daidzein and genistein was higher than that of the methylated compounds formononetin and biochanin A. The results demonstrated that red clover extract was not only suitable for menopausal complaints but might also be a powerful chemopreventive agent against chronic diseases especially in elderly females.

Skin-Whitening Activity

The methanol extract from *Trifolium pratense* exerted potent inhibitory activity on melanogenesis in mouse B16 melanoma cells, and the active compound was isolated and identified as

biochanin A (Lin et al. 2011). Biochanin A dose-dependently was found to inhibit both melanogenesis and cellular tyrosinase activity in B16 cells and in zebra fish embryos. Application of a cream containing 2 % biochanin A twice daily to the skin of mice also increased the skin-whitening index value after 1 week of treatment, and the increase continued for another 2 weeks. Biochanin A was confirmed as a good candidate for use as a skin-whitening agent in the treatment of skin hyperpigmentation disorders.

Anti-skin Aging Activity

Studies found that the skin of the ovariectomized rats treated with red clover isoflavones (20 and 40 mg of total isoflavones daily for 14 weeks) appeared well organized with a normal epidermis with uniform thickness and regular keratinization; vascularity, collagen and elastic fibres were well developed (Circosta et al. 2006). In contrast, in untreated ovariectomized rats, the thickness and keratinization of the epidermis were reduced; glands were less in number and vascularity was poor; the distribution and morphology of the collagen bundles and elastic fibres were altered. The amount of collagen significantly increased in the isoflavone treated group in comparison with the control group. The findings suggested that red clover isoflavones were effective in reducing skin aging induced by oestrogen deprivation.

Nociceptive Activity

Studies using tail flicking and formalin tests showed that the pain threshold in ovariectomized rats was reduced due to oestrogen deprivation, whereas the pain threshold levels in ovariectomized rats treated with isoflavones methanol extract from red clover were similar to the control animals (Vishali et al. 2011). The study demonstrated the influence of phytoestrogen on long-term ovariectomized rats in pain perception in the absence of ovarian oestrogen and without toxic side effects.

Pharmacokinetic Studies

Metabolites of the isoflavones were identified in their urine samples of seven women who ingested four red clover dietary supplements (Heinonen et al. 2004). New reduced metabolites of formononetin (dihydroformononetin and angolensin) and biochanin A (dihydrobiochanin A and 6'-hydroxyangolensin) were identified in the urine samples. Studies found intestinal bacteria may influence bioavailability and physiological activity of dietary red clover isoflavones (Braune et al. 2010). In contrast to genistein, irilone was largely resistant to transformation by faecal slurries of ten human subjects. The faecal microbiota converted genistein to dihydrogenistein, 6'-hydroxy-*O*-desmethylangolensin and 2-(4-hydroxyphenyl)-propionic acid. Only one metabolite, namely, dihydroirilone, was formed from irilone in minor amounts. In further experiment, it was found that in contrast to genistein, irilone was not converted by *Eubacterium ramulus*.

In a pilot study of seven volunteers ingesting a single dose of a commercial red clover dietary supplement, the metabolism and bioavailability of the main isoflavones from red clover were monitored (Maul and Kulling 2010). A single intake of an amount of as low as 3.8 mg irilone (out of 38.8 mg total isoflavones) resulted in an irilone plasma concentration of 0.35 μM at 6.5 hours post-ingestion. Compared to the plasma concentrations found for daidzein (0.39 μM) and genistein (0.06 μM), the present findings indicated that irilone might possess a relatively high bioavailability. Additionally, prunetin and pseudobaptigenin were detected in human plasma for the first time.

Proteinase Inhibitory Activity

Maliar et al. (2011) found that *Trifolium pratense* accession POLKIE99-3 expressed the highest relative trypsin inhibition activity (80.0 %) compared to standards. They also found that *Trifolium pratense* genetic resources SVKZAH98-40 possessed relatively high antioxidant properties.

Toxic Red Clover Hay

The mycotoxin slaframine (1-acetoxy-6-amino-octahydroindolizine) was isolated from toxic red clover hay diseased by *Rhizoctonia leguminicola* (Hagler and Behlow 1981). Toxic hay caused extreme salivation, piloerection, lacrimation and respiratory distress and increased defecation when fed to guinea pigs. Similar effects were elicited with purified toxic red clover hay and pure slaframine.

Traditional Medicinal Uses

Red clover is commonly used to treat skin conditions (especially eczema and psoriasis), normally in combination with other purifying herbs, as a folk remedy for breast cancer, menopausal complaint, chronic degenerative diseases, gout, whooping cough and dry coughs (Bown 1995; Chevallier 1996). The flowering heads are alterative, antiscrofulous, antispasmodic, aperient, detergent, diuretic, expectorant, sedative and tonic (Grieve 1971; Duke and Ayensu 1985; Bown 1995).

In Turkish folk medicine, some *Trifolium* species including *T. pratense* and *T. repens* are used for their expectorant, analgesic, antiseptic properties and also to treat rheumatic aches (Sabudak and Guler 2009). *Trifolium pratense* has also gained popularity due to research into its use for the treatment for menopausal symptoms. Traditionally, red clover has been administered to help restore irregular menses and to balance the acid–alkaline level of the vagina to promote conception (Geller et al. 2009). Because the aerial parts of red clover are rich in oestrogenic isoflavones, women have also been using red clover products for the management of vasomotor symptoms related to menopause.

Other Uses

Red clover is one of the richest sources of isoflavones. Red clover is widely grown as a pasture/fodder crop. It is also used as a green manure

crop as it enhances soil fertility by fixing nitrogen. It forms fairly deep tap roots and is useful for remediation of compacted soils especially when grown with grass mixtures. Red clover is also good for weed suppression. The flowers yield a yellow dye.

Comments

Refer also to notes under *Trifolium repens*, white clover, which share numerous similar bioactive phytochemicals and pharmacological properties.

Trifolium repens

Scientific Name

Trifolium repens L.

Synonyms

Lotodes repens Kuntze, *Trifolium limonium* Phil., *Trifolium repens* f. *riparia* Hauman, *Trifolium repens* L. ssp. *giganteum* (Lagr.-Fossat) Ponert, *Trifolium repens* L. var. *giganteum* Lagr.-Fossat, *Trifolium stipitatum* Clos

Family

Fabaceae, also placed in Papilionaceae

Common/English Names

Honeysuckle Clover, Ladino Clover, Lodi Clover, Dutch Clover, Dutch White Clover, White Clover, White Sweet Clover

Vernacular Names

Brazil: Trevo Branco (Portuguese)

Chinese: Bai Che Zhou Cao, Bai Hua San Ye Cao, Bai San Ye Cao, San Xiao Cao

Czech: Jetel Plazivý, Jetel Plazivý Bílý, Jetelovec Plazivý

Danish: Hvid Kløver

Dutch: Schapebloem, Witte Klaver

Eastonian: Valge Ristik

Esperanto: Trifolio Blanka

Finnish: Valkoapila

French: Trèfle Blanc, Trèfle De Hollande, Trèfle Rampant

Gaelic: Seamair Bhán

German: Kriech-Klee, Kriechender Klee, Kriechender Weiss-Klee, Lämmer-Klee, Weiss-Klee, Weisser Wiesen-Klee

Hebrew: Tiltan Zochel

Hungarian: Fehér Here, Kúszó Here

Icelandic: Hvítmári

India: Safed Tipatiya Ghaas (Hindi)

Indonesia: Semanggi Landi (Java)

Italian: Trifoglio Bianco, Trifoglio Ladino, Trifoglio Rampicante

Japanese: Oranda Genge, Shiro Kurooba, Shiro Tsume Kusa

Norwegian: Hvitkløver, Kvitkløver, Okseblom, Smære, Småkløver

Polish: Koniczyna Biała

Portuguese: Trevo-Branco, Trevo-Coroa-De-Rei, Trevo-Da-Holanda, Trevo-Ladino, Trevo-Rasteiro

Russian: Klever Belyj, Klever Polzuchii

Slovaščina: Bela Detelja, Detelja Plazeča, Plazeča Detelja

Slovenčina: Ďatelina Plazivá

Spanish: Trébol Amargo, Trébol Blanco, Trébol Rastrero

Swedish: Hvitklöfver, Krypklöver, Vitklöver, Vitvåpling

Taiwan: Shu Cao

Thai: Thua Clover

Turkish: Aküçgül, Yonca, Yonca Beyaz

Vietnamese: Chê Ba, Cỏ Ba Lá Hà Lan, Cỏ Ba Lá Hoa Trắng

Welsh: Meillion Gwyn

Origin/Distribution

White clover is native to Mediterranean Europe, North Africa and West Asia and has been used as a pasture legume in both Europe and the British Isles for centuries. It is also cultivated as a pasture crop in many cool temperate and subtropical parts of the world such as North America, southern Latin America, South Africa, Australasia, China and Japan. It has naturalized in many of these areas.

Agroecology

White clover grows in turfgrass, crops and landscapes. It is also found in a wide range of different soil type environments but less vigorously on acid, poorly drained or shallow, drought-prone soils especially soils with toxic levels of exchangeable aluminium and manganese. It thrives on moisture-retentive but free-draining soils with adequate soil pH, 5.8–6.0 on mineral soils and 5.5–5.8 on peaty soils. Optimum temperature for growth is 20–25 °C. It tolerates moderate but not severe drought.

Edible Plant Parts and Uses

Young leaves and flower heads are eaten (Cribb and Cribb 1976; Launert 1981; Facciola 1990; Schofield 2003). Clovers are a valuable survival food: they are high in protein, are widespread, are abundant and are eaten boiled or cooked as potherb, in soups and also used in salads. The dried leaves impart a vanilla flavour to cakes and other confectionery. Young flower heads can be used in salads. Dried flower heads and seedpods can also be ground into nutritious flour and mixed with other foods such as rice. Dried flower heads also can be steeped in hot water for a healthy, tasty

tea-like infusion. Roots are also edible cooked (Kunkel 1984; Schofield 2003). The high quercetin concentration and soyasaponin occurrence make the seeds of some *Trifolium* species (*T. repens*, *T. pratense*) a potential source of health beneficial phytochemicals for use in human nutrition (Sabudak and Guler 2009).

Botany

Glabrous perennial, low growing, herbaceous plant, rooting at nodes with trifoliate leaves arranged alternately. Leaflets broadly ovate or circular, rounded or retuse at the tip and usually with whitish leaf markings on the upper mid surface (Plates 1 and 2). Stipules pale and translucent with a short point and broad at the base. Leaf sizes vary from very small in the prostrate, short-

Plate 1 White Clover pasture crop

Plate 2 Close view of leaves and inflorescence

petiolate types to large in the longer-petiolate, more erect cultivar types. Stolons initiated from leaf axils form a branched network radiating from an initially tap-rooted seedling. Inflorescences are globular racemes, 15–25 mm across, with 20–40 florets at the end of long peduncles originating from leaf axils on the stolons (Plates 1 and 2). Flowers scented; calyx 2–6 mm, 10-nerved with unequal teeth; corolla white often tinged pink, becoming deflexed with age with 8–13 mm long vexillum. Fruit linear, 3–4-seeded legume. Seeds cordate with a smooth surface, bright yellow to yellowish brown, becoming darker with age.

Nutritive/Medicinal Properties

Plant/Shoot Phytochemicals

White clover had been reported to be high in protein and minerals (Anonymous 2005; Frame and Newbould 1986; Frame et al. 1998), containing 22–28 % crude protein, 2.7–3.3 % crude fat, 9.4–11.9 % ash, 6.6–7 % lignin and a crude fibre content of 15.7–21.1 % (Anonymous 2005). White clover was reported to contain per kg dry matter: 26.6–5.3 g N, 1.9–4.7 g P, 15.4–38.0 g K, 12.0–23.1 g Ca, 1.4–2.9 g Mg, 2.4–3.6 g S, 0.5–4.6 g Na, 3.4–25.6 g Cl, 102–448 mg Fe, 40–87 mg Mn, 22–32 mg Zn, 5.4–9.7 mg Cu, 0.10–0.38 mg Co, 0.14–0.44 mg I, 1.3–14.2 mg Mo, 0.005–153 mg Se and 26–50 mg B (Frame and Newbould 1986). As animal forage, white clover contributes optimally as a 10–20 % component when grown in conjunction with other grasses (Anonymous 2005). It was found to be more digestible than other temperate forage legumes and therefore the ingested nutrients could be utilized more efficiently.

Healthy and stressed white clover plants contained many types of secondary metabolite such as flavonols, flavones, condensed tannins, isoflavones, isoflavanones, pterocarpanes, coumestans, cyanogenic glucosides and saponins in various plant tissues (Carlsen and Fomsgaard 2008). Many of these bioactive compounds from white clover could be exploited for suppressing weeds

and soil-borne diseases. The oil yield for *T. repens* was small 0.021 % (weight/fresh weight basis) (Tava et al. 2009). Several classes of compounds were found in the oil, including alcohols, aldehydes, ketones, terpenes, esters, hydrocarbons, phenolics and acids.

HE strains of white clover in New Zealand were reported to contain the cyanogenetic glucosides lotaustralin and linamarin, the glucosides of methylethylketone cyanhydrin and acetone cyanohydrin, respectively (Butler and Butler 1960). The isoflavones genistein, biochanin A and formononetin were found in glycosidic forms in white clover and insignificant amount of coumestrol (Francis et al. 1967). The cyanogenic glucosides linamarin and lotaustralin were isolated as a mixture from *Trifolium repens* (Maher and Hughes 1971). α -Hydroxy-methylbutyronitrile- β -D-glucoside was found in white clover (Hughes and Conn 1976). Linamarin and lotaustralin were identified in *T. repens* cv. Armenia in concentrations of 1.29 and 3.13 mg/g of dry matter, respectively (Stochmal and Oleszek 1994). The linamarin/lotaustralin ratio ranged from 0.4 to 0.8 and was inversely correlated with the total cyanogen content; cultivars with higher cyanogen level had a lower linamarin/lotaustralin ratio (Stochmal and Oleszek 1997). At temperatures below 15 °C all varieties contained the highest cyanogen content; an increase in temperature during the summer time resulted in a drastic decrease in cyanogen synthesis.

In leaves, petioles, roots and nodules of white clover, pinitol (3-O-methyl-chiro-inositol) was found to be the predominant sugar, with sucrose present in lower amount (Davis and Nordin 1983). Significant amounts of α -methyl glucoside and β -methyl glucoside, linamarin, glucose and fructose were found in the leaves and petioles. In the nodules, glucose was rarely present at detectable levels. Malonic acid did not appear to be present in unusually high concentrations in either leaves or nodules.

From white clover plant, sapogenins soyasapogenols A, B and C were isolated (Walter et al. 1955). From the whole plant of white clover, five triterpenoid saponins, designated cloversaponins I–V, were isolated together with four known

saponins, β -D-glucuronopyranosylsoyasapogenol B, soyasaponin I, soyasaponin II, azukisaponin II as their methyl esters and astragaloside VIII (Sakamoto et al. 1992).

Phytoestrogens isolated from ladino clover included genistein, biochanin A, formononetin and most significantly coumestrol (Bickoff et al. 1957, 1958, 1960, 1962; Guggolz et al. 1961). Sachse (1974) reported five estrogenic isoflavones—biochanin A, formononetin, pratensein, genistein, daidzein—and the estrogenic coumarin derivate coumestrol in 32 white clover varieties. Other phenolic compounds isolated from ladino clover included 3',4',7-trihydroxyflavone (Livingston and Bickoff 1964), daphnoretin (2-hydroxy-6-methoxy-3-(2-oxochromen-7-yl)oxochromen-7-one) (Livingston et al. 1964a), trifoliol (3,7-dihydroxy-9-methoxy-6H-benzofuro(3,2,-c)-1-benzopyran-6-one) (Livingston et al. 1964b; Bickhoff et al. 1965a) and 7,4'-dihydroxyflavone (Bickhoff et al. 1965b). An acetylated isoflavone, genistein 7-(2''-p-coumaroylglucoside), genistein (Saxena and Jain 1986), 2''-O-acetylated formononetin and formononetin (Saxena and Jain 1989) were identified in *Trifolium repens*. Saloniemi et al. (1993) found the following isoflavones daidzein, formononetin, genistein and biochanin A in white clover varieties.

Flavones 4',5,6,7,8-pentahydroxy-3-methoxyflavone and 5,6,7,8-tetrahydroxy-3-methoxyflavone, as well as two flavones 3,7-dihydroxy-4'-methoxyflavone and 5,6,7,8-tetrahydroxy-4'-methoxyflavone, were isolated from white clover shoots (Ponce et al. 2004). The known quercetin, rhamnetin, acacetin, 7-hydroxy-4'-methoxyflavonol; 3,5,6,7,8-pentahydroxy-4'-methoxyflavone; 2',3',4',5',6'-pentahydroxy-chalcone; 6-hydroxykaempferol; 4',5,6,7,8-pentahydroxyflavone; and 3,4'-dimethoxykaempferol were also obtained.

Two bicoumarins, named repensin A and B, were isolated from *Trifolium repens* and their structures established as 7-methoxy-7',8'-dihydroxy-8,6'-bicoumarinyl and 7,5'-dihydroxy-3,6'-bicoumarinyl, respectively (Zhan et al. 2003). Shoots of *T. repens* were found to contain cyanogenic glycosides, mostly linamarin (α -hydroxyisobutyronitrile- β -D-glucopyranoside)

and a smaller proportion of lotaustralin (2-hydroxy-2-methylbutyronitrile- β -D-glucopyranoside) that breaks down to release toxic hydrogen cyanide when damaged (Gleadow et al. 2009).

In all tissues of clover seedlings not infected by the stem nematode, *Ditylenchus dipsaci*, isoflavonoids occurred predominantly as their glycosidic conjugates, in the order roots > meristems > leaves with formononetin-7-O-glucoside-6''-O-malonate (FGM) and medicarpin-3-O-glucoside-6''-O-malonate (MGM) as the major metabolites (Cook et al. 1995). The conjugates accumulated with age in all tissues and no differences were observed between the isoflavonoid content of healthy susceptible and resistant plants. Infection with either *D. dipsaci* race (oat and clover) elicited the accumulation of medicarpin, MGM and FGM in the meristems to a similar degree in resistant and susceptible seedlings. However, formononetin accumulated only in the infected meristems of the resistant plants. Johnson et al. (2005) found that different flavonoids increased in concentration in plants without rhizobial nodules than in plants with active or inactive nodules. The concentration of 4',7-dihydroxyflavone was higher in plants without rhizobial nodules than in plants with active or inactive nodules. The content of formononetin was higher in roots with active rhizobial nodules than in inactive nodules and roots alone. Flavonol contents of white clover seeds (2.8–2,000 mg/g), leaves (<2–1,700 mg/g) and total above-ground material (20–2,210 mg/g) were higher than in roots (n.d.–208 mg/g) and flowers (66–481 mg/g) (Carlsen et al. 2008).

Leaf Phytochemicals

L-pipecolinic acid (piperidine-2-carboxylic acid) was isolated from the leaves (Morrison 1953) and a leaf protease (Brady 1961). Four coumestans detected in white clover infected with various foliar pathogens and were identified as coumestrol, 12-O-methylcoumestrol, trifoliol and 7,10,12-trihydroxycoumestan (repensol) (Wong and Latch 1971a; 1971b); other phenolic compounds found in diseased white clover included isorhamnetin; 4',7-dihydroxyflavonol;

kaempferol; quercetin; 4',7-dihydroxyflavone; 3',4'',7-trihydroxyflavone; geraldone; luteolin; formononetin; daphnoretin; and a trihydroxycoumestan (Wong and Latch 1971b). White clover contained the phytoalexin medicarpin (Gustine 1981). Isoflavonoids medicarpin and demethylmedicarpin were detected in the droplet of white clover leaflets inoculated with *Monilia fructicola*; several minor isoflavonoids detected in the extracts were identified as formononetin (7-hydroxy-4'-methoxyisoflavone), 2'-hydroxyformononetin and vestitone (7,2'-dihydroxy-4'-methoxyisoflavanone) (Woodward 1981). The following isoflavonoid phytoalexins were detected in fungus-inoculated leaflets: 7,2',4'-trihydroxyisoflavanone, vestitone, medicarpin, demethylmedicarpin, variabilin, sativan, vestitol, genistein, formononetin, glycitein and daidzein (Ingham 1978, 1982).

In white clover, decreased foliar protein coincided with an increased number of protease isoforms (Kingston-Smith et al. 2003). Major flavonoids in the leaves were found to be derivatives of quercetin and kaempferol (Hofmann et al. 2000). Total leaf flavonoids in *Trifolium repens* were found to be low only 1 mg/g compared to 50–65 mg/g for *T. dubium* and *Lotus corniculatus* and up to 15 mg/g for *T. pratense* (de Rijke et al. 2004). In *T. pratense* and *T. repens*, the main constituents were flavonoid glucoside-(di)malonates, while *T. dubium* and *L. corniculatus* mainly contained flavonoid (di)glycosides.

Leaf and Flower Phytochemicals

A total of 12 flavonoids, pterocarpin and methyl caffeate were isolated from leaves and flowers and identified as quercetin 3-*O*-(6''- α -rhamnopyranosyl-2''- β -xylopyranosyl)- β -galactopyranoside (1), kaempferol 3-*O*-(6''- α -rhamnopyranosyl-2''- β -xylopyranosyl)- β -galactopyranoside (2), kaempferol 3-*O*-(2'',6''- α -dirhamnopyranosyl)- β -galactopyranoside, mauritianin(3), quercetin 3-*O*-(2''- β -xylopyranosyl)- β -galactopyranoside (4), kaempferol 3-*O*-(2''- β -xylopyranosyl)- β -galactopyranoside (5), kaempferol 3-*O*- β -(6''-*O*-acetyl)-galactopyranoside (6),

quercetin 3-*O*- β -(6''-*O*-acetyl)-galactopyranoside (7), trifolin (8), hyperoside (9), myricetin 3-*O*- β -galactopyranoside (10), quercetin (11), ononin (12), medicarpin 3-*O*- β -glucopyranoside (13) and methyl caffeate (14) (Kicel and Wolbiś 2012b).

Flower Phytochemicals

More than 50 compounds were identified in the essential oil samples of red and white Austrian clover flowers (Buchbauer et al. 1996). The main constituents (concentration >2 %) were maltol (8.2 %), linalool (4.2 %), 1-phenylethyl alcohol (3.2 %), phenol (2.9 %), phenylethyl acetate (2.7 %), acetophenone (2.4 %) and (*Z*)-3-hexenyl acetate (2.2 %) for red clover flowers and maltol (5.3 %), linalool (3.8 %), phenol (3.6 %), phenylethyl acetate (3.3 %) and 2-phenylethyl alcohol (2.8 %) for white clover flowers.

Major flavonoids in white clover flowers were identified as glycosidic derivatives of quercetin and myricetin (Foo et al. 2000; Schittko et al. 1999). Three main flavonoid components of flower extracts, quercetin-3-*O*-galactoside, its 6''-*O*-acetyl derivative and myricetin-3-*O*-galactoside, were isolated from the flowers (Schittko et al. 1999). White clover flowers were found to contain an abundance of phenolics, namely, quercetin myricetin, *cis-p*-coumaric acid 4-*O*- β -D-glucopyranoside; *trans-p*-coumaric acid 4-*O*- β -D-glucopyranoside; the 3-*O*- β -D-galactopyranosides of myricetin, quercetin and kaempferol together with two new derivatives, namely, myricetin 3-*O*-(6''-acetyl)- β -D-galactopyranoside and kaempferol 3-*O*-(6''-acetyl)- β -D-galactopyranoside (Foo et al. 2000). Gallocatechin, epigallocatechin, gallocatechin-(4 α -8)-epigallocatechin and their corresponding prodelphinidin polymers were also present. The following coumarins umbelliferone, scopoletin, repensin B, daphnoretin and daphnorin (daphnoretin 7-*O*- β -D-glucoside) were isolated from the flowers (Kicel and Wolbiś 2012a). Coumarins, bicoumol (7,7'-dihydroxy-6,8'-bicomariny) and umbelliferone (7-hydroxycoumarin) were found in ladino clover (Spencer et al. 1967). Floral tissues in white clover plants were found to produce both proanthocyanidins and antho-

cyanins (Abeynayake et al. 2012). The white clover floral prodelphinidins were found to consist of terminal units with nearly equal proportions of epigallocatechin (52 %) and gallocatechin (48 %) and extender units showing epigallocatechin (56 %) and gallocatechin (39 %) (Sivakumaran et al. 2004). Tannins were found to accumulate in the flowers of white clover but not in the leaves or stolons (Anonymous 2005).

Seed Phytochemicals

Aqueous extracts of white clover seeds were found to contain myricetin, which was not toxic to *Rhizobium trifolii*, and condensed tannins (prodelphinidins) which were separated into three fractions each of which was toxic to *R. trifolii* (Young and Paterson 1980). The three tannin fractions, one of which had molecular weight of 6,000–12,000 and the other 2,6000–18,000, produced delphinidin on hydrolysis. A natural substance, 2,3-dihydroxy-2,4-cyclopentadien-1-one, was isolated from the seeds along with kaempferol, quercetin and myricetin (Nakatani et al. 1989). The flavonol quercetin and saponins astragaloside VIII, soyasaponin I 22-*O*-glucoside and soyasaponin I 22-*O*-diglucoside were found in the seeds (Oleszek and Stochmal 2002). Main flavonoids found in the seeds were quercetin, myricetin and kaempferol (Prati et al. 2007).

Germinated white clover seeds were found to contain oligosaccharides and galactomannans and enzymes, 5 α -galactosidases I–V (Williams et al. 1978), galactomannans, manno-oligosaccharides and 2 β -mannanases I and II (Villarroya et al. 1978).

Root Phytochemicals

Quercetin, acacetin and rhamnetin accumulated in roots of arbuscular mycorrhizal fungus *Glomus intraradices*-inoculated plants, whereas they were not detected in non-inoculated plants. Two isoflavonoids isolated from clover roots grown under phosphate stress were characterized as formononetin (7-hydroxy,4'-methoxy

isoflavone) and biochanin A (5,7-dihydroxy,4'-methoxy isoflavone) (Nair et al. 1991). At 5 ppm, both compounds stimulated hyphal growth in-vitro and root colonization of an undescribed vesicular-arbuscular mycorrhiza, a *Glomus* sp. The following flavonoids were found in white clover root exudates which acted as signal compounds for nodulation by *Rhizobium* bacteria: 7,4'-dihydroxyflavone, geraldone and 4'-hydroxy-7-methoxyflavone (Redmond et al. 1968). Quercetin, acacetin and rhamnetin accumulated in roots of mycorrhizal inoculated plants, whereas they were not detected in non-inoculated plants (Ponce et al. 2004). Eight flavonoids kaempferol, medicarpin, demethylmedicarpin coumestrol, daidzein, formononetin, genistein and biochanin A were found in the roots (Carlsen et al. 2008). Only plants colonized with the arbuscular mycorrhizal fungus, *Glomus claroideum*, showed detectable concentrations of either coumestrol or kaempferol (cultivar dependant). Only the concentrations of formononetin and daidzein increased in clover roots in response to infection with *Pythium ultimum*. White clover contained the flavonoid aglycones, formononetin, medicarpin and kaempferol and glycosides kaempferol-Rha-Xyl-Gal and quercetin-Xyl-Gal which it released into the soil (Carlsen et al. 2012).

Antioxidant Activity

T. repens flower and leaf extracts showed antioxidant activity towards DPPH radical with EC₅₀ values ranging from 72.3 to 179.3 μ g/ml, respectively (Kicel and Wolbiś 2013). Significant linear correlations were found between antioxidant potentials of flowers and leaves and total phenolic and flavonoid contents determined (R^2 in the range of 0.97–0.99). The flowers were the richest source of phenolics ranging from 28.7 to 38.8 mg GAE/g and flavonoids, calculated for hyperoside, up to 20 mg HP/g, which hydrolyzed mainly to flavonols (the quercetin level greater than 6 mg/g). *T. repens* was found to be poor in isoflavones; similar quantities of Ca 0.2 mg/g were detected in the flowers and leaves.

Phenolic compounds from leaves and flowers, quercetin 3-*O*-(2"- β -xylopyranosyl)- β -galactopyranoside (4), quercetin 3-*O*- β -(6"-*O*-acetyl)-galactopyranoside (7), hyperoside (9), myricetin 3-*O*- β -galactopyranoside (10) and quercetin (11), were found to have potent antioxidant effect against DPPH, but the most effective were compounds 9, 10 and 11 (EC₅₀ values in the range 7.51–9.52 μ M) (Kicel and Wolbiś 2012b).

Estrogenic Activity

Estrogenic compound coumestrol together with other related compounds, coumestans, had been found in white clover (Bickoff et al. 1969; Wong and Latch 1971a); however their normal levels in plants were very low and estrogenically insignificant. Wong et al. (1971) demonstrated estrogenic activity in diseased white clover samples when fed to mice and sheep. Potencies were in parallel to concentration of coumestans. Phytoestrogens can cause infertility in sheep and cattle (Adams 1995). Cows and ewes fed estrogenic forage may suffer impaired ovarian function, often accompanied by reduced conception rates and increased embryonic loss. In cows, clinical signs resembled those associated with cystic ovaries. The infertility was found to be temporary, reverting to normal within 1 month after abstinence from the oestrogenic feed. However, ewes exposed to oestrogen for prolonged periods may suffer a second form of infertility that was permanent, caused by developmental actions of oestrogen during adult life. There have been sporadic reports of estrogenic problems in animals grazed on white clover (*Trifolium repens*). If affected by foliar disease, white clover may produce higher levels of oestrogenic coumestans including coumestrol, 9-*O*-methyl-coumestrol, trifoliol and repensol (Wong and Latch 1971a; Wong et al. 1971). The estrogenic isoflavone contents in white clover varieties were generally low, consisting mainly of formononetin (90–95 %) and genistein (5–10 %), and their contents did not differ between varieties (Nykänen-Kurki et al. 1993). Saloniemi et al. (1993) also reported that white clover varieties contained very small

quantities of estrogenic isoflavones and coumestrol, and they did not explain the increased weight of the immature rat uterus observed in the biological studies. Some coumestrol was found in the autumn. The oestrogenic effect of white clover on rat uterus was found to be positive, the uterine weight of control rats averaged 21 mg, in test groups from 29 to 66 mg. Bickoff et al. (1969) showed coumestrol to be active in mice and sheep, while some poly-hydroxycoumestans were active in mice. Most growth studies indicated that coumestrol had no effect on the rate of growth of either cattle or sheep. However, some evidence existed which suggested that coumestrol may have beneficial effects on carcass quality in lambs.

Traditional Medicinal Uses

The plant is regarded as antirheumatic, antiscrophulatic, depurative, detergent and tonic and a tincture of the leaves is applied as an ointment for gout (Duke and Ayensu 1985). An infusion of the plant has been used in the treatment of coughs, colds, fevers and leucorrhoea, and flower infusion has been used as an eyewash (Moerman 1998). In Turkish folk medicine, for example, some *Trifolium* species including *T. pratense* and *T. repens* are used for their expectorant, analgesic, antiseptic properties and also to treat rheumatic aches (Sabudak and Guler 2009).

Other Uses

White clover is highly important in the dairy, meat and wool industries, significantly improving yields of these products. It is one of the best quality forage legume and the most important one in grazed pastures of moist temperate regions. White clover is suited to both continuous stocking and rotational grazing systems. It provides highly acceptable and nutritious forage to livestock whether as silage, hay or when grazed at a leafy stage. White clover is protein and mineral rich and retains a high digestibility for animals. Physical, chemical and anatomical features contribute to superior intake of white clover compared with grass.

White clover makes a good green manure crop especially with mixture of *Lolium perenne* as well as a good ground cover in sunny locations. It is also an important honey crop for beekeeping.

The isoflavonoids, formononetin and biochanin A, identified from clover roots, stimulated colonization and growth of white clover, while several other flavonoid compounds were inactive when tested at concentrations of 5 mg/l (Siqueira et al. 1991). The stimulatory effects of these isoflavonoids on plant growth were mediated by vesicular-arbuscular mycorrhizal fungi.

Comments

Refer also to notes under *Trifolium pratense*, red clover, which share numerous similar bioactive phytochemicals imparting many pharmacological effects.

Author's Blurb

TK Lim (Tong Kwee Lim) obtained his Bachelor and Masters in Agricultural Science from the University of Malaya and his PHD (Botanical Sciences) from the University of Hawaii. He worked in the University of Agriculture Malaysia for 20 years as a lecturer and Associate Professor; as Principal Horticulturist for 9 years for the Department of Primary Industries and Fisheries, Darwin, Northern Territory; 6 years as Manager of the Asia and Middle East Team in Plant Biosecurity Australia, Department of Agriculture, Fisheries and Forestry, Australia; and 4 years as Research Program Manager with the Australian Centre for International Agriculture Research (ACIAR), Department of Foreign Affairs and Trade, Australia before he retired from public service. He has published over a hundred scientific papers including several books: “Guava in Malaysia: Production, Pest and Diseases”, “Durian Diseases and Disorders”, “Diseases of Mango in Malaysia”, chapters in books, international refereed journals, conference proceedings (as editor) and technical bulletins in the areas of plant pathology, crop protection, horticulture, agronomy and quarantine science. He was also a reviewer of scientific papers for several international scientific journals. As Principal Horticulturist in Darwin, he and his team were instrumental in establishing the horticultural industry in the Northern Territory, Australia, especially on tropical fruits, vegetables, culinary herbs, spices/medicinal herbs and tropical flowers. During his tenure with Plant Biosecurity, he led a team responsible for conducting pest risk analyses and quarantine policy issues dealing with the import and export of plants and plant

products into and out of Australia for the Middle East and Asian region. During his time with ACIAR, he oversaw and managed international research and development programs in plant protection and horticulture covering a wide array of crops that included fruits, plantation crops, vegetables, culinary and medicinal herbs and spices mainly in southeast Asia and the Pacific. In the course of his four decades of working career he has travelled extensively worldwide to many countries in South Asia, East Asia, southeast Asia, Middle East, Europe, the Pacific Islands, USA and England, and also throughout Malaysia and Australia. Since his tertiary education days he always had a strong passion for crops and took an avid interest in edible and medicinal plants. Over the four decades, he has taken several thousands of photographs of common, known and lesser known edible, medicinal and non-medicinal plants, amassed local literature, local indigenous knowledge, books, and has developed and established close rapport with many local researchers, scientists, growers and farmers during the course of his work and travels. All relevant available and up-to-date information collated on more than a thousand species of edible, medicinal and non-medicinal plants will be provided in a comprehensive reference series fully illustrated with coloured images to help in plant identification. This work will cover scientific names, synonyms, common and vernacular names, origin and distribution, agroecology, edible plant parts and uses, plant habit/description, nutritive and medicinal value, other uses and selected current references. Additional information is provided on the medicinal uses

and pharmacological properties of the plants. This work will be of significant interest to scientists, researchers, practitioners (medical practitioners, pharmacologists, ethnobotanists,

horticulturists, food nutritionists, agriculturists, botanists, herbalogists, herbologists, naturalists, conservationists, extension scientists, teachers, lecturers), students and the general public.

Medical Glossary

- AAD** Allergic airway disease. An inflammatory disorder of the airways caused by allergens.
- AAPH** 2,2'-Azobis(2-amidinopropane) dihydrochloride. A water-soluble azo compound used extensively as a free radical generator, often in the study of lipid peroxidation and the characterization of antioxidants.
- Abeta Aggregation** Amyloid beta protein (Abeta) aggregation is associated with Alzheimer's disease (AD); it is a major component of the extracellular plaque found in AD brains.
- Abdominal Distension** Referring to generalized distension of most or all of the abdomen. Also referred to as stomach bloating often caused by a sudden increase in fibre from consumption of vegetables, fruits and beans.
- Ablation Therapy** The destruction of small areas of myocardial tissue, usually by application of electrical or chemical energy, in the treatment of some tachyarrhythmias.
- Abortifacient** A substance that causes or induces abortion.
- Abortivum** A substance inducing abortion.
- Abscess** A swollen infected, inflamed area filled with pus in body tissues.
- ABTS** 2,2 Azinobis-3-ethylthiazoline-6-sulfonic acid. A type of mediator in chemical reaction kinetics of specific enzymes.
- ACAT** Acyl-CoA: cholesterol acyltransferase.
- ACE** See Angiotensin-Converting Enzyme.
- Acetogenins** Natural products from the plants of the family Annonaceae and are very potent inhibitors of the NADH-ubiquinone reductase (Complex I) activity of mammalian mitochondria.
- Acetyl-CoA Carboxylase (ACC)** Enzyme that catalyzes the biotin-dependent carboxylation of acetyl-CoA to produce malonyl-CoA.
- Acetylcholinesterase (AChE)** Is an enzyme that degrades (through its hydrolytic activity) the neurotransmitter acetylcholine, producing choline.
- Acne Vulgaris** Also known as chronic acne, usually occurring in adolescence, with comedones (blackheads), papules (red pimples), nodules (inflamed acne spots) and pustules (small inflamed pus-filled lesions) on the face, neck and upper part of the trunk.
- Acidosis** Increased acidity, an excessively acid condition of the body fluids.
- Acquired Immunodeficiency Syndrome (AIDS)** An epidemic disease caused by an infection by human immunodeficiency virus (HIV-1, HIV-2), retrovirus that causes immune system failure and debilitation and is often accompanied by infections such as tuberculosis.
- Acridone** An organic compound based on the acridine skeleton, with a carbonyl group at the 9 position.
- ACTH** Adrenocorticotrophic hormone (or corticotropin). A polypeptide tropic hormone produced and secreted by the anterior pituitary gland. It plays a role in the synthesis and secretion of gluco- and mineralocorticosteroids and androgenic steroids.
- Activating Transcription Factor (ATF)** A protein (gene) that binds to specific DNA sequences regulating the transfer or transcription of information from DNA to mRNA.
- Activator Protein-1 (AP-1)** A heterodimeric protein transcription factor that regulates gene

expression in response to a variety of stimuli, including cytokines, growth factors, stress and bacterial and viral infections. AP-1 in turn regulates a number of cellular processes including differentiation, proliferation and apoptosis.

Actoprotective Increasing the body's physical performance.

Actoprotectors Preparations that increase the mental performance and enhance body stability against physical loads without increasing oxygen consumption. Actoprotectors are regarded as a subclass of adaptogens that hold a significant capacity to increase physical performance.

Acute Otitis Media (AOM) See Otitis Media.

Acyl-CoA Dehydrogenases A group of enzymes that catalyzes the initial step in each cycle of fatty acid β -oxidation in the mitochondria of cells.

Adaptogen A term used by herbalists to refer to a natural herb product that increases the body's resistance to stresses such as trauma, stress and fatigue.

Adaptogenic Increasing the resistance of the body to stress.

Addison's Disease Is a rare endocrine disorder. It occurs when the adrenal glands cannot produce sufficient hormones (corticosteroids). It is also known as chronic adrenal insufficiency, hypocortisolism or hypocorticism.

Adenocarcinoma A cancer originating in glandular tissue.

Adenoma A benign tumour from a glandular origin.

Adenopathy Abnormal enlargement or swelling of the lymph node.

Adenosine Receptors A class of purinergic, G-protein-coupled receptors with adenosine as endogenous ligand. In humans, there are four adenosine receptors. A_1 and A_{2A} receptors play roles in the heart, regulating myocardial oxygen consumption and coronary blood flow, while the A_{2A} receptor also has broader antiinflammatory effects throughout the body. These two receptors also have important roles in the brain, regulating the release of

other neurotransmitters such as dopamine and glutamate, while the A_{2B} and A_3 receptors are located mainly peripherally and are involved in inflammation and immune responses.

ADH See Alcohol Dehydrogenase.

Adipocyte A fat cell involved in the synthesis and storage of fats.

Adipocytokine Bioactive cytokines produced by adipose tissues.

Adiponectin A protein in humans that modulates several physiological processes, such as metabolism of glucose and fatty acids, and immune responses.

Adipose Tissues Body fat, loose connective tissue composed of adipocytes (fat cells).

Adaptogen Containing smooth pro-stressors which reduce reactivity of host defense systems and decrease damaging effects of various stressors due to increased basal level of mediators involved in the stress response.

Adrenal Glands Star-shaped endocrine glands that sit on top of the kidneys.

Adrenalectomized Having had the adrenal glands surgically removed.

Adrenergic Having to do with adrenaline (epinephrine) and/or noradrenaline (norepinephrine).

Adrenergic Receptors A class of G protein-coupled receptors that are targets of the noradrenaline (norepinephrine) and adrenaline (epinephrine).

Adulterant An impure ingredient added into a preparation.

Advanced Glycation End Products (AGEs) Resultant products of a chain of chemical reactions after an initial glycation reaction. AGEs may play an important adverse role in process of atherosclerosis, diabetes, aging and chronic renal failure.

Aegilops An ulcer or fistula in the inner corner of the eye.

Afferent Something that so conducts or carries towards, such as a blood vessel, fibre or nerve.

Agammaglobulinaemia An inherited disorder in which there are very low levels of protective immune proteins called immunoglobulins. Cf. X-linked agammaglobulinaemia.

- Agalactia** Lack of milk after parturition (birth).
- Age-Related Macular Degeneration (AMD)** A medical condition of elderly adults that results in a loss of vision in the centre of the visual field (the macula) because of damage to the retina.
- Agglutinin** A protein substance, such as an antibody, that is capable of causing agglutination (clumping) of a particular antigen.
- Agglutination** Clumping of particles.
- Agonist** A drug that binds to a receptor of a cell and triggers a response by the cell.
- Ague** A fever (such as from malaria) that is marked by paroxysms of chills, fever and sweating that recurs with regular intervals.
- AhR** Aryl hydrocarbon receptor. A cytosolic protein transcription factor.
- AIDS** See Acquired Immunodeficiency Syndrome.
- Akathisia** A movement disorder in which there is an urge or need to move the legs to stop unpleasant sensations. Also called restless leg syndrome, the disorder is often caused by long-term use of antipsychotic medications.
- AKT** Serine/threonine kinase (also known as protein kinase B or PKB) plays a critical regulatory role in diverse cellular processes, including cancer progression and insulin metabolism.
- Akt Signalling Pathway** Akt are protein kinases involved in mammalian cellular signalling and inhibit apoptotic processes.
- Akt/FoxO Pathway** Cellular processes involving Akt and FoxO transcription factors that play a role in angiogenesis and vasculogenesis.
- Alanine Transaminase (ALT)** Also called serum glutamic pyruvate transaminase (SGPT) or alanine aminotransferase (ALAT), an enzyme present in hepatocytes (liver cells). When a cell is damaged, it leaks this enzyme into the blood.
- ALAT (Alanine Aminotransferase)** See Alanine Transaminase.
- Albumin** Water-soluble proteins found in egg white, blood serum, milk, various animal tissues and plant juices and tissues.
- Albuminuria** Excessive amount of albumin in the urine, a symptom of severe kidney disease.
- Aldose Reductase, Aldehyde Reductase** An enzyme in carbohydrate metabolism that converts glucose to sorbitol.
- Alexipharmic** An antidote, remedy for poison.
- Alexiteric** A preservative against contagious and infectious diseases and the effects of poisons.
- Alcohol Dehydrogenase (ADH)** An enzyme involved in the breakdown of alcohol.
- Algesic** Endogenous substances involved in the production of pain that is associated with inflammation, e.g. serotonin, bradykinin and prostaglandins.
- Alkaline Phosphatase (ALP)** An enzyme in the cells lining the biliary ducts of the liver. ALP levels in plasma will rise with large bile duct obstruction, intrahepatic cholestasis or infiltrative diseases of the liver. ALP is also present in bone and placental tissues.
- Allergenic** Having the properties of an antigen (allergen), immunogenic.
- Allergic** Pertaining to, caused, affected with or the nature of the allergy.
- Allergic Conjunctivitis** Inflammation of the tissue lining the eyelids (conjunctiva) due to allergy.
- Allergy** A hypersensitivity state induced by exposure to a particular antigen (allergen) resulting in harmful immunologic reactions on subsequent exposures. The term is usually used to refer to hypersensitivity to an environmental antigen (atopic allergy or contact dermatitis) or to drug allergy.
- Allogeneic** Cells or tissues which are genetically different because they are derived from separate individuals of the same species. Also refers to a type of immunological reaction that occurs when cells are transplanted into a genetically different recipient.
- Allografts** Or homografts, a graft between individuals of the same species but of different genotypes.
- Alloknesis** Itch produced by innocuous mechanical stimulation.
- Allostasis** The process of achieving stability, or homeostasis, through physiological or behavioural change.

Alopecia Is the loss of hair on the body.

Alopecia Areata Is a particular disorder affecting hair growth (loss of hair) in the scalp and elsewhere.

ALP See Alkaline Phosphatase.

Alpha-Adrenoceptor Receptors postulated to exist on nerve cell membranes of the sympathetic nervous system in order to explain the specificity of certain agents that affect only some sympathetic activities (such as vasoconstriction and relaxation of intestinal muscles and contraction of smooth muscles).

Alpha Amylase (α -Amylase) A major form of amylase found in humans and other mammals that cleaves alpha-bonds of large sugar molecules.

ALT See Alanine Transaminase.

Alterative A medication or treatment which gradually induces a change and restores healthy functions without sensible evacuations.

Alveolar Macrophage A vigorously phagocytic macrophage on the epithelial surface of lung alveoli that ingests carbon and other inhaled particulate matter. Also called coniothage or dust cell.

Alzheimer's Disease A degenerative, organic, mental disease characterized by progressive brain deterioration and dementia, usually occurring after the age of 50.

Amastigote Refers to a cell that does not have any flagella, used mainly to describe a certain phase in the life cycle of trypanosome protozoans.

Amenorrhoea The condition when a woman fails to have menstrual periods.

Amidolytic Cleavage of the amide structure.

Amoebiasis State of being infected by amoeba such as *Entamoeba histolytica*.

Amoebicidal Lethal to amoeba.

AMPK (5' AMP-Activated Protein Kinase) Or 5' adenosine monophosphate-activated protein kinase, enzyme that plays a role in cellular energy homeostasis.

Amygdalitis Inflammation of one or both tonsils, tonsillitis.

Amyloid Beta ($A\beta$ or Abeta) A peptide of 39–43 amino acids that appear to be the main constituent of amyloid plaques in the brains of Alzheimer's disease patients.

Amyloidosis A disorder that results from abnormal deposition of the protein, amyloid, in various tissues of the body.

Amyotrophic Lateral Sclerosis Or ALS, is a disease of the motor neurons in the brain and spinal cord that control voluntary muscle movement.

Amyotrophy Progressive wasting of muscle tissues. *Adj.* amyotrophic.

Anaemia A blood disorder in which the blood is deficient in red blood cells and in haemoglobin.

Anaesthesia Condition of having sensation temporarily suppressed.

Anaesthetic A substance that decreases partially or totally nerve the sense of pain.

Analeptic A central nervous system (CNS) stimulant medication.

Analgesia Term describing relief, reduction or suppression of pain. *Adj.* analgetic.

Analgesic A substance that relieves or reduces pain.

Anaphoretic An antiperspirant.

Anaphrodisiac Or antiaphrodisiac is something that reduces or blunts the libido.

Anaphylaxis A severe, life-threatening allergic response that may be characterized by symptoms such as reduced blood pressure, wheezing, vomiting or diarrhoea.

Anaphylactic *Adj.* see Anaphylaxis.

Anaphylatoxins Are fragments (C3a, C4a or C5a) that are produced during the pathways of the complement system. They can trigger release of substances of endothelial cells, mast cells or phagocytes, which produce a local inflammatory response.

Anaplasia A reversion of differentiation in cells and is characteristic of malignant neoplasms (tumours).

Anaplastic *Adj.* see Anaplasia.

Anasarca Accumulation of great quantity of fluid in body tissues.

Androgen Male sex hormone in vertebrates. Androgens may be used in patients with breast cancer to treat recurrence of the disease.

Android Adiposity Centric fat distribution patterns with increased disposition towards the abdominal area, visceral fat—apple shaped. Cf. gynoid adiposity.

- Andrology** Branch of medicine concerned with the reproductive diseases in men.
- Anencephaly** A cephalic disorder that results from a neural tube defect that occurs when the cephalic (head) end of the neural tube fails to close, resulting in the absence of a major portion of the brain, skull and scalp.
- Aneugen** An agent that affects cell division and the mitotic spindle apparatus, causing the loss or gain of whole chromosomes, thereby inducing aneuploidy. *Adj.* aneugenic.
- Angina Pectoris, Angina** Chest pain or chest discomfort that occurs when the heart muscle does not get enough blood.
- Angioedema** Rapid swelling of the dermis, subcutaneous tissues and mucosa and submucosal tissues caused by small blood vessels leaking fluid into these tissues.
- Angiogenic** *Adj.* see Angiogenesis.
- Angiogenesis** A physiological process involving the growth of new blood vessels from pre-existing vessels.
- Angiotensin** An oligopeptide hormone in the blood that causes blood vessels to constrict and drives blood pressure up. It is part of the renin-angiotensin system.
- Angiotensin-Converting Enzyme (ACE)** An exopeptidase, a circulating enzyme that participates in the body's renin-angiotensin system (RAS) which mediates extracellular volume (i.e. that of the blood plasma, lymph and interstitial fluid) and arterial vasoconstriction.
- Angioplasty** Medical procedure used to open obstructed or narrowed blood vessel resulting usually from atherosclerosis.
- Anguillulosis** A parasitosis caused by the intestinal nematode *Strongyloides stercoralis* (round worm).
- Anisakiasis** A human parasitic infection of the gastrointestinal tract caused by the consumption of raw or undercooked seafood containing larvae of the nematode *Anisakis simplex*.
- Anisonucleosis** A morphological manifestation of nuclear injury characterized by variation in the size of the cell nuclei.
- Ankylosing Spondylitis (AS)** Is a type of inflammatory arthritis that targets the joints of the spine.
- Annexin V** Or Annexin A5 is a member of the annexin family of intracellular proteins that binds to phosphatidylserine (PS) in a calcium-dependent manner.
- Annexitis** Also called adnexitis, a pelvic inflammatory disease involving the inflammation of the ovaries or fallopian tubes.
- Anodyne** A substance that relieves or soothes pain by lessening the sensitivity of the brain or nervous system. Also called an analgesic.
- Anoikis** Apoptosis that is induced by inadequate or inappropriate cell-matrix interactions.
- Anorectal** Relating to the rectum and anus.
- Anorectics** Appetite suppressants, substances which reduce the desire to eat. Used on a short-term basis clinically to treat obesity. Also called anorexigenics.
- Anorexia** Lack or loss of desire to eat.
- Anorexic** Having no appetite to eat.
- Anorexigenics** See Anorectics.
- Anoxia** Absence of oxygen supply.
- Antagonist** A substance that acts against and blocks an action.
- Antalgic** A substance used to relieve a painful condition.
- Antecubital Vein** This vein is located in the antecubital fossa—the area of the arm in front of the elbow.
- Anterior Uveitis** Is the most common form of ocular inflammation that often causes a painful red eye.
- Anthelmintic** An agent or substance that is destructive to worms and used for expulsion of internal parasitic worms in animals and humans.
- Anthocyanins** A subgroup of antioxidant flavonoids, are glucosides of anthocyanidins which are beneficial to health. They occur as water-soluble vacuolar pigments that may appear red, purple or blue according to pH in plants.
- Anthrax** A bacterial disease of cattle and sheep that can be transmitted to man through unprocessed wool.
- Anthropometric** Pertaining to the study of human body measurements.
- Antiamoebic** A substance that destroys or suppresses parasitic amoebae.

- Antiamyloidogenic** Compounds that inhibit the formation of Alzheimer's β -amyloid fibrils (fA β) from amyloid β -peptide (A β) and destabilize fA β .
- Antianaphylactic** Agent that can prevent the occurrence of anaphylaxis (life-threatening allergic response).
- Antiangiogenic** A drug or substance used to stop the growth of tumours and progression of cancers by limiting the pathologic formation of new blood vessels (angiogenesis).
- Antiarrhythmic** A substance to correct irregular heartbeats and restore the normal rhythm.
- Antiasthmatic** Drug that treats or ameliorates asthma.
- Antiatherogenic** That protects against atherogenesis, the formation of atheromas (plaques) in arteries.
- Antibacterial** Substance that kills or inhibits bacteria.
- Antibilious** An agent or substance which helps remove excess bile from the body.
- Antibiotic** A chemical substance produced by a microorganism which has the capacity to inhibit the growth of or to kill other microorganisms.
- Antiblenorrhagic** A substance that treats blenorrhagia a conjunctival inflammation resulting in mucus discharge.
- Antibody** A gamma globulin protein produced by a kind of white blood cell called the plasma cell in the blood used by the immune system to identify and neutralize foreign objects (antigen).
- Anticarcinomic** A substance that kills or inhibits carcinomas (any cancer that arises in epithelium/tissue cells).
- Anticephalalgic** Headache-relieving or preventing.
- Anticestodal** A chemical destructive to tapeworms.
- Anticholesterolemic** A substance that can prevent the buildup of cholesterol.
- Anticlastogenic** Having a suppressing effect of chromosomal aberrations.
- Anticoagulant** A substance that thins the blood and acts to inhibit blood platelets from sticking together.
- Antidepressant** A substance that suppresses depression or sadness.
- Antidiabetic** A substance that prevents or alleviates diabetes. Also called antidiabetogenic.
- Antidiarrhoeal** Having the property of stopping or correcting diarrhoea, an agent having such action.
- Antidote** A remedy for counteracting a poison.
- Antidopaminergic** A term for a chemical that prevents or counteracts the effects of dopamine.
- Antidrepanocytary** Anti-sickle-cell anaemia.
- Antidysenteric** An agent used to reduce or treat dysentery and diarrhoea.
- Antidyslipidaemic** Agent that will reduce the abnormal amount of lipids and lipoproteins in the blood.
- Anti-oedematous Reduces** or suppresses oedema.
- Antiemetic** An agent that stops vomiting and nausea.
- Antiepileptic** A drug used to treat or prevent convulsions, anticonvulsant.
- Antifebrile** A substance that reduces fever. Also called antipyretic.
- Antifeedant** Preventing something from being eaten.
- Antifertility** Agent that inhibits formation of ova and sperm and disrupts the process of fertilization (antizygotic).
- Antifibrosis** Preventing/retarding the development of fibrosis, i.e. excessive growth and activity of fibroblasts.
- Antifilarial** Effective against human filarial worms.
- Antifungal** An agent that kills or inhibits the growth of fungi.
- Antigen** A substance that prompts the production of antibodies and can cause an immune response. *Adj.* antigenic.
- Antigenotoxic** An agent that inhibits DNA adduct formation, stimulates DNA repair mechanisms and possesses antioxidant functions.
- Antiganacratia** Anti-menstruation.
- Antigastralgie** Preventing or alleviating gastric colic.
- Antihematic** Agent that stops vomiting.
- Antihaemorrhagic** An agent which stops or prevents bleeding.
- Antihepatotoxic** Counteracting injuries to the liver.
- Antiherpetic** Having activity against herpes simplex virus (HSV).

- Antihistamine** An agent used to counteract the effects of histamine production in allergic reactions.
- Antihyperalgesia** The ability to block enhanced sensitivity to pain, usually produced by nerve injury or inflammation, to nociceptive stimuli. *Adj.* antihyperalgesic.
- Antihypercholesterolaemia** Term to describe lowering of cholesterol level in the blood or blood serum.
- Antihypercholesterolemic** Agent that lowers cholesterol level in the blood or blood serum.
- Antihyperlipidemic** Promoting a reduction of lipid levels in the blood or an agent that has this action.
- Antihypersensitive** A substance used to treat excessive reactivity to any stimuli.
- Antihypertensive** A drug used in medicine and pharmacology to treat hypertension (high blood pressure).
- Antiinflammatory** A substance used to reduce or prevent inflammation.
- Antileishmanial** Inhibiting the growth and proliferation of *Leishmania*, a genus of flagellate protozoans that are parasitic in the tissues of vertebrates.
- Antileprotic** Therapeutically effective against leprosy.
- Antilithiatic** An agent that reduces or suppresses urinary calculi (stones) and acts to dissolve those already present.
- Antileukaemic** Anticancer drugs that are used to treat leukaemia.
- Antilithogenic** Inhibiting the formation of calculi (stones).
- Antimalarial** An agent used to treat malaria and/or kill the malaria-causing organism, *Plasmodium* spp.
- Antimelanogenesis** Obstructs production of melanin.
- Antimicrobial** A substance that destroys or inhibits growth of disease-causing bacteria, viruses, fungi and other microorganisms.
- Antimitotic** Inhibiting or preventing mitosis.
- Antimutagenic** An agent that inhibits mutations.
- Antimycotic** Antifungal.
- Antineoplastic** Said of a drug intended to inhibit or prevent the maturation and proliferation of neoplasms that may become malignant by targeting the DNA.
- Antineuralgic** A substance that stops intense intermittent pain, usually of the head or face, caused by neuralgia.
- Antinociception** Reduction in pain: a reduction in pain sensitivity produced within neurons when an endorphin or similar opium-containing substance opioid combines with a receptor.
- Antinociceptive** Having an analgesic effect.
- Antioxytotic** Inhibiting premature labour. Cf. tocolytic.
- Antinutrient** Are natural or synthetic compounds that interfere with the absorption of nutrients and are commonly found in food sources and beverages.
- Antioestrogen** A substance that inhibits the biological effects of female sex hormones.
- Antiphidian** Antivenoms of snake.
- Antiosteoporotic** Substance that can prevent osteoporosis.
- Antioviulatory** Substance suppressing ovulation.
- Antioxidant** A chemical compound or substance that inhibits oxidation and protects against free radical activity and lipid oxidation such as vitamin E, vitamin C or beta-carotene (converted to vitamin B), carotenoids and flavonoids which are thought to protect body cells from the damaging effects of oxidation. Many foods including fruit and vegetables contain compounds with antioxidant properties. Antioxidants may also reduce the risks of cancer and age-related macular degeneration (AMD).
- Antipaludic** Antimalarial.
- Antiperiodic** Substance that prevents the recurrence of symptoms of a disease, e.g. malaria.
- Antiperspirant** A substance that inhibits sweating. Also called antisudorific, anaphoretic.
- Antiphlogistic** A traditional term for a substance used against inflammation, an antiinflammatory.
- Antiplatelet Agent** Drug that decreases platelet aggregation and inhibits thrombus formation.
- Antiplasmodial** Suppressing or destroying plasmodia.
- Antiproliferative** Preventing or inhibiting the reproduction of similar cells.

- Antiprostatic** Drug to treat the prostate.
- Antiprotozoal** Suppressing the growth or reproduction of protozoa.
- Antipruritic** Alleviating or preventing itching.
- Antipyretic** A substance that reduces fever or quells it. Also known as antithermic.
- Antirheumatic** Relieving or preventing rheumatism.
- Antiscorbutic** A substance or plant rich in vitamin C that is used to counteract scurvy.
- Antisecretory** Inhibiting or diminishing secretion.
- Antisense** Refers to antisense RNA strand because its sequence of nucleotides is the complement of message sense. When mRNA forms a duplex with a complementary antisense RNA sequence, translation of the mRNA into the protein is blocked. This may slow or halt the growth of cancer cells.
- Antiseptic** Preventing decay or putrefaction, a substance inhibiting the growth and development of microorganisms.
- Anti-sickling Agent** An agent used to prevent or reverse the pathological events leading to sickling of erythrocytes in sickle-cell conditions.
- Antispasmodic** A substance that relieves spasms or inhibits the contraction of smooth muscles; smooth muscle relaxant, muscle relaxer.
- Antispermatogetic** Preventing or suppressing the production of semen or spermatozoa.
- Antisudorific** See Antiperspirant.
- Antisyphilitic** A drug (or other chemical agent) that is effective against syphilis.
- Antithermic** A substance that reduces fever and temperature. Also known as antipyretic.
- Antithrombotic** Preventing or interfering with the formation of thrombi.
- Antitoxin** An antibody with the ability to neutralize a specific toxin.
- Antitumoural** Substance that acts against the growth, development or spread of a tumour.
- Antitussive** A substance that depresses coughing.
- Antiulcerogenic** An agent used to protect against the formation of ulcers or is used for the treatment of ulcers.
- Antivenin** An agent used against the venom of a snake, spider or other venomous animal or insect.
- Antivinous** An agent or substance that treats addiction to alcohol.
- Antiviral** Substance that destroys or inhibits the growth and viability of infectious viruses.
- Antivomitive** A substance that reduces or suppresses vomiting.
- Antizygotic** See Antifertility.
- Anuria** Absence of urine production and excretion. *Adj.* anuric.
- Anxiogenic** Substance that causes anxiety.
- Anxiolytic** A drug prescribed for the treatment of symptoms of anxiety.
- APAF-1** Apoptotic protease-activating factor 1.
- Apelin** Also known as APLN, a peptide which in humans is encoded by the APLN gene.
- Aperient** A substance that acts as a mild laxative by increasing fluids in the bowel.
- Aperitif** An appetite stimulant.
- Aphonia** Loss of the voice resulting from disease, injury to the vocal cords or various psychological causes, such as hysteria.
- Aphrodisiac** An agent that increases sexual activity and libido and/or improves sexual performance.
- Aphthae** White, painful oral ulcer of unknown cause.
- Aphthous ulcer** Also known as a canker sore, is a type of oral ulcer, which presents as a painful open sore inside the mouth or upper throat.
- Aphthous stomatitis** A canker sore, a type of painful oral ulcer or sore inside the mouth or upper throat, caused by a break in the mucous membrane. Also called aphthous ulcer.
- Apnea** Suspension of external breathing.
- Apolipoprotein B (APOB)** Primary apolipoprotein of low-density lipoproteins which is responsible for carrying cholesterol to tissues.
- Apoplexy** A condition in which the brain's function stops with loss of voluntary motion and sense.
- Apoprotein** The protein moiety of a molecule or complex, as of a lipoprotein.
- Appendicitis** Is a condition characterized by inflammation of the appendix. Also called epityphlitis.
- Appetite Stimulant** A substance to increase or stimulate the appetite. Also called aperitif.

- APPT (Activated Partial Thromboplastin Time)** A blood test, a measure of the part of the blood clotting pathway.
- Apolipoprotein A-I (APOA1)** A major protein component of high-density lipoprotein (HDL) in plasma. The protein promotes cholesterol efflux from tissues to the liver for excretion.
- Apolipoprotein B (APOB)** Is the primary apolipoprotein of low-density lipoproteins (LDL or 'bad cholesterol'), which is responsible for carrying cholesterol to tissues.
- Apolipoprotein E (APOE)** The apolipoprotein found on intermediate density lipoprotein and chylomicron that binds to a specific receptor on liver and peripheral cells.
- Apoplexy** Bleeding within internal organs.
- Apoptogenic** Ability to cause death of cells.
- Apoptosis** Death of cells.
- Apurinic Lyase** A DNA enzyme that catalyzes a chemical reaction.
- Arachidonate Cascade** Includes the cyclooxygenase (COX) pathway to form prostanoids and the lipoxygenase (LOX) pathway to generate several oxygenated fatty acids, collectively called eicosanoids.
- ARE** Antioxidant response element is a transcriptional control element that mediates expression of a set of antioxidant proteins.
- Ariboflavinosis** A condition caused by the dietary deficiency of riboflavin that is characterized by mouth lesions, seborrhoea and vascularization.
- Aromatase** An enzyme involved in the production of oestrogen that acts by catalyzing the conversion of testosterone (an androgen) to estradiol (an oestrogen). Aromatase is located in oestrogen-producing cells in the adrenal glands, ovaries, placenta, testicles, adipose (fat) tissue and brain.
- Aromatic** Having a pleasant, fragrant odour.
- Aromatherapy** A form of alternative medicine that uses volatile liquid plant materials, such as essential oils and other scented compounds from plants for the purpose of affecting a person's mood or health.
- ARPE-19 Cells** A human retinal pigment epithelial cell line with differentiated properties.
- Arrhythmias** Abnormal heart rhythms that can cause the heart to pump less effectively. Also called dysrhythmias.
- Arsenicosis** See Arsenism.
- Arsenism** An incommunicable disease resulting from the ingestion of groundwater containing unsafe levels of arsenic, also known as arsenicosis.
- Arteriogenic Erectile Dysfunction** A penis dysfunction caused by the narrowing of the arteries in the penis, decreasing blood inflow to it, thus making erection impossible.
- Arteriosclerosis** Imprecise term for various disorders of arteries, particularly hardening due to fibrosis or calcium deposition, often used as a synonym for atherosclerosis.
- Arthralgia** Is pain in the joints from many possible causes.
- Arthritis** Inflammation of the joints of the body.
- Aryl Hydrocarbon Receptor (AhR)** A ligand-activated transcription factor best known for mediating the toxicity of dioxin and other exogenous contaminants and is responsible for their toxic effects, including immunosuppression.
- ASAT or AST** Aspartate aminotransferase; see Aspartate Transaminase.
- ASBT** Apical sodium-dependent bile acid transporter, belongs to the solute carrier family (SLC), of transporters and is an important carrier protein expressed in the small intestine.
- Ascaris** A genus of parasitic intestinal round worms.
- Ascites** Abnormal accumulation of fluid within the abdominal or peritoneal cavity.
- Ascorbic Acid** See Vitamin C.
- Aspartate Transaminase (AST)** Also called serum glutamic oxaloacetic transaminase (SGOT) or aspartate aminotransferase (ASAT) and is similar to ALT in that it is another enzyme associated with liver parenchymal cells. It is increased in acute liver damage, but is also present in red blood cells, and cardiac and skeletal muscle and is therefore not specific to the liver.
- Asphyxia** Failure or suppression of the respiratory process due to obstruction of air flow to the lungs or to the lack of oxygen in inspired air.

- Asphyxiation** The process of undergoing asphyxia.
- Asthenia** A nonspecific symptom characterized by loss of energy and strength and feeling of weakness.
- Asthenopia** Weakness or fatigue of the eyes, usually accompanied by headache and dimming of vision. *Adj.* Asthenopic.
- Asthma** A chronic illness involving the respiratory system in which the airway occasionally constricts, becomes inflamed and is lined with excessive amounts of mucus, often in response to one or more triggers.
- Astringent** A substance that contracts blood vessels and certain body tissues (such as mucous membranes) with the effect of reducing secretion and excretion of fluids and/or has a drying effect.
- Astrocytes** Collectively called astroglia, are characteristic star-shaped glial cells in the brain and spinal cord.
- Ataxia** (Loss of coordination) results from the degeneration of nerve tissue in the spinal cord and of nerves that control muscle movement in the arms and legs.
- Ataxia Telangiectasia and Rad3-Related Protein (ATR)** Also known as serine/threonine-protein kinase ATR and FRAP-related protein 1 (FRP1), and is an enzyme encoded by the ATR gene. It is involved in sensing DNA damage and activating the DNA damage checkpoint, leading to cell cycle arrest.
- Atelectasis** The collapse or closure of the lung resulting in reduced or absent gas exchange.
- ATF-2** Activating transcription factor 2.
- Athlete's Foot** A contagious skin disease caused by parasitic fungi affecting the foot and hands, causing itching, blisters and cracking. Also called dermatophytosis.
- Atherogenic** Having the capacity to start or accelerate the process of atherogenesis.
- Atherogenesis** The formation of lipid deposits in the arteries.
- Atheroma** A deposit or degenerative accumulation of lipid-containing plaques on the innermost layer of the wall of an artery.
- Atherosclerosis** The condition in which an artery wall thickens as the result of a buildup of fatty materials such as cholesterol.
- Atherothrombosis** Medical condition characterized by an unpredictable, sudden disruption (rupture or erosion/fissure) of an atherosclerotic plaque, which leads to platelet activation and thrombus formation.
- Athymic Mice** Laboratory mice lacking a thymus gland.
- Atonic** Lacking normal tone or strength.
- Atony** Insufficient muscular tone.
- Atopic Dermatitis** An inflammatory, noncontagious, pruritic skin disorder of unknown aetiology; often called eczema.
- Atresia** A congenital medical condition in which a body orifice or passage in the body is abnormally closed or absent.
- Atretic Follicle** Follicular atresia is the breakdown of the ovarian follicles.
- Atretic Ovarian Follicles** An involuted or closed ovarian follicle.
- Atrial Fibrillation** Is the most common cardiac arrhythmia (abnormal heart rhythm) and involves the two upper chambers (atria) of the heart.
- Attention-Deficit Hyperactivity Disorder (ADHD, ADD or AD/HD)** Is a neurobehavioural developmental disorder, primarily characterized by the coexistence of attentional problems and hyperactivity.
- Auditory Brainstem Response (ABR)** Also called brainstem evoked response (BSER) is an electrical signal evoked from the brainstem of a human by the presentation of a sound such as a click.
- Augmerosen** A drug that may kill cancer cells by blocking the production of a protein that makes cancer cells live longer. Also called bcl-2 antisense oligonucleotide.
- Auricular** Of or relating to the auricle or the ear in general.
- Aurones** [2-Benzylidenebenzofuran-3(2H)-ones] are the secondary plant metabolites and is a subgroup of flavonoids. See Flavonoids.
- Autoantibodies** Antibodies manufactured by the immune system that mistakenly target and

damage specific tissues and organs of the body.

Autolysin An enzyme that hydrolyzes and destroys the components of a biological cell or a tissue in which it is produced.

Autonomic Disorder A neurological disease in which the autonomic nervous system ceases to function properly.

Autophagy Digestion of the cell contents by enzymes in the same cell.

Autopsy Examination of a cadaver to determine or confirm the cause of death.

Avenanthramides Low molecular weight, soluble phenolic compounds found in oats.

Avidity Index Describes the collective interactions between antibodies and a multivalent antigen.

Avulsed Teeth Is tooth that has been knocked out.

Ayurvedic Traditional Hindu system of medicine based largely on homeopathy and naturopathy.

Azoospermia Is the medical condition of a male not having any measurable level of sperm in his semen.

Azotaemia A higher than normal blood level of urea or other nitrogen containing compounds in the blood.

B Cell-Activating Factor (BAFF) Also called tumour necrosis factor ligand superfamily member 13B. It plays an important role in the proliferation and differentiation of B cells.

Babesia A protozoan parasite (malaria-like) of the blood that causes a haemolytic disease known as Babesiosis.

Babesiosis Malaria-like parasitic disease caused by Babesia, a genus of protozoal piroplasms.

Back Tonus Normal state of balanced tension in the tissues of the back.

Bactericidal Lethal to bacteria.

Balanitis Is an inflammation of the glans (head) of the penis.

BALB/c Mice Balb/c mouse was developed in 1923 by McDowell. It is a popular strain and is used in many different research disciplines, but most often in the production of monoclonal antibodies.

Balm Aromatic oily resin from certain trees and shrubs used in medicine.

Baroreceptor A type of interoceptor that is stimulated by pressure changes, as those in blood vessel wall.

Barrett's Oesophagus (Barrett's Oesophagitis) A disorder in which the lining of the oesophagus is damaged by stomach acid.

Basophil A type of white blood cell with coarse granules within the cytoplasm and a bilobate (two-lobed) nucleus.

Bax/Bad Proapoptotic proteins.

BCL-2 A family of apoptosis regulator proteins in humans encoded by the B cell lymphoma 2 (BCL-2) gene.

BCL-2 Antisense Oligonucleotide See Augmereson.

BCR/ABL A chimeric oncogene, from fusion of BCR and ABL cancer genes associated with chronic myelogenous leukaemia.

Bechic A remedy or treatment of cough.

Bed Nucleus of the Stria Terminalis (BNST) Acts as a relay site within the hypothalamic-pituitary-adrenal axis and regulate its activity in response to acute stress.

Belching or Burping Refers to the noisy release of air or gas from the stomach through the mouth.

Beri-BeriIs a disease caused by a deficiency of thiamine (vitamin B1) that affects many systems of the body, including the muscles, heart, nerves and digestive system.

Beta-Carotene Naturally occurring retinol (vitamin A) precursor obtained from certain fruits and vegetables with potential antineoplastic and chemopreventive activities. As an antioxidant, beta-carotene inhibits free radical damage to DNA. This agent also induces cell differentiation and apoptosis of some tumour cell types, particularly in early stages of tumorigenesis, and enhances immune system activity by stimulating the release of natural killer cells, lymphocytes and monocytes.

Beta-CateninIs a multifunctional oncogenic protein that contributes fundamentally to cell development and biology; it has been implicated as an integral component in the Wnt signalling pathway.

Beta Cells A type of cell in the pancreas in areas called the islets of Langerhans.

Beta-Glucans Polysaccharides of D-glucose monomers linked by β -glycosidic bonds, (1 \rightarrow 3), (1 \rightarrow 4)- β -D-glucan, soluble, viscous component of fibres found in cereals like oats.

Beta-Lactamase Enzymes produced by some bacteria that are responsible for their resistance to beta-lactam antibiotics like penicillins.

Beta-Thalassaemia An inherited blood disorder that reduces the production of haemoglobin.

BHT Butylated hydroxytoluene (phenolic compound), an antioxidant used in foods, cosmetics, pharmaceuticals and petroleum products.

Bifidobacterium Is a genus of Gram-positive, nonmotile, often branched anaerobic bacteria. Bifidobacteria are one of the major genera of bacteria that make up the gut flora. Bifidobacteria aid in digestion, are associated with a lower incidence of allergies, and also prevent some forms of tumour growth. Some bifidobacteria are being used as probiotics.

Bifidogenic Promoting the growth of (beneficial) bifidobacteria in the intestinal tract.

Bile Fluid secreted by the liver and discharged into the duodenum where it is integral in the digestion and absorption of fats.

Bilharzia, Bilharziasis See Schistosomiasis.

Biliary Relating to the bile or the organs in which the bile is contained or transported.

Biliary Infections Infection of organ(s) associated with bile and comprises (a) acute cholecystitis, an acute inflammation of the gallbladder wall, and (b) cholangitis, inflammation of the bile ducts.

Biliousness Old term used in the eighteenth and nineteenth centuries pertaining to bad digestion, stomach pains, constipation and excessive flatulence.

Bilirubin A breakdown product of heme (a part of haemoglobin in red blood cells) produced by the liver that is excreted in bile which causes a yellow discoloration of the skin and eyes when it accumulates in those organs.

Biotin Also known as vitamin B7. See Vitamin B7.

Bitter A medicinal agent with a bitter taste and used as a tonic, alterative or appetizer.

Blackhead See Comedone.

Blackwater Fever Dangerous complication of malarial whereby the red blood cells burst in the bloodstream (haemolysis) releasing haemoglobin directly into the blood.

Blain See Chilblain.

Blastocyst Blastocyst is an embryonic structure formed in the early embryogenesis of mammals, after the formation of the morula, but before implantation.

Blastocytotoxic Agent that suppresses further development of the blastocyst through to the ovum stage.

Blebbing Bulging, e.g. membrane blebbing also called membrane bulging or ballooning.

Bleeding Diathesis Is an unusual susceptibility to bleeding (haemorrhage) due to a defect in the system of coagulation.

Blennorrhagia Gonorrhoea.

Blennorrhoea Inordinate discharge of mucus, especially a gonorrhoeal discharge from the urethra or vagina.

Blepharitis Inflammation of the eyelids.

Blister Thin vesicle on the skin containing serum and caused by rubbing, friction or burn.

Blood–Brain Barrier (BBB) Is a separation of circulating blood and cerebrospinal fluid (CSF) in the central nervous system (CNS). It allows essential metabolites, such as oxygen and glucose, to pass from the blood to the brain and central nervous system (CNS) but blocks most molecules that are more massive than about 500 Da.

Boil Localized pyrogenic, painful infection, originating in a hair follicle.

Borborygmus Rumbling noise caused by the muscular contractions of peristalsis, the process that moves the contents of the stomach and intestines downward.

Bowman–Birk Inhibitors Type of serine proteinase inhibitor.

Bouillon A broth in French cuisine.

Bradycardia As applied to adult medicine, is defined as a resting heart rate of under 60 beats per minute.

Bradyphrenia Referring to the slowness of thought common to many disorders of the brain.

- Brain-Derived Neurotrophic Factor (BDNF)** A protein member of the neurotrophin family that plays an important role in the growth, maintenance, function and survival of neurons. The protein molecule is involved in the modulation of cognitive and emotional functions and in the treatment of a variety of mental disorders.
- Bright's Disease** Chronic nephritis.
- Bronchial Inflammation** See Bronchitis.
- Bronchiectasis** A condition in which the airways within the lungs (bronchial tubes) become damaged and widened.
- Bronchitis** Is an inflammation of the main air passages (bronchi) to the lungs.
- Bronchoalveolar Lavage (BAL)** A medical procedure in which a bronchoscope is passed through the mouth or nose into the lungs and fluid is squirted into a small part of the lung and then recollected for examination.
- Bronchopneumonia** Or bronchial pneumonia; inflammation of the lungs beginning in the terminal bronchioles.
- Bronchopulmonary** Relating to the bronchi and lungs.
- Bronchospasm** Is a difficulty in breathing caused by a sudden constriction of the muscles in the walls of the bronchioles as occurs in asthma.
- Brown Fat** Brown adipose tissue (BAT) in mammals; its primary function is to generate body heat in animals or newborns that do not shiver.
- Bubo** Inflamed, swollen lymph node in the neck or groin.
- Buccal** Of or relating to the cheeks or the mouth cavity.
- Bullae** Blisters; circumscribed, fluid-containing, elevated lesions of the skin, usually more than 5 mm in diameter.
- Bursa** A fluid-filled sac or saclike cavity situated in areas subjected to friction.
- Bursitis** Condition characterized by inflammation of one or more bursae (small sacs) of synovial fluid in the body.
- C Fibres** Afferent fibres found in the nerve of the somatic sensory system.
- c-FOS** A cellular proto-oncogene belonging to the immediate early gene family of transcription factors.
- c-Jun I (Ser 73)** Substrate of JNK-1 activated by phosphorylation at Ser73.
- c-Jun II (Ser 63)** Substrate of JNK-1 activated by phosphorylation at Ser63.
- c-Jun NH(2)-Terminal Kinase** Enzymes that belong to the family of the MAPK superfamily of protein kinases. These kinases mediate a plethora of cellular responses to such stressful stimuli, including apoptosis and production of inflammatory and immunoregulatory cytokines in diverse cell systems. *Cf.* MAPK.
- C-Reactive Protein** A protein found in the blood, the levels of which rise in response to inflammation.
- c-Src** A cellular non-receptor tyrosine kinase.
- CAAT Element-Binding Proteins-Alpha (c/EBP-akpha)** Regulates gene expression in adipocytes in the liver.
- Cachexia** Physical wasting with loss of weight, muscle atrophy, fatigue and weakness caused by disease.
- Caco-2 Cell Line** A continuous line of heterogeneous human epithelial colorectal adenocarcinoma cells.
- Cadaver** A dead body, corpse.
- Ca²⁺ ATPase (PMCA)** Is a transport protein in the plasma membrane of cells that serves to remove calcium (Ca²⁺) from the cell.
- Calcitonin Gene-Related Peptide (CGRP)** Is a 37-amino acid neuropeptide that is abundant in the sensory neurons which innervate bone.
- Calcium (Ca)** Is the most abundant mineral in the body found mainly in bones and teeth. It is required for muscle contraction, blood vessel expansion and contraction, secretion of hormones and enzymes and transmission of impulses throughout the nervous system. Dietary sources include milk, yogurt, cheese, Chinese cabbage, kale, broccoli, some green leafy vegetables, fortified cereals, beverages and soybean products.
- Calcium ATPase** Is a form of P-ATPase which transfers calcium after a muscle has contracted.
- Calcium Channel Blockers (CCBs)** A class of drugs and natural substances that disrupt the calcium (Ca²⁺) conduction of calcium channels.

- Calciuria** Abnormal presence of calcium in the urine.
- Calculus** The tendency or deposition to form calculi or stones.
- Calculus (Calculi)** Hardened, mineral deposits that can form a blockage in the urinary system.
- Calculi Infection** Most calculi arise in the kidney when urine becomes supersaturated with a salt that is capable of forming solid crystals. Symptoms arise as these calculi become impacted within the ureter as they pass towards the urinary bladder.
- Caligo** Dimness or obscurity of sight, dependent upon a speck on the cornea.
- Calmodulin** Is a calcium-modulated protein that can bind to and regulate a multitude of different protein targets, thereby affecting many different cellular functions.
- cAMP-Dependent Pathway** Cyclic adenosine monophosphate is a G protein-coupled receptor triggered signalling cascade used in cell communication in living organisms.
- CAMP Factor** Diffusible, heat-stable, extracellular protein produced by Group B *Streptococcus* that enhances the haemolysis of sheep erythrocytes by *Staphylococcus aureus*. It is named after Christie, Atkins and Munch-Peterson, who described it in 1944.
- Campylobacteriosis** Is a gastrointestinal disease (gastroenteritis) caused by bacteria called *Campylobacter* which is frequently associated with the consumption of contaminated poultry.
- Cancer** A malignant neoplasm or tumour in any part of the body.
- Candidiasis** Infections caused by members of the fungus genus *Candida* that range from superficial, such as oral thrush and vaginitis, to systemic and potentially life-threatening diseases.
- Canker** See Chancre.
- Cannabinoid Receptor Family** Includes CB1 cannabinoid receptors found predominantly in the brain and nervous system and CB2 cannabinoid receptors mainly associated with immune tissues and expressed at low levels in the brain.
- Cannabinoid Receptor Type 2 (CB 2 Receptor)** A G protein-coupled receptor from the cannabinoid receptor family that are mainly expressed on T cells of the immune system, on macrophages and B cells and in haematopoietic cells.
- Carboxypeptidase** An enzyme that hydrolyzes the carboxy-terminal (C-terminal) end of a peptide bond. It is synthesized in the pancreas and secreted into the small intestine.
- Carbuncle** Is an abscess larger than a boil, usually with one or more openings draining pus onto the skin.
- Carcinogenesis** Production of carcinomas. *Adj.* carcinogenic.
- Carcinoma** Any malignant cancer that arises from epithelial cells.
- Carcinosarcoma** A rare tumour containing carcinomatous and sarcomatous components.
- Cardiac** Relating to, situated near or affecting the heart.
- Cardiac Asthma** Acute attack of dyspnoea with wheezing resulting from a cardiac disorder.
- Cardiac Hypertrophy** Is a thickening of the heart muscle (myocardium) resulting in a decrease chamber size, including the left and right ventricles. Common causes of cardiac hypertrophy include high blood pressure (hypertension) and heart valve stenosis.
- Cardialgia** Heartburn.
- Cardinolides** Cardiac glycosides with a 5-membered lactone ring in the side chain of the steroid aglycone.
- Cardinolate Glycoside** Cardenolides that contain structural groups derived from sugars.
- Cardioactive** Having an effect on the heart.
- Cardiogenic Shock** Is characterized by a decreased pumping ability of the heart that causes a shock like state associated with an inadequate circulation of blood due to primary failure of the ventricles of the heart to function effectively.
- Cardiomyocytes** Cardiac muscle cells.
- Cardiomyopathy** Heart muscle disease.
- Cardiopathy** Disease or disorder of the heart.
- Cardioplegia** Stopping the heart so that surgical procedures can proceed in a still and bloodless field.
- Cardiotonic** Something which strengthens, tones or regulates heart functions without overt stimulation or depression.

- Cardiovascular** Pertaining to the heart and blood vessels.
- Caries** Tooth decay, commonly called cavities.
- Cariogenic** Leading to the production of caries.
- Carminative** Substance that stops the formation of intestinal gas and helps expel gas that has already formed, relieving flatulence: relieving flatulence or colic by expelling gas.
- Carnitine Palmitoyltransferase I (CPT1)** Also known as carnitine acyltransferase I or CAT1 is a mitochondrial enzyme, involved in converting long chain fatty acid into energy.
- Carotenes** Are a large group of intense red and yellow pigments found in all plants; these are hydrocarbon carotenoids (subclass of tetraterpenes) and the principal carotene is beta-carotene which is a precursor of vitamin A.
- Carotenoids** A class of natural fat-soluble pigments found principally in plants, belonging to a subgroup of terpenoids containing eight isoprene units forming a C40 polyene chain. Carotenoids play an important potential role in human health by acting as biological antioxidants. See also Carotenes.
- Carotenodermia** Yellow skin discoloration caused by excess blood carotene.
- Carpopedal Spasm** Spasm of the hand or foot or of the thumbs and great toes.
- Capases** Cysteine-aspartic acid proteases, are a family of cysteine proteases, which play essential roles in apoptosis (programmed cell death), necrosis and inflammation.
- Catalase (CAT)** Enzyme in living organism that catalyzes the decomposition of hydrogen peroxide to water and oxygen.
- Catalepsy** Indefinitely prolonged maintenance of a fixed body posture; seen in severe cases of catatonic schizophrenia.
- Catamenia** Menstruation.
- Cataplasia** Degenerative reversion of cells or tissue to a less differentiated form.
- Cataplasma** A medicated poultice or plaster. A soft moist mass, often warm and medicated, that is spread over the skin to treat an inflamed, aching or painful area, to improve the circulation.
- Cataractogenesis** Formation of cataracts.
- Catarrh, Catarrhal** Inflammation of the mucous membranes especially of the nose and throat.
- Catechins** Are polyphenolic antioxidant plant metabolites. They belong to the family of flavonoids; tea is a rich source of catechins. See Flavonoids.
- Catecholamines** Hormones that are released by the adrenal glands in response to stress.
- Cathartic** Is a substance which accelerates defecation.
- Caustic** Having a corrosive or burning effect.
- Cauterization** A medical term describing the burning of the body to remove or close a part of it.
- Caveolae** Tiny (50–100 nm) invaginations of the plasma membrane of the cell.
- CB-1 Receptor** Cannabinoid receptor type 1 held to be one of the most widely expressed G protein-coupled receptors in the brain.
- cdc2 Kinase** A member of the cyclin-dependent protein kinases (CDKs).
- CDKs** Cyclin-dependent protein kinases, a family of serine/threonine kinases that mediate many stages in mitosis.
- CD4T cell** Helper T cell with CD4 receptor that recognizes antigens on the surface of a virus-infected cell and secretes lymphokines that stimulate B cells and killer T cells.
- CD28** Is one of the molecules expressed on T cells that provide co-stimulatory signals, which are required for T cell (lymphocytes) activation.
- CD31** Also known as PECAM-1 (platelet endothelial cell adhesion molecule-1), a member of the immunoglobulin superfamily, that mediates cell-to-cell adhesion.
- CD36** An integral membrane protein found on the surface of many cell types in vertebrate animals.
- CD40** An integral membrane protein found on the surface of B lymphocytes, dendritic cells, follicular dendritic cells, haematopoietic progenitor cells, epithelial cells and carcinomas.
- CD68** A glycoprotein expressed on monocytes/macrophages which binds to low-density lipoprotein.
- Cecal Ligation** tying up the caecum.
- Celiac Disease** An autoimmune disorder of the small intestine, triggered in genetically susceptible individuals by ingested gluten from

wheat, rye, barley and other closely related cereal grains. Peptides resulting from partially digested gluten of wheat, barley or rye cause inflammation of the small intestinal mucosa.

CellAdhesionMolecules(CAM) Glycoproteins located on the surface of cell membranes involved with binding of other cells or with the extracellular matrix.

Cellular Respiration Is the set of the metabolic reactions and processes that take place in organisms' cells to convert biochemical energy from nutrients into adenosine triphosphate (ATP) and then release waste products. The reactions involved in respiration are catabolic reactions that involve the oxidation of one molecule and the reduction of another.

Cellulitis A bacterial infection of the skin that tends to occur in areas that have been damaged or inflamed.

Central Nervous System Part of the vertebrate nervous system comprising the brain and spinal cord.

Central Venous Catheter A catheter placed into the large vein in the neck, chest or groin.

Cephalalgia Pain in the head, a headache.

Cephalic Relating to the head.

Ceramide Oligosides Oligosides with an N-acetyl-sphingosine moiety.

Cercariae A free-swimming larva of the parasitic schistosome worm that has a tail and suckers on its head for penetration into a host.

Cerebral Embolism A blockage of blood flow through a vessel in the brain by a blood clot that formed elsewhere in the body and travelled to the brain.

Cerebral Ischaemia Is the localized reduction of blood flow to the brain or parts of the brain due to arterial obstruction or systematic hyperfusion.

Cerebral Infarction Is the ischemic kind of stroke due to a disturbance in the blood vessels supplying blood to the brain.

Cerebral Tonic Substance that can alleviate poor concentration and memory, restlessness, uneasiness and insomnia.

Cerebrosides Are glycosphingolipids which are important components in animal muscle and nerve cell membranes.

Cerebrovascular Disease Is a group of brain dysfunctions related to disease of the blood vessels supplying the brain.

Cerumen Ear wax, a yellowish waxy substance secreted in the ear canal of humans and other mammals.

cFLIP Cellular FLICE-inhibitory protein, an inhibitor of death ligand-induced apoptosis.

cGMP Cyclic guanosine monophosphate is a cyclic nucleotide derived from guanosine triphosphate (GTP). cGMP is a common regulator of ion channel conductance, glycogenolysis and cellular apoptosis. It also relaxes smooth muscle tissues.

CGRP Calcitonin Gene-Related Peptide A vasodilator neuropeptide that is expressed in a subgroup of small neurons in the dorsal root, trigeminal and vagal ganglia. This neuropeptide has been postulated to play a role in the pathophysiology of migraine.

Chalcones A subgroup of flavonoids.

Chancere A painless lesion formed during the primary stage of syphilis.

Chemoembolization A procedure in which the blood supply to the tumour is blocked surgically or mechanically and anticancer drugs are administered directly into the tumour.

Chemokines Are chemotactic cytokines, which stimulate migration of inflammatory cells towards tissue sites of inflammation.

Chemonociceptors Nociceptors or sensory peripheral neurons that are sensitive to chemical stimuli.

Chemosensitizer A drug that makes tumour cells more sensitive to the effects of chemotherapy.

Chemosis Oedema of the conjunctiva of the eye.

Chickenpox Is also known as varicella and is a highly contagious illness caused by primary infection with varicella zoster virus (VZV). The virus causes red, itchy bumps on the body.

Chilblains Small, itchy, painful lumps that develop on the skin. They develop as an abnormal response to cold. Also called perniosis or blain.

Chlorosis Iron deficiency anaemia characterized by greenish yellow colour.

- Cholagogue** Is a medicinal agent which promotes the discharge of bile from the system.
- Cholecalciferol** A form of vitamin D, also called vitamin D3. See Vitamin D.
- Cholecyst** Gall bladder.
- Cholecystitis** Inflammation of the gall bladder.
- Cholecystokinin** A peptide hormone that plays a key role in facilitating digestion in the small intestine.
- Cholera** An infectious gastroenteritis caused by enterotoxin-producing strains of the bacterium *Vibrio cholera* and characterized by severe, watery diarrhoea.
- Choleretic** Stimulation of the production of bile by the liver.
- Cholestasis** A condition caused by rapidly developing (acute) or long-term (chronic) interruption in the excretion of bile from the liver to the duodenum.
- Cholesterol** A soft, waxy, steroid substance found among the lipids (fats) in the bloodstream and in all our body's cells.
- Cholethiasis** Presence of gall stones (calculi) in the gall bladder.
- Choline** A water-soluble, organic compound, usually grouped within the vitamin B complex. It is an essential nutrient and is needed for physiological functions such as structural integrity and signalling roles for cell membranes, cholinergic neurotransmission (acetylcholine synthesis).
- Cholinergic** Activated by or capable of liberating acetylcholine, especially in the parasympathetic nervous system.
- Cholinergic System** A system of nerve cells that uses acetylcholine in transmitting nerve impulses.
- Cholinomimetic** Having an action similar to that of acetylcholine. Also called parasympathomimetic.
- Chronotropic** Affecting the time or rate, as the rate of contraction of the heart.
- Choriocarcinoma** A quick-growing malignant, trophoblastic, aggressive cancer that occurs in a woman's uterus (womb).
- Chromium (Cr)** Is required in trace amounts in humans for sugar and lipid metabolism. Its deficiency may cause a disease called chromium deficiency. It is found in cereals, legumes, nuts and animal sources.
- Chromoblastomycosis** A chronic fungal infection of the skin and the subcutaneous tissue caused by traumatic inoculation of a specific group of dematiaceous fungi (such as *Fonsecaea pedrosoi*, *Phialophora verrucosa*, *Fonsecaea compacta*) through the skin.
- Chromosome** Long pieces of DNA found in the centre (nucleus) of cells.
- Chronic** Persisting over extended periods.
- Chronic Obstructive Pulmonary Disease (COPD)** A progressive disease that makes it hard to breathe.
- Chronic Venous Insufficiency (CVI)** A medical condition where the veins cannot pump enough oxygen-poor blood back to the heart.
- Chyle** A milky bodily fluid consisting of lymph and emulsified fats or free fatty acids.
- Chylomicrons** Are large lipoprotein particles that transport dietary lipids from the intestines to other locations in the body. Chylomicrons are one of the five major groups of lipoproteins (chylomicrons, VLDL, IDL, LDL, HDL) that enable fats and cholesterol to move within the water-based solution of the bloodstream.
- Chylorus** Milky (having fat emulsion).
- Chyluria** Also called chylous urine, is a medical condition involving the presence of chyle (emulsified fat) in the urine stream, which results in urine appearing milky.
- Chymase** Member of the family of serine proteases found primarily in mast cell.
- Chymopapain** An enzyme derived from papaya, used in medicine and to tenderize meat.
- Cicatrizant** The term used to describe a product that promotes healing through the formation of scar tissue.
- C-Kit Receptor** A protein-tyrosine kinase receptor that is specific for stem cell factor. This interaction is crucial for the development of haematopoietic, gonadal and pigment stem cells.
- Cirrhosis** Chronic liver disease characterized by replacement of liver tissue by fibrous scar tissue and regenerative nodules/lumps leading progressively to loss of liver function.

- Clastogen** Is an agent that can cause one of two types of structural changes and breaks in chromosomes that result in the gain, loss or rearrangements of chromosomal segments. *Adj.* clastogenic.
- Claudication** Limping, impairment in walking.
- Climacterium** Refers to menopause and the bodily and mental changes associated with it.
- Clonic Seizures** Consist of rhythmic jerking movements of the arms and legs, sometimes on both sides of the body.
- Clonus** A series of involuntary muscular contractions and relaxations.
- Clyster** Enema.
- C-Myc** Codes for a protein that binds to the DNA of other genes and is therefore a transcription factor.
- CNS Depressant** Anything that depresses, or slows, the sympathetic impulses of the central nervous system (i.e. respiratory rate, heart rate).
- Coagulopathy** A defect in the body's mechanism for blood clotting, causing susceptibility to bleeding.
- Cobalamin** Vitamin B12. See Vitamin B12.
- Cocarcinogen** A chemical that promotes the effects of a carcinogen in the production of cancer.
- Cold** An acute inflammation of the mucous membrane of the respiratory tract especially of the nose and throat caused by a virus and accompanied by sneezing and coughing.
- Collagen** Protein that is the major constituent of cartilage and other connective tissue; comprises the amino acids hydroxyproline, proline, glycine and hydroxylysine.
- Collagenases** Enzymes that break the peptide bonds in collagen.
- Colic** A broad term which refers to episodes of uncontrollable, extended crying in a baby who is otherwise healthy and well fed.
- Colitis** Inflammatory bowel disease affecting the tissue that lines the gastrointestinal system.
- Collyrium** A lotion or liquid wash used as a cleanser for the eyes, particularly in diseases of the eye.
- Colorectal** Relating to the colon or rectum.
- Coma** A state of unconsciousness from which a patient cannot be aroused.
- Comedone** A blocked, open sebaceous gland where the secretions oxidize, turning black. Also called blackhead.
- Comitogen** Agent that is considered not to induce cell growth alone but to promote the effect of the mitogen.
- Concoction** A combination of crude ingredients that is prepared or cooked together.
- Condyloma, Condylomata Acuminata** Genital warts, venereal warts, anal wart or anogenital wart, a highly contagious sexually transmitted infection caused by epidermotropic human papillomavirus (HPV).
- Conglutination** Becoming stuck together.
- Conjunctival Hyperaemia** Enlarged blood vessels in the eyes.
- Conjunctivitis** Sore, red and sticky eyes caused by eye infection.
- Constipation** A very common gastrointestinal disorder characterized by the passing of hard, dry bowel motions (stools) and difficulty of bowel motion.
- Constitutive Androstane Receptor (CAR, NR113)** Is a nuclear receptor transcription factor that regulates drug metabolism and homeostasis.
- Consumption** Term used to describe wasting of tissues including but not limited to tuberculosis.
- Consumptive** Afflicted with or associated with pulmonary tuberculosis.
- Contraceptive** An agent that reduces the likelihood of or prevents conception.
- Contraindication** A condition which makes a particular treatment or procedure inadvisable.
- Contralateral Muscle** Muscle of opposite limb (leg or arm).
- Contralateral Rotation** Rotation occurring or originating in a corresponding part on an opposite side.
- Contusion** Another term for a bruise. A bruise, or contusion, is caused when blood vessels are damaged or broken as the result of a blow to the skin.
- Convulsant** A drug or physical disturbance that induces convulsion.

- Convulsion** Rapid and uncontrollable shaking of the body.
- Coolant** That which reduces body temperature.
- Copper (Cu)** Is essential in all plants and animals. It is found in a variety of enzymes, including the copper centres of cytochrome C oxidase and the enzyme superoxide dismutase (containing copper and zinc). In addition to its enzymatic roles, copper is used for biological electron transport. Because of its role in facilitating iron uptake, copper deficiency can often produce anaemia-like symptoms. Dietary sources include curry powder, mushroom, nuts, seeds, wheat germ, whole grains and animal meat.
- Copulation** To engage in coitus or sexual intercourse. *Adj.* copulatory.
- Cordial** A preparation that is stimulating to the heart.
- Corn** Or callus is a patch of hard, thickened skin on the foot that is formed in response to pressure or friction.
- Corpora Lutea** A yellow, progesterone-secreting body that forms from an ovarian follicle after the release of a mature egg.
- Corticosteroids** A class of steroid hormones that are produced in the adrenal cortex, used clinically for hormone replacement therapy, for suppressing ACTH secretion, for suppression of immune response and as antineoplastic, anti-allergic and antiinflammatory agents.
- Corticosterone** A 21-carbon steroid hormone of the corticosteroid type produced in the cortex of the adrenal glands.
- Cortisol** Is a corticosteroid hormone made by the adrenal glands.
- Cornification** Is the process of forming an epidermal barrier in stratified squamous epithelial tissue.
- Coryza** A word describing the symptoms of a head cold. It describes the inflammation of the mucus membranes lining the nasal cavity which usually gives rise to the symptoms of nasal congestion and loss of smell, among other symptoms.
- COX-1** See Cyclooxygenase-1.
- COX-2** See Cyclooxygenase-2.
- CpG Islands** Genomic regions that contain a high frequency of CpG sites.
- CpG Sites** The cytosine-phosphate-guanine nucleotide that links two nucleosides together in DNA.
- cPLA(2)** Cytosolic phospholipases A2; these phospholipases are involved in cell signalling processes, such as inflammatory response.
- CPY1B1, CPY1A1** A member of the cytochrome P450 superfamily of heme-thiolate monooxygenase enzymes.
- Corticosterone** A 21-carbon corticosteroid hormone produced in the cortex of the adrenal glands that functions in the metabolism of carbohydrates and proteins.
- Creatine** A nitrogenous organic acid that occurs naturally in vertebrates and helps to supply energy to muscle.
- Creatine Hosphokinase (CPK, CK)** Enzyme that catalyzes the conversion of creatine and consumes adenosine triphosphate (ATP) to create phosphocreatine and adenosine diphosphate (ADP).
- CREB** cAMP response element binding, a protein that is a transcription factor that binds to certain DNA sequences called cAMP response elements.
- Crohn's Disease** An inflammatory disease of the intestines that affect any part of the gastrointestinal tract.
- Crossover Study** A longitudinal, balance study in which participants receive a sequence of different treatments or exposures.
- Croup** Is an infection of the throat (larynx) and windpipe (trachea) that is caused by a virus. Also called laryngotracheobronchitis.
- Cryptococcal Meningitis** A fungal infection of the membranes covering the brain and spinal cord (meninges).
- Cryptorchidism (Cryptorchism)** A developmental defect characterized by the failure of one or both testes to move into the scrotum as the male foetus develops.
- Curettage** Surgical procedure in which a body cavity or tissue is scraped with a sharp instrument or aspirated with a cannula.
- Cutaneous** Pertaining to the skin.
- CXC8** Also known as interleukin 8, IL-8.
- Cyanogenesis** Generation of cyanide. *Adj.* cyanogenetic.

- Cyclooxygenase (COX)** An enzyme that is responsible for the formation of prostanoids—prostaglandins, prostacyclins and thromboxanes that are each involved in the inflammatory response. Two different COX enzymes existed, now known as COX-1 and COX-2.
- Cyclooxygenase-1 (COX-1)** Is known to be present in most tissues. In the gastrointestinal tract, COX-1 maintains the normal lining of the stomach. The enzyme is also involved in kidney and platelet function.
- Cyclooxygenase-2 (COX-2)** Is primarily present at sites of inflammation.
- Cysteine Proteases** Are enzymes that degrade polypeptides possessing a common catalytic mechanism that involves a nucleophilic cysteine thiol in a catalytic triad. They are found in fruits like papaya, pineapple and kiwifruit.
- Cystitis** A common urinary tract infection that occurs when bacteria travel up the urethra, infect the urine and inflame the bladder lining.
- Cystorrhoea** Discharge of mucus from the bladder.
- Cytochrome bc-1 Complex** Ubihydroquinone: cytochrome c oxidoreductase.
- Cytochrome P450 3A CYP3A** A very large and diverse superfamily of heme-thiolate proteins found in all domains of life. This group of enzymes catalyzes many reactions involved in drug metabolism and synthesis of cholesterol, steroids and other lipids.
- Cytokine** Non-antibody proteins secreted by certain cells of the immune system which carry signals locally between cells. They are a category of signalling molecules that are used extensively in cellular communication.
- Cytopathic** Any detectable, degenerative changes in the host cell due to infection.
- Cytoprotective** Protecting cells from noxious chemicals or other stimuli.
- Cytosolic** Relates to the fluid of the cytoplasm in cells.
- Cytostatic** Preventing the growth and proliferation of cells.
- Cytotoxic** Of or relating to substances that are toxic to cells, cell-killing.
- D-Galactosamine** An amino sugar with unique hepatotoxic properties in animals.
- Dandruff** Scurf, dead, scaly skin among the hair.
- Dartre** Condition of dry, scaly skin.
- Debility** Weakness, relaxation of muscular fibre.
- Debridement** Is the process of removing non-living tissue from pressure ulcers, burns and other wounds.
- Debriding Agent** Substance that cleans and treats certain types of wounds, burns and ulcers.
- Deciduogenic** Relating to the uterus lining that is shed off at childbirth.
- Deciduoma** Decidual tissue induced in the uterus (as by trauma) in the absence of pregnancy.
- Deciduomata** Plural of deciduoma.
- Decidual Stromal Cells** Like endometrial glands and endothelium, express integrins that bind basement components.
- Decoction** A medical preparation made by boiling the ingredients.
- Decongestant** A substance that relieves or reduces nasal or bronchial congestion.
- Deep Venous Thrombosis** Is a blood clot that forms in a vein deep inside a part of the body.
- Defibrinated Plasma** Blood whose plasma component has had fibrinogen and fibrin removed.
- Degranulation** Cellular process that releases antimicrobial cytotoxic molecules from secretory vesicles called granules found inside some cells.
- DelayedAfterdepolarizations(DADs)** Abnormal depolarization that begins during phase 4, after repolarization is completed but before another action potential would normally occur.
- Delirium** Is common, sudden severe confusion and rapid changes in brain function that occur with physical or mental illness; it is reversible and temporary.
- Demulcent** An agent that soothes internal membranes. Also called emollient.
- Dendritic Cells** Are immune cells and form part of the mammalian immune system, functioning as antigen presenting cells.
- Dentition** A term that describes all of the upper and lower teeth collectively.
- Deobstruent** A medicine which removes obstructions. Also called an aperient.

- Deoxyypyridinoline (DPD)** A cross-link product of collagen molecules found in bone and excreted in urine during bone degradation.
- Depilatory** An agent for removing or destroying hair.
- Depressant** A substance that diminish functional activity, usually by depressing the nervous system.
- Depurative** An agent used to cleanse or purify the blood; it eliminates toxins and purifies the system.
- Dermatitis** Inflammation of the skin causing discomfort such as eczema.
- Dermatitis Herpetiformis** An autoimmune chronic blistering skin disorder characterized by blisters filled with a watery fluid.
- Dermatophyte** A fungus parasitic on the skin.
- Dermatosis** Is a broad term that refers to any disease of the skin, especially one that is not accompanied by inflammation.
- Dermonecrotic** Pertaining to or causing necrosis of the skin.
- Desquamation** The shedding of the outer layers of the skin.
- Desquamative Gingivitis** Red, painful, glazed and friable gingivae which may be a manifestation of some mucocutaneous conditions such as lichen planus or the vesiculobullous disorders.
- Detoxifier** A substance that promotes the removal of toxins from a system or organ.
- Diabetes** A metabolic disorder associated with inadequate secretion or utilization of insulin and characterized by frequent urination and persistent thirst. See Diabetes mellitus.
- Diabetes Mellitus (DM)** Sometimes called 'sugar diabetes' is a set of chronic, metabolic disease conditions characterized by high blood sugar (glucose) levels that result from defects in insulin secretion, or action, or both. Diabetes mellitus appears in two forms.
- Diabetes Mellitus Type I** Formerly known as juvenile onset diabetes, it is caused by deficiency of the pancreatic hormone insulin as a result of destruction of insulin-producing beta cells of the pancreas. Lack of insulin causes an increase of fasting blood glucose that begins to appear in the urine above the renal threshold.
- Diabetes Mellitus Type II** Formerly called non-insulin-dependent diabetes mellitus or adult-onset diabetes, the disorder is characterized by high blood glucose in the context of insulin resistance and relative insulin deficiency in which insulin is available but cannot be properly utilized.
- Diabetic Neuropathy** A neuropathic disorder that is associated with diabetes mellitus. It affects all peripheral nerves including pain fibres, motor neurons and the autonomic nervous system.
- Diabetic Retinopathy** Damage to the retina caused by complications of diabetes mellitus, which can eventually lead to blindness.
- Dialysis** Is a method of removing toxic substances (impurities or wastes) from the blood when the kidneys are unable to do so.
- Diaphoresis** Is profuse sweating commonly associated with shock and other medical emergency conditions.
- Diaphoretic** A substance that induces perspiration. Also called sudorific.
- Diaphyseal** Pertaining to or affecting the shaft of a long bone (diaphysis).
- Diaphysis** The main or midsection (shaft) of a long bone.
- Diarrhoea** A profuse, frequent and loose discharge from the bowels.
- Diastolic** Referring to the time when the heart is in a period of relaxation and dilatation (expansion). *Cf.* systolic.
- Dieresis** Surgical separation of parts.
- Dietary Fibre** Is a term that refers to a group of food components that pass through the stomach and small intestine undigested and reach the large intestine virtually unchanged. Scientific evidence suggests that a diet high in dietary fibre can be of value for treating or preventing such disorders as constipation, irritable bowel syndrome, diverticular disease, hiatus hernia and haemorrhoids. Some components of dietary fibre may also be of value in reducing the level of cholesterol in blood and thereby decreasing a risk factor for coronary heart disease and the development of gallstones. Dietary fibre is beneficial in the treatment of some diabetics.

- Digalactosyl Diglycerides** Are the major lipid components of chloroplasts.
- Diosgenin** A steroid-like substance that is involved in the production of the hormone progesterone, extracted from roots of *Dioscorea* yam.
- Dipsia** Sensation of dryness in the mouth and throat related to a desire to drink.
- Dipsomania** Pathological use of alcohol.
- Discutient** An agent (as a medicinal application) which serves to disperse morbid matter.
- Disinfectant** An agent that prevents the spread of infection, bacteria or communicable disease.
- Distal Sensory Polyneuropathy (DSPN)** Or peripheral neuropathy is the most common neurological problem in HIV disease. DSPN also represents a complex symptom that occurs because of peripheral nerve damage related to advanced HIV disease.
- Diuresis** Increased urination.
- Diuretic** A substance that increases urination (diuresis).
- Diverticular Disease** Is a condition affecting the large bowel or colon and is thought to be caused by eating too little fibre.
- DMBA** 7,12-Dimethylbenzanthracene. A polycyclic aromatic hydrocarbon found in tobacco smoke that is a potent carcinogen.
- DNA** Deoxyribonucleic acid. A nucleic acid that contains the genetic instructions used in the development and functioning of all known living organisms.
- DOCA** Deoxycorticosterone acetate. A steroid chemical used as replacement therapy in Addison's disease.
- Dopamine** A catecholamine neurotransmitter that occurs in a wide variety of animals, including both vertebrates and invertebrates.
- Dopaminergic** Relating to or activated by the neurotransmitter, dopamine.
- Double Blind** Refer to a clinical trial or experiment in which neither the subject nor the researcher knows which treatment any particular subject is receiving.
- Douche** A localized spray of liquid directed into a body cavity or onto a part.
- DPPH** 2,2-Diphenyl-1-picryl-hydrazyl. A crystalline, stable free radical used as an inhibitor of free radical reactions.
- Dracunculiasis** Also called guinea worm disease (GWD), is a parasitic infection caused by the nematode, *Dracunculus medinensis*.
- Dropsy** An old term for the swelling of soft tissues due to the accumulation of excess water. *Adj.* dropsical.
- Drug-Metabolizing Enzymes** Play central roles in the biotransformation, metabolism and/or detoxification of xenobiotics or foreign compounds that are introduced to the human body.
- Drusen** Tiny yellow or white deposits of extracellular materials in the retina of the eye or on the optic nerve head.
- DT-Diaphorase** Also called DTD or NAD(P) H:quinone oxidoreductase, is an obligate two-electron reductase which bioactivates chemotherapeutic quinones.
- Dyads** Two adjacent structural units in a polymer molecule.
- Dysaesthesia** An unpleasant abnormal sensation produced by normal stimuli.
- Dysentery** Formerly known as flux or the bloody flux, is a disorder of the digestive system that results in severe diarrhoea containing mucus and blood in the faeces. It is caused usually by a bacterium called *Shigella*.
- Dysgeusia** Distortion of the sense of taste.
- Dyshomeostasis** An imbalance or other breakdown of a homeostasis system.
- Dyskinesia** The impairment of the power of voluntary movement, resulting in fragmentary or incomplete movements. *Adj.* dyskinetic.
- Dyslipidaemia** Abnormality in or abnormal amount of lipids and lipoproteins in the blood.
- Dysmenorrhoea** Is a menstrual condition characterized by severe and frequent menstrual cramps and pain associated with menstruation.
- Dysmotility Syndrome** A vague, descriptive term used to describe diseases of the muscles of the gastrointestinal tract (oesophagus, stomach, small and large intestines).
- Dyspareunia** Painful sexual intercourse.
- Dyspeidia** Indigestion followed by nausea.
- Dyspepsia** Refers to a symptom complex of epigastric pain or discomfort. It is often defined as chronic or recurrent discomfort centred in the upper abdomen and can be caused by a variety of conditions. *Cf.* functional dyspepsia.

Dysphagia Swallowing disorder.

Dysphonia A voice disorder and an impairment in the ability to produce voice sounds using the vocal organs.

Dysplasia Refers to abnormality in development.

Dyspnoea Shortness of breath; difficulty in breathing.

Dysrhythmias See Arrhythmias.

Dystocia Abnormal or difficult childbirth or labour.

Dystonia A neurological movement disorder characterized by prolonged, repetitive muscle contractions that may cause twisting or jerking movements of muscles.

Dysuria Refers to difficult and painful urination.

E-Selectin Also known as endothelial leukocyte adhesion molecule-1 (ELAM-1), CD62E, a member of the selectin family. It is transiently expressed on vascular endothelial cells in response to IL-1 beta and TNF-alpha.

EC 50 Median effective concentration that produces desired effects in 50 % of the test population.

Ecbolic A drug (as an ergot alkaloid) that tends to increase uterine contractions and that is used especially to facilitate delivery.

Ecchymosis Skin discoloration caused by the escape of blood into the tissues from ruptured blood vessels.

ECG See Electrocardiography.

EC-SOD Extracellular superoxide dismutase. A tissue enzyme mainly found in the extracellular matrix of tissues. It participates in the detoxification of reactive oxygen species by catalyzing the dismutation of superoxide radicals.

Ectopic Heartbeats Small changes in an otherwise normal heartbeat that lead to extra or skipped heartbeats.

Ectrodactyly Involves the absence of one or more central digits of the hand or foot.

Eczema Is broadly applied to a range of persistent skin conditions. These include dryness and recurring skin rashes which are characterized by one or more of these symptoms: redness, skin oedema, itching and dryness, crusting, flaking, blistering, cracking, oozing or bleeding.

Eczematous Rash Dry, scaly, itchy rash.

ED 50 Is defined as the dose producing a response that is 50 % of the maximum obtainable.

EGFR Proteins Epidermal growth factor receptor (EGFR) proteins. Protein kinases are enzymes that transfer a phosphate group from a phosphate donor onto an acceptor amino acid in a substrate protein.

EGR-1 Early growth response 1, a human gene.

Eicosanoids Are signalling molecules made by oxygenation of arachidonic acid, a 20-carbon essential fatty acid, includes prostaglandins and related compounds.

Elastase A serine protease that also hydrolyzes amides and esters.

Electrocardiography Or ECG is a transthoracic interpretation of the electrical activity of the heart over time captured and externally recorded by skin electrodes.

Electromyogram (EMG) A test used to record the electrical activity of muscles. An electromyogram (EMG) is also called a myogram.

Electuary A medicinal paste composed of powders, or other medical ingredients, incorporated with sweeteners to hide the taste, suitable for oral administration.

Elephantiasis A disorder characterized by chronic thickened and oedematous tissue on the genitals and legs due to various causes.

Embrocation Lotion or liniment that relieves muscle or joint pains.

Embryonation Formation of embryo in the egg.

Embryotoxic Term that describes any chemical which is harmful to an embryo.

Emesis Vomiting, throwing up.

Emetic An agent that induces vomiting. *Cf.* antiemetic.

Emetocathartic Causing vomiting and purging.

Emmenagogue A substance that stimulates, initiates and/or promotes menstrual flow. Emmenagogues are used in herbal medicine to balance and restore the normal function of the female reproductive system.

Emollient An agent that has a protective and soothing action on the surfaces of the skin and membranes.

- Emphysema** A long-term, progressive disease of the lungs that primarily causes shortness of breath.
- Emulsion** A preparation formed by the suspension of very finely divided oily or resinous liquid in another liquid.
- Encephalitis** Inflammation of the brain.
- Encephalocele** Protrusion of brain tissue through a congenital fissure in the skull.
- Encephalomalacia** Cerebral softening, a localized softening of the brain substance, due to haemorrhage or inflammation.
- Encephalopathy** A disorder or disease of the brain.
- Endocrine** *Adj.* of or relating to endocrine glands or the hormones secreted by them.
- Endocytosis** Is the process by which cells absorb material (molecules such as proteins) from outside the cell by engulfing it with their cell membrane.
- Endometrial Cancer** Cancer that arises in the endometrium, the lining of the uterus (womb).
- Endometriosis** Is a common and often painful disorder of the female reproductive system in which the endometrium, the tissue that normally lines the womb (uterus), grows outside the uterus. The two most common symptoms of endometriosis are pain and infertility.
- Endometritis** Refers to inflammation of the endometrium, the inner lining of the uterus.
- Endometrium** The inner lining of the uterus.
- Endoplasmic Reticulum** Is a network of tubules, vesicles and sacs around the nucleus that are interconnected.
- Endostatin** A naturally occurring 20-kDa C-terminal protein fragment derived from type XVIII collagen. It is reported to serve as an anti-angiogenic agent that inhibits the formation of the blood vessels that feed cancer tumours.
- Endosteum** The thin layer of cells lining the medullary cavity of a bone.
- Endosteal** Pertaining to the endosteum.
- Endothelial Progenitor Cells** Population of rare cells that circulate in the blood with the ability to differentiate into endothelial cells, the cells that make up the lining of blood vessels.
- Endothelin** Any of a group of vasoconstrictive peptides produced by endothelial cells that constrict blood vessels and raise blood pressure.
- Endotoxemia** The presence of endotoxins in the blood, which may result in shock. *Adj.* endotoxemic.
- Endotoxin** Toxins associated with certain bacteria, unlike an 'exotoxin' that is not secreted in soluble form by live bacteria, but is a structural component in the bacteria which is released mainly when bacteria are lysed.
- Enema** Liquid injected into the rectum either as a purgative or medicine. Also called clyster.
- Enophthalmos** A condition in which the eye falls back into the socket and inhibits proper eyelid function.
- Enteral** Term used to describe the intestines or other parts of the digestive tract.
- Enteralgia** Pain in the intestines; intestinal colic.
- Enteral Administration** Involves the oesophagus, stomach and small and large intestines (i.e. the gastrointestinal tract).
- Enteritis** Refers to inflammation of the small intestine.
- Enterocolic Disorder** Inflamed bowel disease.
- Enterocytes** Tall columnar cells in the small intestinal mucosa that are responsible for the final digestion and absorption of nutrients.
- Enterohaemorrhagic** Causing bloody diarrhoea and colitis, said of pathogenic microorganisms.
- Enterohepatonephropathy** Hepatorenal lesions accompanied by renal failure.
- Enterolactone** A lignin formed by the action of intestinal bacteria on lignan precursors found in plants; acts as a phytoestrogen.
- Enteropooling** Increased fluids and electrolytes within the lumen of the intestines due to increased levels of prostaglandins.
- Enterotoxigenic** Of or being an organism containing or producing an enterotoxin.
- Enterotoxin** Is a protein toxin released by a microorganism in the intestine.
- Entheogen** A substance taken to induce a spiritual experience.
- Enuresis** Bed-wetting, a disorder of elimination that involves the voluntary or involuntary

release of urine into bedding, clothing or other inappropriate places.

Envenomation Is the entry of venom into a person's body, and it may cause localized or systemic poisoning.

Eosinophilia The state of having a high concentration of eosinophils (eosinophil granulocytes) in the blood.

Eosinophils Or, less commonly, acidophils, are white blood cells that are one of the immune system components.

Epidermal Growth Factor Receptor (EGFR) Belongs to the ErbB family of receptor tyrosine kinases (RTK). EGFR are involved in the pathogenesis and progression of different carcinoma types.

Epididymis A structure within the scrotum attached to the backside of the testis and whose coiled duct provides storage, transit and maturation of spermatozoa.

Epididymitis A medical condition in which there is inflammation of the epididymis.

Epigastralgia Pain in the epigastric region.

Epigastric Discomfort Bloating abdomen, swelling of abdomen and abdominal distension.

Epilepsy A common chronic neurological disorder that is characterized by recurrent unprovoked seizures.

Epileptiform Resembling epilepsy or its manifestations. *Adj.* epileptiformic.

Epileptogenesis A process by which a normal brain develops epilepsy, a chronic condition in which seizures occur. *Adj.* epileptogenic.

Episiotomy A surgical incision through the perineum made to enlarge the vagina and assist childbirth.

Epithelioma A usually benign skin disease most commonly occurring on the face, around the eyelids and on the scalp.

Epitope A single antigenic site on a protein against which an antibody reacts.

Epitrochlearis The superficial-most muscle of the arm anterior surface.

Epistaxis Acute haemorrhage from the nostril, nasal cavity or nasopharynx (nosebleed).

Epstein-Barr Virus Herpes virus that is the causative agent of infectious mononucleosis.

It is also associated with various types of human cancers.

ERbeta Oestrogen receptor beta. A nuclear receptor which is activated by the sex hormone, oestrogen.

Ergocalciferol A form of vitamin D. Also called vitamin D2. See Vitamin D.

Ergonic Increasing capacity for bodily or mental labour, especially by eliminating fatigue symptoms.

ERK (Extracellular Signal-Regulated Kinases) Widely expressed protein kinase intracellular signalling molecules which are involved in functions including the regulation of meiosis, mitosis and postmitotic functions in differentiated cells.

Eructation The act of belching or of casting up wind from the stomach through the mouth.

Eruption A visible rash or cutaneous disruption.

Erysipelas Is an intensely red *Streptococcus* bacterial infection that occurs on the face and lower extremities.

Erythema Abnormal redness and inflammation of the skin, due to vasodilation.

Erythema Multiforme Is a skin disorder due to an allergic reaction or infection; it is characterized by fever, general ill feeling, skin itching, joint aches and multiple skin lesions.

Erythematous Characterized by erythema.

Erythroleukoplakia An abnormal patch of red and white tissue that forms on mucous membranes in the mouth and may become cancer. Tobacco (smoking and chewing) and alcohol may increase the risk of erythroleukoplakia.

Erythropoietin (EPO) A hormone produced by the kidney that promotes the formation of red blood cells (erythrocytes) in the bone marrow.

Eschar A slough or piece of dead tissue that is cast off from the surface of the skin.

Escharotic Capable of producing an eschar; a caustic or corrosive agent.

Estradiol Is the predominant sex hormone present in females. Also called oestradiol.

Euglycaemia Normal blood glucose concentration.

Eupeptic Conducive to digestion.

- Exanthematous** Characterized by or of the nature of an eruption or rash.
- Excitotoxicity** Is the pathological process by which neurons are damaged and killed by glutamate and similar substances.
- Excipient** A pharmacologically inert substance used as a diluent or vehicle for the active ingredients of a medication.
- Exfoliative Cheilitis** Is a reactive process, in which upper, lower or both lips become chronically inflamed, crusted and sometimes fissured.
- Exocytosis** The cellular process by which cells excrete waste products or chemical transmitters.
- Exophthalmos or Exophthalmia or Proptosis** Is a bulging of the eye anteriorly out of the orbit. *Adj.* exophthalmic.
- Exotoxin** A toxin secreted by a microorganism and released into the medium in which it grows.
- Expectorant** An agent that increases bronchial mucous secretion by promoting liquefaction of the sticky mucous and expelling it from the body.
- Exteroceptive** Responsiveness to stimuli that are external to an organism.
- Extrapyramidal Side Effects** Are a group of symptoms (tremor, slurred speech, akathisia, dystonia, anxiety, paranoia and bradyphrenia) that can occur in persons taking antipsychotic medications.
- Extravasation** Discharge or escape, as of blood from the vein into the surrounding tissues; discharge or escape from a vessel or channel.
- Fabry Disease** Is a rare X-linked (inherited) lysosomal storage disease caused by alpha-galactosidase A deficiency, which can cause a wide range of systemic symptoms such as pain in the extremities, papules on the lower body parts, cornea clouding, fatigue, neuropathy and renal and cardiac complications.
- FAC Chemotherapy** Fluorouracil, doxorubicin (adriamycin) and cyclophosphamide chemotherapy.
- FADD** Fas-associated protein with death domain, the protein encoded by this gene is an adaptor molecule which interacts with other death cell surface receptors and mediates apoptotic signals.
- Familial Adenomatous Polyposis (FAP)** Is an inherited condition in which numerous polyps form mainly in the epithelium of the large intestine.
- Familial Amyloid Polyneuropathy (FAP)** Also called Corino de Andrade's disease, a neurodegenerative autosomal dominant genetically transmitted, fatal, incurable disease.
- Familial Dysautonomia** A genetic disorder that affects the development and survival of autonomic and sensory nerve cells.
- Fanconi Syndrome** Is a disease of the proximal renal tubes which certain substances normally absorbed into the bloodstream by the kidneys are released into the urine instead.
- FasL or CD95L** Fas ligand is a type-II transmembrane protein that belongs to the tumour necrosis factor (TNF) family.
- FAS Fatty Acid Synthase (FAS)** A multi-enzyme that plays a key role in fatty acid synthesis.
- Fas Molecule** A member of the tumour necrosis factor receptors that mediates apoptotic signal in many cell types.
- Fauces** The passage leading from the back of the mouth into the pharynx.
- Favus** A chronic skin infection, usually of the scalp, caused by the fungus, *Trichophyton schoenleinii*, and characterized by the development of thick, yellow crusts over the hair follicles. Also termed tinea favosa.
- Febrifuge** An agent that reduces fever. Also called an antipyretic.
- Febrile** Pertaining to or characterized by fever.
- Febrile Neutropenia** The development of fever, often with other signs of infection, in an individual with neutropenia, an abnormally low number of neutrophil granulocytes in the blood.
- Felon** A purulent infection in the bulbous distal end of a finger.
- Fetotoxic** Toxic to the foetus.
- Fibrates** Hypolipidemic agents primarily used for decreasing serum triglycerides while increasing high-density lipoprotein (HDL).
- Fibril** A small slender fibre or filament.

- Fibrin** Insoluble protein that forms the essential portion of the blood clot.
- Fibrinolysis** A normal ongoing process that dissolves fibrin and results in the removal of small blood clots.
- Fibrinolytic** Causing the dissolution of fibrin by enzymatic action.
- Fibroblast** Type of cell that synthesizes the extracellular matrix and collagen, the structural framework (stroma) for animal tissues, and plays a critical role in wound healing.
- Fibrogenic** Promoting the development of fibres.
- Fibromyalgia** A common and complex chronic, body-wide pain disorder that affects people physically, mentally and socially. Symptoms include debilitating fatigue, sleep disturbance, and joint stiffness. Also referred to as FM or FMS.
- Fibronectin** A high molecular weight (~440 kDa) glycoprotein of the extracellular matrix (ECM) that adheres to membrane-spanning receptor proteins called integrins.
- Fibrosarcoma** A malignant tumour derived from fibrous connective tissue and characterized by immature proliferating fibroblasts or undifferentiated anaplastic spindle cells.
- Fibrosis** The formation of fibrous tissue as a reparative or reactive process.
- Filarial** Pertaining to a threadlike nematode worm.
- Filariasis** A parasitic and infectious tropical disease that is caused by threadlike filarial nematode worms in the superfamily Filarioidea.
- Fistula** An abnormal connection between two organs inside of the body.
- Fistula-in-Ano** A track connecting the internal anal canal to the skin surrounding the anal orifice.
- 5'-Nucleotidase** 5'-Ribonucleotide phosphohydrolase. An intrinsic membrane glycoprotein present as an ectoenzyme in a wide variety of mammalian cells, hydrolyzes 5'-nucleotides to their corresponding nucleosides.
- Flatulence** Is the presence of a mixture of gases known as flatus in the digestive tract of mammals expelled from the rectum. Excessive flatulence can be caused by lactose intolerance, certain foods or a sudden switch to a high fibre.
- Flavans** A subgroup of flavonoids. See Flavonoids.
- Flavanols** A subgroup of flavonoids and are a class of flavonoids that use the 2-phenyl-3,4-dihydro-2H-chromen-3-ol skeleton. These compounds include the catechins and the catechin gallates. They are found in chocolate, fruits and vegetables. See Flavonoids.
- Flavanones** A subgroup of flavonoids and constitutes >90 % of total flavonoids in citrus. The major dietary flavanones are hesperetin, naringenin and eriodictyol.
- Flavivirus** A family of viruses transmitted by mosquitoes and ticks that cause some important diseases, including dengue, yellow fever, tick-borne encephalitis and West Nile fever.
- Flavones** A subgroup of flavonoids based on the backbone of 2-phenylchromen-4-one (2-phenyl-1-benzopyran-4-one). Flavones are mainly found in cereals and herbs.
- Flavonoids** Or bioflavonoids are a group of polyphenolic antioxidant compounds in that occur in plant as secondary metabolites. They are responsible for the colour of fruit and vegetables. Twelve basic classes (chemical types) of flavonoids have been recognized: flavones, isoflavones, flavans, flavanones, flavanols, flavanolols, anthocyanidins, catechins (including proanthocyanidins), leucoanthocyanidins, chalcones, dihydrochalcones and auronones. Apart from their antioxidant activity, flavonoids are known for their ability to strengthen capillary walls, thus assisting circulation and helping to prevent and treat bruising, varicose veins, bleeding gums and nosebleeds and heavy menstrual bleeding and are also antiinflammatory.
- Fluorine** F is an essential chemical element that is required for maintenance of healthy bones and teeth and to reduce tooth decay. It is found in sea weeds, tea, water, seafood and dairy products.
- Fluorosis** A dental health condition caused by a child receiving too much fluoride during tooth development.
- Flux** An excessive discharge of fluid.

- FMD (Flow-Mediated Dilation)** A measure of endothelial dysfunction which is used to evaluate cardiovascular risk. Also called FMVD (flow-mediated vasodilation).
- Focal Adhesion Kinase (FAK)** Is a protein tyrosine kinase which is recruited at an early stage to focal adhesions and which mediates many of the downstream regulatory responses.
- Follicle-Stimulating Hormone (FSH)** A hormone produced by the pituitary gland. In women, it helps control the menstrual cycle and the production of eggs by the ovaries.
- Follicular Atresia** The breakdown of the ovarian follicles.
- Fomentation** Treatment by the application of war, moist substance.
- Fontanelle** Soft spot on an infant's skull.
- Forkhead Box-O Transcription Factors (FOXOs)** Are a family of transcription factors that play important roles in regulating the expression of genes involved in cell growth, proliferation, differentiation and longevity. It also plays an important role in tumour suppression by regulating the expression of genes involved in stress resistance, DNA damage repair, cell cycle arrest and apoptosis.
- Framboesia** See Yaws.
- FRAP** Ferric reducing ability of plasma. An assay used to assess antioxidant property.
- Friedreich's Ataxia** Is a genetic inherited disorder that causes progressive damage to the nervous system resulting in symptoms ranging from muscle weakness and speech problems to heart disease. *Cf.* ataxia.
- Fulminant Hepatitis** Acute liver failure.
- Functional Dyspepsia** A non-ulcer condition that causes an upset stomach or pain or discomfort in the upper belly, near the ribs.
- Functional Food** Is any fresh or processed food claimed to have a health-promoting or disease-preventing property beyond the basic function of supplying nutrients. Also called medicinal food.
- Furuncle** Is a skin disease caused by the infection of hair follicles usually caused by *Staphylococcus aureus*, resulting in the localized accumulation of pus and dead tissue.
- Furunculosis** Skin condition characterized by persistent, recurring boils.
- GABA** Gamma aminobutyric acid, required as an inhibitory neurotransmitter to block the transmission of an impulse from one cell to another in the central nervous system, which prevents over-firing of the nerve cells. It is used to treat both epilepsy and hypertension.
- GADD 152** A pro-apoptotic gene.
- Galctifuge** Or lactifuge, causing the arrest of milk secretion.
- Galactagogue** A substance that promotes the flow of milk.
- Galactophoritis** Inflammation of the milk ducts.
- Galactopoietic** Increasing the flow of milk; milk producing.
- Gall Bladder** A small, pear-shaped muscular sac, located under the right lobe of the liver, in which bile secreted by the liver is stored until needed by the body for digestion. Also called cholecyst, cholecystitis.
- Gallic Acid Equivalent (GAE)** Measures the total phenol content in terms of the standard Gallic acid by the Folin–Ciocalteu assay.
- Galphai Proteins or G Alpha I Proteins** Are heterotrimeric guanine nucleotide-regulatory (G) proteins associated with a variety of intracellular membranes and specific plasma membrane domains.
- Gamma GT (GGT)** Gamma-glutamyl transpeptidase, a liver enzyme.
- Gastralgia (Heartburn)** Pain in the stomach or abdominal region. It is caused by excess of acid, or an accumulation of gas, in the stomach.
- Gastric** Pertaining to or affecting the stomach.
- Gastric Emptying** Refers to the speed at which food and drink leave the stomach.
- Gastritis** Inflammation of the stomach.
- Gastrocnemius Muscle** The big calf muscle at the rear of the lower leg.
- Gastroprokinetic** See Prokinetic.
- Gastrotonic (Gastroprotective)** Substance that strengthens, tones or regulates gastric functions (or protects from injury) without overt stimulation or depression.
- Gavage** Forced feeding.
- Gene Silencing** Suppression of the expression of a gene.

- Genotoxic** Describes a poisonous substance which harms an organism by damaging its DNA, thereby capable of causing mutations or cancer.
- Genotoxin** A chemical or other agent that damages cellular DNA, resulting in mutations or cancer.
- Geriatrics** Is a subspecialty of internal medicine that focuses on healthcare of elderly people.
- Gestational Hypertension** Development of arterial hypertension in a pregnant woman after 20 weeks gestation.
- Ghrelin** A gastrointestinal peptide hormone secreted by epithelial cells in the stomach lining; it stimulates appetite and gastric emptying and increases cardiac output.
- Gingival Index** An index describing the clinical severity of gingival inflammation as well as its location.
- Gingivitis** Refers to gingival inflammation induced by bacterial biofilms (also called plaque) adherent to tooth surfaces.
- Gin-nan Sitotoxism** Toxicity caused by ingestion of ginkgotoxin and characterized mainly by epileptic convulsions, paralysis of the legs and loss of consciousness.
- GIP** Gastric inhibitory polypeptide also known as the glucose-dependent insulinotropic peptide, a member of the secretin family of hormones.
- Glaucoma** A group of eye diseases in which the optic nerve at the back of the eye is slowly destroyed, leading to impaired vision and blindness.
- Gleet** A chronic inflammation (as gonorrhoea) of a bodily orifice usually accompanied by an abnormal discharge.
- Glial Cells** Support, non-neuronal cells in the central nervous system that maintain homeostasis, form myelin and provide protection for the brain's neurons.
- Glioma** Is a type of tumour that starts in the brain or spine. It is called a glioma because it arises from glial cells.
- Glioblastoma** Common and most lethal form of brain tumour.
- Glioblastoma Multiforme** Most common and most aggressive type of primary brain tumour in humans, involving glial cells.
- Glomerulonephritis (GN)** A renal disease characterized by inflammation of the glomeruli or small blood vessels in the kidneys. Also known as glomerular nephritis. *Adj.* glomerulonephritic.
- Glomerulosclerosis** A hardening (fibrosis) of the glomerulus in the kidney.
- Glossal** Pertaining to the tongue.
- GLP-1** Glucagon-like peptide-1.
- Glucagon-Like Peptide-1 (GLP-1)** Is derived from the transcription product of the proglucagon gene, reduces insulin requirement in diabetes mellitus and promotes satiety.
- Gluconeogenesis** A metabolic pathway that results in the generation of glucose from non-carbohydrate carbon substrates such as lactate. *Adj.* gluconeogenic.
- Glucose-6-phosphate Dehydrogenase (G6PD or G6PDH)** Is a cytosolic enzyme in the pentose phosphate metabolic pathway.
- Glucose Transporter Type 4 (GLUT 4)** Insulin-regulated glucose transporter found in adipose tissues and striated muscles that modulates insulin-related translocation into the cell.
- Glucose Transporters** GLUT or SLC2A family, are a family of membrane proteins found in most mammalian cells.
- Glucosuria or Glycosuria** Is the excretion of glucose into the urine.
- Glucosyltransferase** An enzyme that enables the transfer of glucose.
- Glucuronidation** A phase II detoxification pathway occurring in the liver in which glucuronic acid is conjugated with toxins.
- Glutamic Oxaloacetate Transaminase (GOT)** Catalyzes the transfer of an amino group from an amino acid (Glu) to a 2-keto-acid to generate a new amino acid and the residual 2-keto-acid of the donor amino acid.
- Glutamic Pyruvate Transaminase (GPT)** See Alanine Aminotransferase.
- Glutathione (GSH)** A tripeptide produced in the human liver and plays a key role in intermediary metabolism, immune response and health. It plays an important role in scavenging free radicals and protects cells against several toxic oxygen-derived chemical species.

- Glutathione Peroxidase (GPX)** The general name of an enzyme family with peroxidase activity whose main biological role is to protect the organism from oxidative damage.
- Glutathione S-Transferase (GST)** A major group of detoxification enzymes that participate in the detoxification of reactive electrophilic compounds by catalyzing their conjugation to glutathione.
- Glycaemic Index (GI)** Measures carbohydrates according to how quickly they are absorbed and raise the glucose level of the blood.
- Glycaemic Load (GL)** Is a ranking system for carbohydrate content in food portions based on their glycaemic index and the amount of available carbohydrate, i.e. $GI \times \text{available carbohydrate} \div 100$. Glycaemic load combines both the quality and quantity of carbohydrate in one 'number'. It is the best way to predict blood glucose values of different types and amounts of food.
- Glycation or Glycosylation** A chemical reaction in which glycosyl groups are added to a protein to produce a glycoprotein.
- Glycogenolysis** Is the catabolism of glycogen by removal of a glucose monomer through cleavage with inorganic phosphate to produce glucose-1-phosphate.
- Glycometabolism** Metabolism (oxidation) of glucose to produce energy.
- Glycosuria** Or glucosuria is an abnormal condition of osmotic diuresis due to excretion of glucose by the kidneys into the urine.
- Glycosylases** A family of enzymes involved in base excision repair.
- Goitre** An enlargement of the thyroid gland leading to swelling of the neck or larynx.
- Goitrogen** Substance that suppresses the function of the thyroid gland by interfering with iodine uptake, causing enlargement of the thyroid, i.e. goitre.
- Goitrogenic** *Adj.* causing goitre.
- Gonadotroph** A basophilic cell of the anterior pituitary specialized to secrete follicle-stimulating hormone or luteinizing hormone.
- Gonadotropins** Protein hormones secreted by gonadotrope cells of the pituitary gland of vertebrates.
- Gonorrhoea** A common sexually transmitted bacterial infection caused by the bacterium *Neisseria gonorrhoeae*.
- Gout** A disorder caused by a buildup of a waste product, uric acid, in the bloodstream. Excess uric acid settles in joints causing inflammation, pain and swelling.
- G-Protein-Coupled Receptors (GPCRs)** Constitute the largest family of cell surface molecules involved in signal transmission. These receptors play key physiological roles and their dysfunction results in several diseases.
- Granulation** The condition or appearance of being granulated (becoming grain-like).
- Gravel** Sand-like concretions of uric acid, calcium oxalate and mineral salts formed in the passages of the biliary and urinary tracts.
- Gripe Water** Is a home remedy for babies with colic, gas, teething pain or other stomach ailments. Its ingredients vary and may include alcohol, bicarbonate, ginger, dill, fennel and chamomile.
- Grippe** An epidemic catarrh; older term for influenza.
- GSH** See Glutathione.
- GSH-PxGlutathione peroxidase.** General name of an enzyme family with peroxidase activity whose main biological role is to protect the organism from oxidative damage.
- GSSG** Glutathione disulphides are biologically important intracellular thiols, and alterations in the GSH/GSSG ratio are often used to assess exposure of cells to oxidative stress.
- GSTM** Glutathione S-transferase M1. A major group of detoxification enzymes.
- GSTM 2** Glutathione S-transferase M2. A major group of detoxification enzymes.
- G2-M Cell Cycle** The phase where the cell prepares for mitosis and where chromatids and daughter cells separate.
- Guillain-Barre Syndrome** Is a serious disorder that occurs when the body's defense (immune) system mistakenly attacks part of the nervous system, leading to nerve inflammation, muscle weakness and other symptoms.
- Gynecopathy** Any or various diseases specific to women.

- Gynoid Adiposity** Fat distribution mainly to the hips and thighs, pear shaped.
- Haemagogic** Promoting a flow of blood.
- Haematemesis, Hematemesis** Is the vomiting of blood.
- Haematinic** Improving the quality of the blood, its haemoglobin level and the number of erythrocytes.
- Haematochezia** Passage of stools containing blood.
- Haematochyluria, Hematochyluria** The discharge of blood and chyle (emulsified fat) in the urine; see also Chyluria.
- Haematoma, Hematoma** A localized accumulation of blood in a tissue or space composed of clotted blood.
- Haematometra, Hematometra** A medical condition involving bleeding of or near the uterus.
- Haematopoiesis, Hematopoiesis** Formation of blood cellular components from the haematopoietic stem cells.
- Haematopoietic** *Adj.* relating to the formation and development of blood cells.
- Haematuria, Hematuria** Is the presence of blood in the urine. Haematuria is a sign that something is causing abnormal bleeding in a person's genitourinary tract.
- Haeme Oxygenase** HO-1, encoded by Hmox1, is an inducible protein activated in systemic inflammatory conditions by oxidant stress; an enzyme that catalyzes degradation of heme.
- Haemochromatosis** Iron overload in the body with a hereditary or primary cause.
- Haemodialysis, Hemodialysis** A method for removing waste products such as potassium and urea, as well as free water from the blood when the kidneys are in renal failure.
- Haemolysis** Lysis of red blood cells and the release of haemoglobin into the surrounding fluid (plasma). *Adj.* haemolytic.
- Haemoptysis, Hemoptysis** Is the coughing up of blood from the respiratory tract. The blood can come from the nose, mouth, throat and the airway passages leading to the lungs.
- Haemorrhage, Hemorrhage** Bleeding, discharge of blood from blood vessels.
- Haemorrhoids, Hemorrhoids** A painful condition in which the veins around the anus or lower rectum are enlarged, swollen and inflamed. Also called piles.
- Haemostasis, Hemostasis** A complex process which causes the bleeding process to stop.
- Haemostatic, Hemostatic** Something that stops bleeding.
- Halitosis** Bad breath, a common condition caused by sulphur-producing bacteria that live within the surface of the tongue and in the throat.
- Hallucinogen** Drug that produces hallucinogen.
- Hallucinogenic** Inducing hallucinations.
- Hallux Abducto Valgus** Commonly called bunion is an abnormal bending of the big toe towards the other toes of the foot.
- Haplotype** A set of alleles of closely linked loci on a chromosome that tend to be inherited together.
- Hapten** A small molecule that can elicit an immune response only when attached to a large carrier such as a protein.
- HATs** Histone acetyl transferases. Enzymes that regulate the acetylation of histones and transcription factors, playing a major role in the growth and differentiation of cells.
- HbA1c** Glycosylated haemoglobin.
- HBeAg** Hepatitis B e antigen.
- HBsAg** Hepatitis B s antigen.
- Heartburn** Burning sensation in the stomach and oesophagus caused by excessive acidity of the stomach fluids.
- Heat Rash** Any condition aggravated by heat or hot weather such as intertrigo.
- Heat-Shock Chaperones (HSC)** Ubiquitous molecules involved in the modulation of protein conformational and complexation states, associated with heat stress or other cellular stress response.
- Heat-Shock Proteins (HSP)** A group of functionally related proteins, the expression of which is increased when the cells are exposed to elevated temperatures or other cellular stresses.
- Helminthiasis** A disease in which a part of the body is infested with worms such as pinworm, roundworm or tapeworm.
- Hemagglutination** A specific form of agglutination that involves red blood cells.
- Haemagglutination-Inhibition Test** Measures of the ability of soluble antigen to inhibit the

- agglutination of antigen-coated red blood cells by antibodies.
- Hemagglutinin** Refers to a substance that causes red blood cells to agglutinate.
- Haemangioma** Blood vessel.
- Haematocrit** Is a blood test that measures the percentage of the volume of whole blood that is made up of red blood cells.
- Haematopoietic** Pertaining to the formation of blood or blood cells.
- Haematopoietic Stem Cell** Is a cell isolated from the blood or bone marrow that can renew itself and can differentiate to a variety of specialized cells.
- Heme Oxygenase-1 (HO-1)** An enzyme that catalyzes the degradation of heme; an inducible stress protein, confers cytoprotection against oxidative stress in vitro and in vivo.
- Haemoglobinopathies** Genetic defects that produce abnormal haemoglobins and anaemia.
- Haemolytic Anaemia** Anaemia due to haemolysis; the breakdown of red blood cells in the blood vessels or elsewhere in the body.
- Haemorheology** Study of blood flow and its elements in the circulatory system. *Adj.* haemorheological.
- Haemorrhagic Colitis** An acute gastroenteritis characterized by overtly bloody diarrhoea that is caused by *Escherichia coli* infection.
- Haemolytic-Uremic Syndrome** Is a disease characterized by haemolytic anaemia, acute renal failure (uraemia) and a low platelet count.
- Hepa-1c1c7** A type of hepatoma cells.
- Hepatalgia** Pain or discomfort in the liver area.
- Hepatomegaly** Condition of enlarged liver.
- Hepatectomy** The surgical removal of part or all of the liver.
- Hepatic** Relating to the liver.
- Hepatic Cirrhosis** Affecting the liver and characterized by hepatic fibrosis and regenerative nodules.
- Hepatic Fibrosis** Is overly profuse wound healing in which excessive connective tissue builds up in the liver.
- Hepatitis** Inflammation of the liver.
- Hepatitis A** Formerly known as infectious hepatitis, is an acute infectious disease of the liver caused by the hepatovirus hepatitis A virus.
- Hepatocarcinogenesis** Represents a linear and progressive cancerous process in the liver in which successively more aberrant monoclonal populations of hepatocytes evolve.
- Hepatocellular Carcinoma (HCC)** Also called malignant hepatoma, is a primary malignancy (cancer) of the liver.
- Hepatocytolysis** Cytotoxicity (dissolution) of liver cells.
- Hepatoma** Cancer of the liver.
- Hepatopathy** A disease or disorder of the liver.
- Hepatoprotective** Liver protector, a substance that helps protect the liver from damage by toxins, chemicals or other disease processes.
- Hepatoregenerative** A compound that promotes hepatocellular regeneration and repairs and restores liver function to optimum performance.
- Hepatotonic** Liver tonic, a substance that is tonic to the liver—usually employed to normalize liver enzymes and function.
- Hernia** Occurs when part of an internal organ bulges through a weak area of muscle.
- HER-2** Human epidermal growth factor receptor 2. A protein giving higher aggressiveness in breast cancer, also known as ErbB-2, ERBB2.
- Herpes** A chronic inflammation of the skin or mucous membrane characterized by the development of vesicles on an inflammatory base.
- Herpes Circinatus** Dermatitis herpetiformis (resembling herpes).
- Herpes Simplex Virus 1 and 2 (HSV-1 and HSV-2)** Are two species of the herpes virus family which cause a variety of illnesses/infections in humans such cold sores, chickenpox or varicella, shingles or herpes zoster (VZV), cytomegalovirus (CMV) and various cancers and can cause brain inflammation (encephalitis). HSV-1 is commonly associated with herpes outbreaks of the face known as cold sores or fever blisters, whereas HSV-2 is more often associated with genital herpes. They are also called human herpes virus 1 and 2 (HHV-1 and HHV-2) and are neurotropic and neuroinvasive viruses; they enter and hide in the human nervous system, accounting for their durability in the human body.
- Herpes Zoster** Or simply zoster, commonly known as shingles and also known as zona, is

a viral disease characterized by a painful skin rash with blisters.

Herpes Zoster Ophthalmicus (HZO) Is a viral ocular disease characterized by a painful skin rash in one or more dermatome distributions of the fifth cranial nerve, shared by the eye and orbit.

Heterophobia Term used to describe irrational fear of, aversion to or discrimination against heterosexuals.

HDL-C (HDL Cholesterol) High-density lipoprotein-cholesterol, also called 'good cholesterol'. See also High-Density Lipoprotein.

Hiatus Hernia Occurs when the upper part of the stomach pushes its way through a tear in the diaphragm.

High-Density Lipoprotein (HDL) Is one of the five major groups of lipoproteins which enable cholesterol and triglycerides to be transported within the water-based blood stream. HDL can remove cholesterol from atheroma within arteries and transport it back to the liver for excretion or reutilization—which is the main reason why HDL-bound cholesterol is sometimes called 'good cholesterol', or HDL-C. A high level of HDL-C seems to protect against cardiovascular diseases. Cf. LDL.

HGPRT, HPRT (Hypoxanthine-Guanine Phosphoribosyl Transferase) An enzyme that catalyzes the conversion of 5-phosphoribosyl-1-pyrophosphate and hypoxanthine, guanine or 6-mercaptopurine to the corresponding 5'-mononucleotides and pyrophosphate. The enzyme is important in purine biosynthesis as well as central nervous system functions.

Hippocampus A ridge in the floor of each lateral ventricle of the brain that consists mainly of grey matter.

Hippocampal Pertaining to the hippocampus.

Hirsutism A condition where women have excess facial and body hair that is dark and coarse.

Histaminergic Liberated or activated by histamine, relating to the effects of histamine at histamine receptors of target tissues.

Histaminergic Receptors Are types of G-protein-coupled receptors with histamine as their endogenous ligand.

Histone Acetyltransferases (HAT) Are enzymes that acetylate conserved lysine amino acids on histone proteins by transferring an acetyl group from acetyl-CoA to form *N*-acetyl lysine. HATs act as transcriptional coactivators.

Histone Lysine Demethylases (KDMs) Enzymes that play a key role in the amplification of hypoxia-inducible-factor signalling and expression of pro-angiogenic genes in cancer and neurological disorders.

HIV See Human Immunodeficiency Virus.

Hives Urticaria, is a skin rash characterized by circular wheals of reddened and itching skin.

HLA Human leukocyte antigen system. Name of the major histocompatibility complex (MHC) in humans.

HLA-DQB1 Human leukocyte antigen beta chain.

HLA-DR A major histocompatibility complex (MHC) class II cell surface receptor encoded by the human leukocyte antigen complex on chromosome 6 region 6p21.31.

HMG-CoA 3-Hydroxy-3-methylglutaryl-CoA reductase or (HMGCR) is the rate-controlling enzyme (EC 1.1.1.88) of the mevalonate pathway.

HMG-CoA 3-Hydroxy-3-methylglutaryl-coenzyme A. An intermediate in the mevalonate pathway.

Hodgkin's Disease Disease characterized by enlargement of the lymph glands, spleen and anaemia.

Homeodomain Transcription Factor A protein domain encoded by a homeobox. Homeobox genes encode transcription factors which typically switch on cascades of other genes.

Homeostasis The maintenance of a constant internal environment of a cell or an organism, despite fluctuations in the external.

Homeotherapy Treatment or prevention of disease with a substance similar but not identical to the causative agent of the disease.

Homocysteine An amino acid in the blood.

Homograft See Allograft.

Hormesis A term used by toxicologists to refer to a biphasic dose-response to an environmental agent characterized by a low-dose stimulation or beneficial effect and a high-dose inhibitory or toxic effect.

- Hormonal (Female)** Substance that has a hormonelike effect similar to that of oestrogen and/or a substance used to normalize female hormone levels.
- Hormonal (Male)** Substance that has a hormonelike effect similar to that of testosterone and/or a substance used to normalize male hormone levels.
- HRT** Hormone replacement therapy. The administration of the female hormones, oestrogen and progesterone and sometimes testosterone.
- HSP27** Is an ATP-independent, 27 kDa heat-shock protein chaperone that confers protection against apoptosis.
- HSP90** A 90 kDa heat-shock protein chaperone that has the ability to regulate a specific subset of cellular signalling proteins that have been implicated in disease processes.
- hTERT-(TERT)** Telomerase reverse transcriptase is a catalytic subunit of the enzyme telomerase in humans. It exerts a novel protective function by binding to mitochondrial DNA, increasing respiratory chain activity and protecting against oxidative stress-induced damage.
- HT29 Cells** Are human intestinal epithelial cells which produce the secretory component of immunoglobulin A (IgA) and carcinoembryonic antigen (CEA).
- Human Cytomegalovirus (HCMV)** A DNA herpes virus which is the leading cause of congenital viral infection and mental retardation.
- Human Factor X** A coagulation factor also known by the eponym Stuart-Prower factor or as thrombokinase; it is an enzyme involved in blood coagulation. It synthesized in the liver and requires vitamin K for its synthesis.
- Human Immunodeficiency Virus (HIV)** A retrovirus that can lead to acquired immunodeficiency syndrome (AIDS), a condition in humans in which the immune system begins to fail, leading to life-threatening opportunistic infections.
- Humoral Immune Response (HIR)** Is the aspect of immunity that is mediated by secreted antibodies (as opposed to cell-mediated immunity, which involves T lymphocytes) produced in the cells of the B lymphocyte lineage (B cell).
- HUVEC** Human umbilical vein endothelial cells.
- Hyaluronidase** Enzymes that catalyze the hydrolysis of certain complex carbohydrates like hyaluronic acid and chondroitin sulphates.
- Hydatidiform** A rare mass or growth that forms inside the uterus at the beginning of a pregnancy.
- Hydrocele** Abnormal accumulation of fluid inside the scrotum.
- Hydrocholeretic** An agent that stimulates an increased output of bile of low specific gravity.
- Hydrogogue** A purgative that causes an abundant watery discharge from the bowel.
- Hydronephrosis** Is distension and dilation of the renal pelvis and calyces, usually caused by obstruction of the free flow of urine from the kidney.
- Hydrophobia** A viral neuroinvasive disease that causes acute encephalitis (inflammation of the brain) in warm-blooded animals. Also called rabies.
- Hydropsy** See Dropsy.
- Hydrothorax** Accumulation of serous fluid in the pleural cavity.
- Hyperaemia** The increase of blood flow to different tissues in the body.
- Hyperalgesia** An increased sensitivity to pain (enhanced pricking pain), which may be caused by damage to nociceptors or peripheral nerves.
- Hyperammonemia, Hyperammonaemia** A metabolic disturbance characterized by an excess of ammonia in the blood.
- Hypercalciuria** *Idiopathic*, presence of excess calcium in the urine without obvious cause.
- Hypercholesterolaemia** High levels of cholesterol in the blood that increase a person's risk for cardiovascular disease leading to stroke or heart attack.
- Hyperaemia** Is the increased blood flow that occurs when tissue is active.
- Hyperemesis** Severe and persistent nausea and vomiting (morning sickness) during pregnancy.
- Hyperfibrinogenaemia** Excessive fibrinogen in the blood.
- Hyperglycaemia hyperglycaemic** High blood sugar; is a condition in which an excessive amount of glucose circulates in the blood plasma.

Hyperglycaemic A substance that raises blood sugar levels.

Hyperhomocysteinaemia Is a medical condition characterized by an abnormally large level of homocysteine in the blood.

Hyperinsulinaemia A condition in which there are excess levels of circulating insulin in the blood, also known as prediabetes.

Hyperkalaemia Is an elevated blood level of the electrolyte potassium.

Hyperkeratosis Abnormal thickening of the outer layer of the skin. *Adj.* hyperkeratotic.

Hyperkinesis Enhanced itch to pricking.

Hyperleptinaemia Increased serum leptin level.

Hyperlipoproteinaemia A metabolic disorder characterized by abnormally elevated concentrations of lipid/lipoprotein in the plasma, also known as hyperlipidaemia and hyperlipaemia.

Hypermenorrhoea Abnormally heavy or prolonged menstruation.

Hypermethylation An increase in the inherited methylation of cytosine and adenosine residues in DNA.

Hyperphagia Or polyphagia. Abnormally large ingestion of food beyond that needed for basic energy requirements.

Hyperpiesia Persistent and pathological high blood pressure for which no specific cause can be found.

Hyperplasia Increased cell production in a normal tissue or organ.

Hyperprebeta-Lipoproteinaemia Increased concentrations of pre-beta-lipoproteins in the blood.

Hyperpropulsion Using water pressure as a force to move objects; used to dislodge calculi in the urethra.

Hyperpyrexia Is an abnormally high fever.

Hypertension Commonly referred to as 'high blood pressure' or HTN, is a medical condition in which the arterial blood pressure is chronically elevated.

Hypertensive Characterized or caused by increased tension or pressure as abnormally high blood pressure.

Hypertonia Abnormal increase in muscle tension and a reduced ability of the muscle to stretch.

Hypertriglyceridaemia or Hypertriglycemia A disorder that causes high triglycerides in the blood.

Hypertrophy Enlargement or overgrowth of an organ.

Hyperuricemia Is a condition characterized by abnormally high level of uric acid in the blood.

Hypoadiponectinaemia The state of having too low level of adiponectin, a major metabolic endocrine, responsible for regulating things like glucose uptake and lipolysis (the breakdown of fat deposits); low adiponectin is a risk factor for both type II diabetes and metabolic syndrome.

Hypoalbuminaemia A medical condition where levels of albumin in blood serum are abnormally low.

Hypocalcemic Tetany A disease caused by an abnormally low level of calcium in the blood and characterized by hyperexcitability of the neuromuscular system and results in carpopedal spasms.

Hypochlorhydria Refer to states where the production of gastric acid in the stomach is absent or low.

Hypocholesterolemic Cholesterol reducer, a substance that lowers blood cholesterol levels.

Hypocitraturia Low amount of citrate in the urine, an important risk factor for kidney stone formation.

Hypocorticism See Addison's Disease.

Hypocortisolism See Addison's Disease.

Hypoesthesia (or Hypaesthesia) Refers to a reduced sense of touch or sensation or a partial loss of sensitivity to sensory stimuli.

Hypoglycemic An agent that lowers the concentration of glucose (sugar) in the blood.

Hypoperfusion Decreased blood flow through an organ, characterized by an imbalance of oxygen demand and oxygen delivery to tissues.

Hypophagic Under-eating.

Hypospadias An abnormal birth defect in males in which the urethra opens on the under surface of the penis.

Hypotensive Characterized by or causing diminished tension or pressure, as abnormally low blood pressure.

- Hypothermia** A condition in which an organism's temperature drops below that required for normal metabolism and body functions.
- Hypothermic** Relating to hypothermia, with subnormal body temperature.
- Hypoxaemia** Is the reduction of oxygen specifically in the blood.
- Hypoxia** A shortage of oxygen in the body. *Adj.* hypoxic.
- Hypoxia-Inducible Factors (HIFs)** Transcription factors that respond to changes in available oxygen in the cellular environment, specifically to deficiency in oxygen.
- ICAM-1 (Intercellular Adhesion Molecule 1)** Also known as CD54 (cluster of differentiation 54), is a protein that in humans is encoded by the ICAM1 gene.
- IC₅₀** The median maximal inhibitory concentration; a measure of the effectiveness of a compound in inhibiting biological or biochemical function.
- I.C.V. (Intra-cerebroventricular)** Injection of chemical into the right lateral ventricle of the brain.
- Ichthyotoxic** A substance which is poisonous to fish.
- Icterus** Jaundice, yellowish pigmentation of the skin.
- Icteric Hepatitis** An infectious syndrome of hepatitis characterized by jaundice, nausea, fever, right-upper quadrant pain, enlarged liver and transaminitis (increase in alanine aminotransferase (ALT) and/or aspartate aminotransferase (AST)).
- Icterus Neonatorum** Jaundice in newborn infants.
- Idiopathic** Of no apparent physical cause.
- Idiopathic Sudden Sensorineural Hearing Loss (ISSHL)** Is sudden hearing loss where clinical assessment fails to reveal a cause.
- Ig** Gastric intubation, insertion of Levin tube through the nasal passage to the stomach.
- IgE** Immunoglobulin E. A class of antibody that plays a role in allergy.
- IGFs/Insulin-like** growth factors, polypeptides with high sequence similarity to insulin.
- IgG** Immunoglobulin G. The most abundant immunoglobulin (antibody) and is one of the major activators of the complement pathway.
- IgM** Immunoglobulin M. Primary antibody against A and B antigens on red blood cells.
- IKAP** Is a scaffold protein of the Ikaros/Beta kinase complex and a regulator for kinases involved in pro-inflammatory cytokine signalling.
- IKappa B** Or IκB-beta, a protein of the NF-Kappa-B inhibitor family.
- Ileus** A temporary disruption of intestinal peristalsis due to nonmechanical causes.
- Immune Modulator** A substance that affects or modulates the functioning of the immune system.
- Immunodeficiency** A state in which the immune system's ability to fight infectious disease is compromised or entirely absent.
- Immunogenicity** The property enabling a substance to provoke an immune response. *Adj.* immunogenic.
- Immunoglobulin Class Switching Ig Class Switching** A biological mechanism that changes a B cell's production of antibody from one class to another.
- Immunomodulatory** Capable of modifying or regulating one or more immune functions.
- Immunoreactive** Reacting to particular antigens or haptens.
- Immunostimulant** Agent that stimulates an immune response.
- Immunosuppression** Involves a process that reduces the activation or efficacy of the immune system.
- Immunotoxin** A man-made protein that consists of a targeting portion linked to a toxin.
- Impaired Glucose Tolerance (IGT)** A prediabetic state of dysglycemia associated with insulin resistance and increased risk of cardiovascular pathology and also a risk factor for mortality.
- Impetigo** A contagious, bacterial skin infection characterized by blisters that may itch, caused by a *Streptococcus* bacterium or *Staphylococcus aureus* and mostly seen in children.
- Impotence** A sexual dysfunction characterized by the inability to develop or maintain an erection of the penis.
- Incontinence (Faecal)** The inability to control bowel's movement.

Incontinence (Urine) The inability to control urine excretion.

Incretin A group of gastrointestinal hormones that cause an increase in the amount of insulin released from the beta cells of the islets of Langerhans after a meal; members include GIP and GLP-1.

Index of Structural Atypia (ISA) Index of structural abnormality.

Induration Hardened, as a soft tissue that becomes extremely firm, sclerosis.

Infarct An area of living tissue that undergoes necrosis as a result of obstruction of local blood supply.

Infarction Is the process of tissue death (necrosis) caused by blockage of the tissue's blood supply.

Inflammation A protective response of the body to infection, irritation or other injury, aimed at destroying or isolating the injuries and characterized by redness, pain, warmth and swelling.

Influenza A viral infection that affects mainly the nose, throat, bronchi and, occasionally, lungs.

Infusion A liquid extract obtained by steeping something (e.g. herbs) that are more volatile or dissolve readily in water, to release their active ingredients without boiling.

Inguinal Hernia An hernia into the inguinal canal of the groin.

Inhalant A medicinal substance that is administered as a vapour into the upper respiratory passages.

iNOS, Inducible Nitric Oxide Synthases Through its product, nitric oxide (NO), may contribute to the induction of germ cell apoptosis. It plays a crucial role in early sepsis-related microcirculatory dysfunction.

Inotropic Affecting the force of muscle contraction.

Insecticide An agent that destroys insects. *Adj.* insecticidal.

Insomnia A sleeping disorder characterized by the inability to fall asleep and/or the inability to remain asleep for a reasonable amount of time.

Insulin A peptide hormone composed of 51 amino acids produced in the islets of Langerhans in the pancreas causes cells in the liver, muscle and fat tissue to take up glucose

from the blood, storing it as glycogen in the liver and muscle. Insulin deficiency is often the cause of diabetes, and exogenous insulin is used to control diabetes.

Insulin Homeostasis Blood sugar regulation.

Insulin-like Growth Factors (IGFs) Polypeptides with high sequence similarity to insulin. They are part of a complex system that cells employ to communicate with their physiologic environment.

Insulin-Mimetic To act like insulin.

Insulin Resistance A condition where the natural hormone insulin becomes less effective at reducing blood sugars.

Insulinogenic Associated with or stimulating the production of insulin.

Insulinotropic Stimulating or affecting the production and activity of insulin.

Integrase An enzyme produced by a retrovirus (such as HIV) that enables its genetic material to be integrated into the DNA of the infected cell.

Interferons (IFNs) Are natural cell-signalling glycoproteins known as cytokines produced by the cells of the immune system of most vertebrates in response to challenges such as viruses, parasites and tumour cells.

Interleukins A group of naturally occurring proteins and is a subset of a larger group of cellular messenger molecules called cytokines, which are modulators of cellular behaviour.

Interleukin-1 (IL-1) A cytokine that could induce fever, control lymphocytes, increase the number of bone marrow cells and cause degeneration of bone joints. Also called endogenous pyrogen, lymphocyte-activating factor, haemopoietin-1 and mononuclear cell factor, amongst others, that IL-1 is composed of two distinct proteins, now called IL-1 α and IL-1 β .

Interleukin 1 Beta (IL-1 β) A cytokine protein produced by activated macrophages. Cytokine is an important mediator of the inflammatory response and is involved in a variety of cellular activities, including cell proliferation, differentiation and apoptosis.

Interleukin 2 (IL-2) A type of cytokine immune system signalling molecule that is instrumental in the body's natural response to microbial infection.

Interleukin-2 Receptor (IL-2R) A heterotrimeric protein expressed on the surface of certain immune cells, such as lymphocytes, that binds and responds to a cytokine called IL-2.

Interleukin-6 (IL-6) An interleukin that acts as both a pro-inflammatory and antiinflammatory cytokine.

Interleukin 8 (I-8) A cytokine produced by macrophages and other cell types such as epithelial cells and is one of the major mediators of the inflammatory response.

Intermediate-Density Lipoproteins (IDL) Is one of the five major groups of lipoproteins (chylomicrons, VLDL, IDL, LDL and HDL) that enable fats and cholesterol to move within the water-based solution of the bloodstream. IDL is further degraded to form LDL particles and, like LDL, can also promote the growth of atheroma and increase cardiovascular diseases.

Intermittent Claudication An aching, crampy, tired and sometimes burning pain in the legs that comes and goes, caused by peripheral vascular disease. It usually occurs when walking and disappears after rest.

Interoceptive Relating to stimuli arising from within the body.

Interstitium The space between cells in a tissue.

Interstitial Pertaining to the interstitium.

Intertrigo An inflammation (rash) caused by microbial infection in skin folds.

Intima Innermost layer of an artery or vein.

Intoxicant Substance that produce drunkenness or intoxication.

Intracavernosal Within the corpus cavernosum, columns of erectile tissues forming the body of the penis.

Intraperitoneal (i.p.) The term used when a chemical is contained within or administered through the peritoneum (the thin, transparent membrane that lines the walls of the abdomen).

Intrathecal (i.t.) Through the theca of the spinal cord into the subarachnoid space.

Intromission The act of putting one thing into another.

Intubation Refers to the placement of a tube into an external or internal orifice of the body.

Iodine (I) Is an essential chemical element that is important for hormone development in the

human body. Lack of iodine can lead to an enlarged thyroid gland (goitre) or other iodine deficiency disorders including mental retardation and stunted growth in babies and children. Iodine is found in dairy products, seafood, kelp, seaweeds, eggs, some vegetables and iodized salt.

IP See Intraperitoneal.

IP3R3 Inositol 1,4,5-triphosphate receptor type 3, is an intracellular calcium release channel that mediates calcium release from the endoplasmic reticulum.

Iron (Fe) Is essential to most life forms and to normal human physiology. In humans, iron is an essential component of proteins involved in oxygen transport and for haemoglobin. It is also essential for the regulation of cell growth and differentiation. A deficiency of iron limits oxygen delivery to cells, resulting in fatigue, poor work performance and decreased immunity. Conversely, excess amounts of iron can result in toxicity and even death. Dietary sources include certain cereals, dark green leafy vegetables, dried fruit, legumes, seafood, poultry, and meat.

Ischemia An insufficient supply of blood to an organ, usually due to a blocked artery.

Ischuria Retention or suppression of urine.

Isoflavones A subgroup of flavonoids in which the basic structure is a 3-phenyl chromane skeleton. They act as phytoestrogens in mammals. See Flavonoids.

Isomers Substances that are composed of the same elements in the same proportions and hence have the same molecular formula but differ in properties because of differences in the arrangement of atoms.

Isoprostanes Unique prostaglandin-like compounds generated in vivo from the free radical-catalyzed peroxidation of essential fatty acids.

Jamu Traditional Indonesian herbal medicine.

Janus Kinase (JAK)–Signal Transducer and Activator of Transcription (STAT) Signalling Are essential molecules in cytokine signal transduction pathways involved in cancer development and progression.

- Jaundice** Refers to the yellow colour of the skin and whites of the eyes caused by excess bilirubin in the blood.
- JNK** Jun N-terminal kinase, also known as stress-activated protein kinase (SAPK), belongs to the family of MAP kinases.
- Jurkat Cells** A line of T lymphocyte cells that are used to study acute T cell leukaemia.
- KB Cell** A cell line derived from a human carcinoma of the nasopharynx, used as an assay for antineoplastic (antitumour) agents.
- Kaliuresis** The presence of excess potassium in the urine.
- Kallikreins** Peptidases (enzymes that cleave peptide bonds in proteins), a subgroup of the serine protease family; they liberate kinins from kininogens. Kallikreins are targets of active investigation by drug researchers as possible biomarkers for cancer.
- Kaposi Sarcoma** A cancerous tumour of the connective tissues caused by the human herpes virus-8 and is often associated with AIDS.
- Kaposi Sarcoma Herpes Virus (KSHV)** Also known as human herpes virus-8, is a gamma 2 herpes virus or rhadinovirus. It plays an important role in the pathogenesis of Kaposi sarcoma (KS), multicentric Castleman's disease (MCD) of the plasma cell type and primary effusion lymphoma and occurs in HIV patients.
- Karyolysis** Dissolution and disintegration of the nucleus when a cell dies.
- Karyorrhexis** Destructive fragmentation of the nucleus of a dying cell whereby its chromatin disintegrates into formless granules.
- Keloids** Benign dermal tumours characterized by fibroblastic proliferation and excessive accumulation of collagen.
- Keratin** A sulphur-containing protein which is a major component in skin, hair, nails, hooves, horns and teeth.
- Keratinocyte** Is the major constituent of the epidermis, constituting 95 % of the cells found there.
- Keratinophilic** Having an affinity for keratin.
- Keratitis** Inflammation of the cornea.
- Keratolysis** Softening and separation of the horny layer of the epidermis.
- Keratolytic** Pertaining to keratolysis.
- Keratomalacia** An eye disorder that leads to a dry cornea.
- Kidney Stones** Calculi are hardened mineral deposits that form in the kidney.
- Kinin** Is any of various structurally related polypeptides, such as bradykinin, that act locally to induce vasodilation and contraction of smooth muscle.
- Kininogen** Either of two plasma α 2-globulins that are kinin precursors.
- Ki-67** Human protein associated with cell proliferation.
- Knockout** Gene knockout is a genetic technique in which an organism is engineered to carry genes that have been made inoperative.
- Kunitz Protease Inhibitors** A type of protein contained in legume seeds which functions as a protease inhibitor.
- Kupffer Cells** Are resident macrophages of the liver and play an important role in its normal physiology and homeostasis as well as participating in the acute and chronic responses of the liver to toxic compounds.
- L-DOPA** L-3,4-dihydroxyphenylalanine, is an amino acid that is formed in the liver and converted into dopamine in the brain.
- Labour** Process of childbirth involving muscular contractions.
- Lacrimation** Secretion and discharge of tears.
- Lactagogue** An agent that increases or stimulates milk flow or production. Also called a galactagogue.
- Lactate Dehydrogenase (LDH)** Enzyme that catalyzes the conversion of lactate to pyruvate.
- Lactation** Secretion and production of milk.
- Lactic Acidosis** Is a condition caused by the buildup of lactic acid in the body. It leads to acidification of the blood (acidosis) and is considered a distinct form of metabolic acidosis.
- LAK Cell** A lymphokine-activated killer cell, i.e. a white blood cell that has been stimulated to kill tumour cells.
- Laminin** A glycoprotein component of connective tissue basement membrane that promotes cell adhesion.
- Laparotomy** A surgical procedure involving an incision through the abdominal wall to gain

- access into the abdominal cavity. *Adj.* laparotomized.
- Larvacidal** An agent which kills insect or parasite larva.
- Laryngitis** Is an inflammation of the larynx.
- Laxation** Bowel movement.
- Laxatives** Substances that are used to promote bowel movement.
- LC 50** Median lethal concentration; see LD 50.
- LD 50** Median lethal dose. The dose required to kill half the members of a tested population. Also called LC 50 (median lethal concentration).
- LDL** See Low-Density Lipoprotein.
- LDL Cholesterol** See Low-Density Lipoprotein.
- LDL Receptor (LDLR)** A low-density lipoprotein receptor gene.
- Lectins** Are sugar-binding proteins that are highly specific for their sugar moieties that agglutinate cells and/or precipitate glycoconjugates. They play a role in biological recognition phenomena involving cells and proteins.
- Leishmaniasis** A disease caused by protozoan parasites that belong to the genus *Leishmania* and is transmitted by the bite of certain species of sand fly.
- Lenitive** Palliative; easing pain or discomfort.
- Lenticular Opacity** Also known as or related to cataract.
- Leprosy** A chronic bacterial disease of the skin and nerves in the hands and feet and, in some cases, the lining of the nose. It is caused by the *Mycobacterium leprae*. Also called Hansen's disease.
- Leptin** Is a 16 kDa protein hormone with important effects in regulating body weight, metabolism and reproductive function.
- Lequesne Algofunctional Index** Is a widespread international instrument (ten questions survey) and recommended by the World Health Organization (WHO) for outcome measurement in hip and knee diseases such as osteoarthritis.
- Leukocyte** White blood corpuscles, colourless, without haemoglobin that help to combat infection.
- Leucoderma** A skin abnormality characterized by white spots, bands and patches on the skin; they can also be caused by fungus and tinea. Also see Vitiligo.
- Leucorrhoea** Commonly known as whites, refers to a whitish discharge from the female genitals
- Leukemia, Leukaemia** A cancer of the blood or bone marrow and is characterized by an abnormal proliferation (production by multiplication) of blood cells, usually white blood cells (leukocytes).
- Leukemogenic** Relating to leukaemia, causing leukaemia.
- Leukocytopenia** Abnormal decrease in the number of leukocytes (white blood cells) in the blood.
- Leukomyelopathy** Any diseases involving the white matter of the spinal cord.
- Leukopenia** A decrease in the number of circulating white blood cells.
- Leukoplakia** Condition characterized by white spots or patches on mucous membranes, especially of the mouth and vulva.
- Leukotriene** A group of hormones that cause the inflammatory symptoms of hay fever and asthma.
- Levarterenol** See Norepinephrine.
- LexA Repressor** Or repressor LexA is repressor enzyme that represses SOS response genes coding for DNA polymerases required for repairing DNA damage.
- Leydig Cells** Also called interstitial cells of Leydig, are found adjacent to the seminiferous tubules in the testicle. They produce testosterone in response to luteinizing hormone.
- Libido** Sexual urge.
- Lichen Planus** a chronic mucocutaneous disease that affects the skin, tongue and oral mucosa.
- Ligroin** A volatile, inflammable fraction of petroleum, obtained by distillation and used as a solvent.
- Limbic System** Complex set of brain structures, including the hypothalamus, amygdala, hippocampus, anterior thalamic nuclei, septum, limbic cortex and fornix that control various functions such as emotion, behaviour, motivation, memory and olfaction.

- Liniment** Liquid preparation rubbed on skin used to relieve muscular aches and pains.
- Linterized Starch** Starch that has undergone prolonged acid treatment.
- Lipodiatic** Having lipid and lipoprotein lowering property.
- Lipodystrophy** A medical condition characterized by abnormal or degenerative conditions of the body's adipose tissue.
- Lipogenesis** Is the process by which acetyl-CoA is converted to fats.
- Lipolysis** Is the breakdown of fat stored in fat cells in the body.
- Liposomes** Artificially prepared vesicles made of lipid bilayer.
- Lipotoxicity** Refers to tissues diseases that may occur when fatty acids spill over in excess of the oxidative needs of those tissues and enhances metabolic flux into harmful pathways of nonoxidative metabolism.
- Lipotropic** Refers to compounds that help catalyze the breakdown of fat during metabolism in the body, e.g. chlorine and lecithin.
- Lipoxygenase** A family of iron-containing enzymes that catalyze the dioxygenation of polyunsaturated fatty acids in lipids containing a cis,cis-1,4-pentadiene structure.
- Lithiasis** Formation of urinary calculi (stones) in the renal system (kidneys, ureters, urinary bladder, urethra) and can be of any one of several compositions.
- Lithogenic** Promoting the formation of calculi (stones).
- Lithontriptic** Removes stones from kidney and gall bladder.
- Liver X Receptors** Nuclear hormones that function as central transcriptional regulators for lipid homeostasis.
- Lotion** A liquid suspension or dispersion of chemicals for external application to the body.
- LoVo Cells** Colon cancer cells.
- Low-Density Lipoprotein (LDL)** Is a type of lipoprotein that transports cholesterol and triglycerides from the liver to peripheral tissues. High levels of LDL cholesterol can signal medical problems like cardiovascular disease, and it is sometimes called 'bad cholesterol'.
- LRP1** Low-density lipoprotein receptor-related protein-1, plays a role in intracellular signalling functions as well as in lipid metabolism.
- LTB4** A type of leukotriene, is a major metabolite in neutrophil polymorphonuclear leukocytes. It stimulates polymorphonuclear cell function (degranulation, formation of oxygen-centred free radicals, arachidonic acid release and metabolism). It induces skin inflammation.
- Luciferase** Is a generic name for enzymes commonly used in nature for bioluminescence.
- Lumbago** Is the term used to describe general lower back pain.
- Lung Abscess** Necrosis of the pulmonary tissue and formation of cavities containing necrotic debris or fluid caused by microbial infections.
- Lusitropic** An agent that affects diastolic relaxation.
- Lutein** A carotenoid, occurs naturally as yellow or orange pigment in some fruits and leafy vegetables. It is one of the two carotenoids contained within the retina of the eye. Within the central macula, zeaxanthin predominates, whereas in the peripheral retina, lutein predominates. Lutein is necessary for good vision and may also help prevent or slow down atherosclerosis, the thickening of arteries, which is a major risk for cardiovascular disease.
- Luteinising Hormone (LH)** A hormone produced by the anterior pituitary gland. In females, it triggers ovulation. In males, it stimulates the production of testosterone to aid sperm maturation.
- Luteolysis** Is the structural and functional degradation of the corpus luteum (CL) that occurs at the end of the luteal phase of both the oestrous and menstrual cycles in the absence of pregnancy. *Adj.* luteolytic
- Luteotropic** Stimulating the formation of the corpus luteum.
- Lymphadenitis** The inflammation or enlargement of a lymph node caused by microbial infection.
- Cervical Lymphadenitis** Inflammation of the lymph nodes in the neck, usually caused by an infection.

Lymphatitis Inflammation of lymph vessels and nodes.

Lymphadenopathy A term meaning ‘disease of the lymph nodes’—lymph node enlargement.

Lymphadenomegaly Is the enlargement of the lymph node/nodes.

Lymphoblastic Pertaining to the production of lymphocytes.

Lymphocyte A small white blood cell (leukocyte) that plays a large role in defending the body against disease. Lymphocytes are responsible for immune responses. There are two main types of lymphocytes: B cells and T cells. Lymphocytes secrete products (lymphokines) that modulate the functional activities of many other types of cells and are often present at sites of chronic inflammation.

Lymphocyte B Cells The B cells make antibodies that attack bacteria and toxins.

Lymphocyte T Cells T cells attack body cells themselves when they have been taken over by viruses or have become cancerous.

Lymphoma A type of cancer involving cells of the immune system called lymphocytes.

Lymphopenia Abnormally low number of lymphocytes in the blood.

Lysosomes Are small, spherical organelles containing digestive enzymes (acid hydrolases) and other proteases (cathepsins).

Maceration Softening or separating of parts by soaking in a liquid.

Macrophage A type of large leukocyte that travels in the blood but can leave the bloodstream and enter tissue; like other leukocytes it protects the body by digesting debris and foreign cells.

Macular Degeneration A disease that gradually destroys the macula, the central portion of the retina, reducing central vision.

Macules Small circumscribed changes in the colour of skin that are neither raised (elevated) nor depressed.

Maculopapular Describes a rash characterized by raised, spotted lesions.

Magnesium (Mg) Is the fourth most abundant mineral in the body and is essential to good health. It is important for normal muscle and nerve function, steady heart rhythm, immune system and strong bones. Magnesium also

helps regulate blood sugar levels, promotes normal blood pressure and is known to be involved in energy metabolism and protein synthesis and plays a role in preventing and managing disorders such as hypertension, cardiovascular disease and diabetes. Dietary sources include legumes (e.g. soya bean and by-products), nuts, whole unrefined grains, fruit (e.g. banana, apricots), okra and green leafy vegetables.

MAK Cell Macrophage-activated killer cell. Activated macrophage that is much more phagocytic than monocytes.

Malaise A feeling of weakness, lethargy or discomfort as of impending illness.

Malaria Is an infection of the blood by *Plasmodium* parasite that is carried from person to person by mosquitoes. There are four species of malaria parasites that infect man: *Plasmodium falciparum*, so-called malignant tertian fever, is the most serious disease; *Plasmodium vivax*, causing a relapsing form of the disease; *Plasmodium malariae*; and *Plasmodium ovale*.

Malassezia A fungal genus (previously known as *Pityrosporum*) classified as yeasts, naturally found on the skin surfaces of many animals including humans. It can cause hypopigmentation on the chest or back if it becomes an opportunistic infection.

Mammalian Target of Rapamycin (mTOR) Pathway that regulates mitochondrial oxygen consumption and oxidative capacity.

Mammogram An X-ray of the breast to detect tumours.

Mandibular Relating to the mandible, the human jaw bone.

Manganese Is an essential element for health. It is an important constituent of some enzymes and an activator of other enzymes in physiologic processes. Manganese superoxide dismutase (MnSOD) is the principal antioxidant enzyme in the mitochondria. Manganese-activated enzymes play important roles in the metabolism of carbohydrates, amino acids and cholesterol. Manganese is the preferred cofactor of enzymes called glycosyltransferases which are required for the synthesis of proteoglycans that

are needed for the formation of healthy cartilage and bone. Dietary source include whole grains, fruit, legumes (soybean and by-products), green leafy vegetables, beetroot and tea.

MAO Activity Monoamine oxidase activity.

MAPK (Mitogen-Activated Protein Kinase)

These kinases are strongly activated in cells subjected to osmotic stress, UV radiation, dysregulated K^+ currents, RNA-damaging agents and a multitude of other stresses, as well as inflammatory cytokines, endotoxin and withdrawal of a trophic factor. The stress-responsive MAPKs mediate a plethora of cellular responses to such stressful stimuli, including apoptosis and production of inflammatory and immunoregulatory cytokines in diverse cell systems.

Marasmus Is one of the three forms of serious protein-energy malnutrition.

Mastectomy Surgery to remove a breast.

Masticatory A substance chewed to increase salivation. Also called sialogue.

Mastitis A bacterial infection of the breast which usually occurs in breastfeeding mothers.

Matrix Metalloproteinases (MMP) A member of a group of enzymes that can break down proteins, such as collagen, that are normally found in the spaces between cells in tissues (i.e. extracellular matrix proteins). Matrix metalloproteinases are involved in wound healing, angiogenesis and tumour cell metastasis. See also Metalloproteinase.

MBC Minimum bacterial concentration. The lowest concentration of antibiotic required to kill an organism.

MCP-1 Monocyte chemotactic protein-1. Plays a role in the recruitment of monocytes to sites of infection and injury. It is a member of small inducible gene (SIG) family.

MDA Malondialdehyde is one of the most frequently used indicators of lipid peroxidation.

Measles An acute, highly communicable rash illness due to a virus transmitted by direct contact with infectious droplets or, less commonly, by airborne spread.

Mechanonociceptors Sensory neurons that are mechanically sensitive found in all of the paraspinal connective tissues including

ligament, joint capsule, annulus fibrosus of the intervertebral disc, muscle, tendon and skin. They respond to a noxious (damaging) mechanical load.

Medial Preoptic Area Is located at the rostral end of the hypothalamus; it is important for the regulation of male sexual behaviour.

Megaloblastic Anaemia An anaemia that results from inhibition of DNA synthesis in red blood cell production, often due to a deficiency of vitamin B12 or folate and is characterized by many large immature and dysfunctional red blood cells (megaloblasts) in the bone marrow.

Melaena (Melena) Refers to the black, 'tarry' faeces that are associated with gastrointestinal haemorrhage.

Melanogenesis Production of melanin by living cells.

Melanoma Malignant tumour of melanocytes which are found predominantly in skin but also in the bowel and the eye and appear as pigmented lesions.

Melatonin A hormone produced in the brain by the pineal gland; it is important in the regulation of the circadian rhythms of several biological functions.

Menarche The first menstrual cycle, or first menstrual bleeding, in female human beings.

Menorrhagia Heavy or prolonged menstruation; too-frequent menstrual periods.

Menopausal Refer to permanent cessation of menstruation.

Menses See Menstruation.

Menstruation The approximately monthly discharge of blood from the womb in women of childbearing age who are not pregnant. Also called menses. *Adj.* menstrual.

Mesangial Cells Are specialized cells around blood vessels in the kidneys, at the mesangium.

Mesothelioma Is an aggressive cancer affecting the membrane lining of the lungs and abdomen.

Metabolic Syndrome (MetS) Represents a combination of cardiometabolic risk factors, including visceral obesity, glucose intolerance or type 2 diabetes, elevated triglycerides, reduced HDL cholesterol and hypertension.

- Metabonome** Complete set of metabolically regulated elements in cells.
- Metabolomics** Is the scientific study of chemical processes involving metabolites.
- Metalloproteinase** Enzymes that break down proteins and requiring zinc or calcium atoms for proper function.
- Metallothionein (MT)** A family of cysteine-rich, low molecular weight (500–14,000 Da) proteins.
- Meta-analysis** A statistical procedure that combines the results of several studies that address a set of related research hypotheses.
- Metaphysis** Is the portion of a long bone between the epiphyses and the diaphysis of the femur.
- Metaphyseal** Pertaining to the metaphysis.
- Metaplasia** Transformation of one type of one mature differentiated cell type into another mature differentiated cell type.
- Metastasis** Is the movement or spreading of cancer cells from one organ or tissue to another.
- Metestrus** the quiescent period of sexual inactivity between oestrous cycles.
- Metropathy** Any disease of the uterus especially of the myometrium.
- Metroptosis** The slipping or falling out of place of an organ (as the uterus).
- Metrorrhagia** Uterine bleeding at irregular intervals, particularly between the expected menstrual periods.
- Mevinolin** A potent inhibitor of 3-hydroxy-3-methylglutaryl coenzyme A reductase (HMG-CoA reductase).
- MHC** Acronym for major histocompatibility complex, a large cluster of genes found on the short arm of chromosome 6 in most vertebrates that encodes MHC molecules. MHC molecules play an important role in the immune system and autoimmunity.
- MHC 11 Molecules** Class II MHC molecules belong to a group of molecules known as the immunoglobulin supergene family, which includes immunoglobulins, T cell receptors, CD4, CD8 and others.
- MIC** Minimum inhibitory concentration. Lowest concentration of an antimicrobial that will inhibit the visible growth of a microorganism.
- Micelle** A submicroscopic aggregation of molecules.
- Micellization** Formation process of micelles.
- Microangiopathy** Or microvascular disease, is an angiopathy affecting small blood vessels in the body.
- Microfilaria** A pre-larval parasitic worm of the family Onchocercidae, found in the vector and in the blood or tissue fluid of human host.
- Micronuclei** Small particles consisting of acentric fragments of chromosomes or entire chromosomes, which lag behind at anaphase of cell division.
- Microsomal PGE2 Synthase** Is the enzyme that catalyzes the final step in prostaglandin E2 (PGE2) biosynthesis.
- Microvasculature** The finer vessels of the body, as the arterioles, capillaries and venules.
- Micturition** Urination, act of urinating.
- Migraine** A neurological syndrome characterized by altered bodily perceptions, severe, painful headaches and nausea.
- Mimosine** Is an alkaloid, β -3-hydroxy-4 pyridone amino acid; it is a toxic nonprotein free amino acid and is an antinutrient.
- Mineral Apposition Rate** MAR, rate of addition of new layers of mineral on the trabecular surfaces of bones.
- Miscarriage** Spontaneous abortion.
- Mitochondrial Complex I** The largest enzyme in the mitochondrial respiratory oxidative phosphorylation system.
- Mitochondrial Permeability Transition (MPT)** Is an increase in the permeability of the mitochondrial membranes to molecules of less than 1,500 Da in molecular weight. MPT is one of the major causes of cell death in a variety of conditions.
- Mitogen** An agent that triggers mitosis and elicits all the signals necessary to induce cell proliferation.
- Mitogenic** Able to induce mitosis or transformation.
- Mitogenicity** Process of induction of mitosis.
- Mitomycin** A chemotherapy drug that is given as a treatment for several different types of

- cancer, including breast, stomach, oesophagus and bladder cancers.
- Mitosis** Cell division in which the nucleus divides into nuclei containing the same number of chromosomes.
- MMP** Matrix metalloproteinases, a group of peptidases involved in degradation of the extracellular matrix (ECM).
- Mnestic** Pertaining to memory.
- Molecular Docking** Is a key tool in structural molecular biology and computer-assisted drug design.
- Molluscidal** Destroying molluscs like snails.
- MOLT4 Cells** MOLT4 cells are lymphoblast-like in morphology and are used for studies of apoptosis, tumour cytotoxicity, tumorigenicity, as well as for antitumour testing.
- Molybdenum (Mo)** Is an essential element that forms part of several enzymes such as xanthine oxidase involved in the oxidation of xanthine to uric acid and use of iron. Molybdenum concentrations also affect protein synthesis, metabolism and growth. Dietary sources include meat, green beans, eggs, sunflower seeds, wheat flour, lentils and cereal grain.
- Monoamine Oxidase A (MAOA)** Is an isozyme of monoamine oxidase. It preferentially deaminates norepinephrine (noradrenaline), epinephrine (adrenaline), serotonin and dopamine.
- Monoaminergic** Of or pertaining to neurons that secrete monoamine neurotransmitters (e.g. dopamine, serotonin).
- Monoclonal Antibodies** Are produced by fusing single antibody-forming cells to tumour cells grown in culture.
- Monocyte** Large white blood cell that ingest microbes, other cells and foreign matter.
- Monogalactosyl Diglyceride** Are the major lipid components of chloroplasts.
- Monorrhagia** Is heavy bleeding and that is usually defined as periods lasting longer than 7 days or excessive bleeding.
- Morbidity** A diseased state or symptom or can refer either to the incidence rate or to the prevalence rate of a disease.
- Morelloflavone** A biflavonoid extracted from *Garcinia dulcis*, has shown antioxidative, antiviral and antiinflammatory properties.
- Morphine** The major alkaloid of opium and a potent narcotic analgesic.
- mTOR, the Mammalian (or Mechanistic) Target of Rapamycin** Regulates a wide range of cellular and developmental processes by coordinating signalling responses to mitogens, nutrients and various stresses.
- MTTP** Microsomal triglyceride transfer protein that is required for the assembly and secretion of triglyceride-rich lipoproteins from both enterocytes and hepatocytes.
- MUC 5AC** Mucin 5AC, a secreted gel-forming protein mucin with a high molecular weight of about 641 kDa.
- Mucositis** Painful inflammation and ulceration of the mucous membranes lining the digestive tract.
- Mucous** Relating to mucus.
- Mucolytic** Capable of reducing the viscosity of mucus or an agent that so acts.
- Mucus** Viscid secretion of the mucous membrane.
- Multidrug Resistance (MDR)** Ability of a living cell to show resistance to a wide variety of structurally and functionally unrelated compounds.
- Muscarinic Receptors** Are G protein-coupled acetylcholine receptors found in the plasma membranes of certain neurons and other cells.
- Mutagen** An agent that induces genetic mutation by causing changes in the DNA.
- Mutagenic** Capable of inducing mutation (used mainly for extracellular factors such as X-rays or chemical pollution).
- Myalgia** Muscle pain.
- Myc** Codes for a protein that binds to the DNA of other genes and is therefore a transcription factor, found on chromosome 8 in human.
- Mycosis** An infection or disease caused by a fungus.
- Myelocyte** Is a young cell of the granulocytic series, occurring normally in bone marrow, but not in circulating blood.
- Myeloid Leukaemia (Chronic)** A type of cancer that affects the blood and bone marrow, characterized by excessive number of white blood cells.
- Myeloma** Cancer that arise in the plasma cells a type of white blood cells.
- Myeloperoxidase (MPO)** Is a peroxidase enzyme most abundantly present in neutrophil

granulocytes (a subtype of white blood cells). It is an inflammatory enzyme produced by activated leukocytes that predicts risk of coronary heart disease.

Myeloproliferative Disorder Disease of the bone marrow in which excess cells are produced.

Myelosuppressive Causing bone marrow suppression.

Myelotoxicity State of being toxic to myeloid tissues, the bone marrow.

Myocardial Relating to heart muscles tissues.

Myocardial infarction (MI) Is the rapid development of myocardial necrosis caused by a critical imbalance between oxygen supply and demand of the myocardium.

Myocardial Ischemia An intermediate condition in coronary artery disease during which the heart tissue is slowly or suddenly starved of oxygen and other nutrients.

Myocardial Lipidosis Is the accumulation of fat droplets in myocardial fibres.

Myoclonus Brief, involuntary twitching of a muscle or a group of muscles.

Myogenesis The formation of muscular tissue, especially during embryonic development.

Myopathy A muscular disease wherein the muscle fibres do not function for any one of many reasons, resulting in muscular weakness.

Myopia Near or short sightedness.

Myosarcoma A malignant muscle tumour.

Myotonia Dystrophica An inherited disorder of the muscles and other body systems characterized by progressive muscle weakness, prolonged muscle contractions (myotonia), clouding of the lens of the eye (cataracts), cardiac abnormalities, balding and infertility.

Myotube A developing skeletal muscle fibre or cell with a tubular appearance and a centrally located nucleus.

Myringosclerosis Also known as tympanosclerosis or intratympanic tympanosclerosis, is a condition caused by calcification of collagen tissues in the tympanic membrane of the middle ear.

Myotonia A symptom of certain neuromuscular disorders characterized by the slow relaxation of the muscles after voluntary contraction or electrical stimulation.

Myotube A developing skeletal muscle fibre with a tubular appearance.

N-NitrosomorpholineA human carcinogen.

N-NitrosoprolineAn indicator for N-nitrosation of amines.

Nicotinamide Adenine Dinucleotide Phosphate (NADP) A coenzyme comprising nicotinamide mononucleotide coupled by pyrophosphate linkage to adenosine 2',5'-bisphosphate; it acts as an electron carrier in numerous reactions, being alternately oxidized (NADP+) and reduced (NADPH).

NADPH The reduced form of nicotinamide adenine dinucleotide phosphate that serves as an electron carrier.

NAFLD Non-alcoholic fatty liver disease.

Narcotic An agent that produces narcosis; in moderate doses it dulls the senses, relieves pain and induces sleep, and in excessive dose it cause stupor, coma, convulsions and death.

Nasopharynx Upper part of the alimentary continuous with the nasal passages.

Natriorexia Excessive intake of sodium evoked by sodium depletion. *Adj.* natriorexic, natriorexigenic.

Natriuresis The discharge of excessive large amount of sodium through urine. *Adj.* natriuretic.

Natural Killer Cells (NK Cells) A type of cytotoxic lymphocyte that constitutes a major component of the innate immune system.

Natural Killer T (NKT) Cells A heterogeneous group of T cells that share properties of both T cells and natural killer (NK) cells.

Nausea Sensation of unease and discomfort in the stomach with an urge to vomit.

Necropsy See Autopsy.

Necrosis Morphological changes that follow cell death, usually involving nuclear and cytoplasmic changes.

Neointima A new or thickened layer of arterial intima formed especially on a prosthesis or in atherosclerosis by migration and proliferation of cells from the media.

Neonatal *Adj.* of or relating to newborn infants or an infant.

Neoplasia Abnormal growth of cells, which may lead to a neoplasm or tumour.

- Neoplasm** Tumour, any new and abnormal growth, specifically one in which cell multiplication is uncontrolled and progressive. Neoplasms may be benign or malignant.
- Neoplastic Transformation** Conversion of a tissue with a normal growth pattern into a malignant tumour.
- Neovascularization** Is the development of tiny, abnormal, leaky blood vessels inside the eye.
- Neovasculature** Formation of new blood vessels.
- Nephrectomized** Kidneys surgically removed.
- Nephrectomy** Surgical removal of the kidney.
- Nephric** Relating to or connected with a kidney.
- Nephrin** Is a protein necessary for the proper functioning of the renal filtration barrier.
- Nephritic Syndrome** Is a collection of signs (known as a syndrome) associated with disorders affecting the kidneys, more specifically glomerular disorders.
- Nephritis** Is inflammation of the kidney.
- Nephrolithiasis** Process of forming a kidney stone in the kidney or lower urinary tract.
- Nephropathy** A disorder of the kidney.
- Nephrotic Syndrome** Nonspecific disorder in which the kidneys are damaged, causing them to leak large amounts of protein from the blood into the urine.
- Nephrotoxicity** Poisonous effect of some substances, both toxic chemicals and medication, on the kidney.
- Nerve Growth Factor (NGF)** A small protein that induces the differentiation and survival of particular target neurons (nerve cells).
- Nervine** A nerve tonic that acts therapeutically upon the nerves, particularly in the sense of a sedative that serves to calm ruffled nerves.
- Neural Tube Defects (NTDs)** Are common birth defects of the brain and spinal cord.
- NEU 4 Sialidase** This protein belongs to a family of glycohydrolytic enzymes, which remove terminal sialic acid residues from various sialo derivatives, such as glycoproteins, glycolipids, oligosaccharides and gangliosides.
- Neuralgia** Is a sudden, severe painful disorder of the nerves.
- Neuraminidase** Glycoside hydrolase enzymes that cleaves the glycosidic linkages of neuraminic acids.
- Neuraminidase Inhibitors** A class of antiviral drugs targeted at the influenza viruses whose mode of action consists of blocking the function of the viral neuraminidase protein, thus preventing the virus from reproducing.
- Neurasthenia** A condition with symptoms of fatigue, anxiety, headache, impotence, neuralgia and impotence.
- Neurasthenic** A substance used to treat nerve pain and/or weakness (i.e. neuralgia and sciatica).
- Neurite** Refers to any projection from the cell body of a neuron.
- Neuritis** An inflammation of the nerve characterized by pain, sensory disturbances and impairment of reflexes. *Adj.* neuritic.
- Neuritogenesis** The first step of neuronal differentiation and takes place as nascent neurites bud from the immediate postmitotic neuronal soma.
- Neuroblastoma** A common extracranial cancer that forms in nerve tissues, common in infancy.
- Neuroendocrine** *Adj.* of, relating to or involving the interaction between the nervous system and the hormones of the endocrine glands.
- Neurogenesis** Process by which neurons are generated from neural stem and progenitor cells.
- Neurogenic** Originating from the nerves of the nervous system.
- Neuroleptic** Refers to the effects on cognition and behaviour of antipsychotic drugs that reduce confusion, delusions, hallucinations and psychomotor agitation in patients with psychoses.
- Neuroma** Is a growth or tumour of nerve tissue.
- Neuropathy** A collection of disorders that occurs when the peripheral nervous systems are damaged, causing pain and numbness in the hands and feet.
- Neuropharmacological** Relating the effects of drugs on the neurosystem.
- Neuroradiology** Is a subspecialty of radiology focusing on the diagnosis and characterization of abnormalities of the central and peripheral nervous system. *Adj.* neuroradiologic.
- Neurotrophic** Relating to neurotrophs, i.e. the nutrition and maintenance of nervous tissue.
- Neutropenia** A disorder of the blood, characterized by abnormally low levels of neutrophils.

- Neutrophil** Type of white blood cell, specifically a form of granulocyte.
- Neurotrophin** Protein that induce the survival, development and function of neurons.
- NF-kappa B (NF-κB)** Nuclear factor kappa B, is an ubiquitous rapid response transcription factor in cells involved in immune and inflammatory reactions.
- Niacin** Vitamin B3. See Vitamin B3.
- Niacinamide** An amide of niacin, also known as nicotinamide. See Vitamin B3.
- NIH3T3 Cells** A mouse embryonic fibroblast cell line used in the cultivation of keratinocytes.
- Nidation** Implantation.
- Niosomes** Are novel, vesicular, drug delivery systems composed of nonionic surfactants instead of phospholipids; they are capable of entrapping hydrophilic and hydrophobic drugs.
- Nitrogen (N)** Is an essential building block of amino and nucleic acids and proteins and is essential to all living organisms. Protein-rich vegetables like legumes are rich food sources of nitrogen.
- NK Cells** Natural killer cells. A type of cytotoxic lymphocyte that constitutes a major component of the innate immune system.
- NK1.1+ T (NKT) cells** A type of natural killer T (NKT) cells. See Natural Killer T Cells.
- NMDA Receptor** N-methyl-D-ASPARTATE receptor. The predominant molecular device for controlling synaptic plasticity and memory function. A brain receptor activated by the amino acid glutamate, which when excessively stimulated may cause cognitive defects in Alzheimer's disease.
- Nociceptive** Causing pain, responding to a painful stimulus.
- Nociceptors** Specialized peripheral sensory neurons that respond to potentially damaging stimuli by sending nerve signals to the spinal cord and brain.
- Non-osteogenicFibromata** of bone, a benign tumour of bone which shows no evidence of ossification.
- Non-alcoholic Fatty Liver Disease** One cause of a fatty liver, occurring when fat is deposited (steatosis) in the liver not due to excessive alcohol use.
- Nootropics** Are substances which are claimed to boost human cognitive abilities (the functions and capacities of the brain). Also popularly referred to as 'smart drugs', 'smart nutrients', 'cognitive enhancers' and 'brain enhancers'.
- Noradrenalin** See Norepinephrine.
- Norepinephrine** A substance, both a hormone and neurotransmitter, secreted by the adrenal medulla and the nerve endings of the sympathetic nervous system to cause vasoconstriction and increases in heart rate, blood pressure and the sugar level of the blood. Also called levarterenol, noradrenalin.
- Normoglycaemic** Having the normal amount of glucose in the blood.
- Normotensive** Having normal blood pressure.
- Nosebo** A harmless substance that when taken by a patient is associated with unpleasant or harmful effects due to negative expectations or the psychological state of the person.
- Nosocomial Infections** Infections which are a result of treatment in a hospital or a healthcare service unit, but secondary to the patient's original condition.
- NPC1L1** Niemann–Pick C1-like 1 gene that plays a major role in cholesterol homeostasis. It is critical for the uptake of cholesterol across the plasma membrane of the intestinal enterocyte.
- Nrf2** NF-E2-related factor 2, a transcription factor that activates ARE-containing genes.
- Nrf2/ARE Pathway** Plays an important role in inducing phase II detoxifying enzymes and antioxidant proteins and has been considered a potential target for cancer chemoprevention because it eliminates harmful reactive oxygen species or reactive intermediates generated from carcinogens.
- Nuclear Factor Erythroid 2-Related Factor 2 (Nrf2)** A transcription factor that plays a major role in response to oxidative stress by binding to antioxidant-responsive elements that regulate many hepatic phase I and II enzymes as well as hepatic efflux transporters.
- Nucleosomes** Fundamental repeating subunits of all eukaryotic chromatin, consisting of a DNA chain coiled around a core of histones.
- Nulliparous** Term used to describe a woman who has never given birth.

Nyctalopia Night blindness, impaired vision in dim light and in the dark, due to impaired function of certain specialized vision cells.

Nystagmus Fast, involuntary movements of the eyes.

Nycturia Excessive urination at night, especially common in older men.

Occludin A novel integral membrane protein localizing at tight junctions. *Cf.* tight junction.

Occlusion Closure or blockage (as of a blood vessel).

Occlusive Peripheral Arterial Disease (PAOD) Also known as peripheral vascular disease (PVD) or peripheral arterial disease (PAD) refers to the obstruction of large arteries not within the coronary, aortic arch vasculature or brain. PVD can result from atherosclerosis, inflammatory processes leading to stenosis, an embolism or thrombus formation.

Oculomotor Nerve The third of 12 paired cranial nerves.

Odds Ratio A statistical measure of effect size, describing the strength of association or nonindependence between two binary data values.

Odontalgia Toothache. *Adj.* odontalgic.

Odontopathy Any disease of the teeth.

Oedema Formerly known as dropsy or hydropsy, is characterized swelling caused by abnormal accumulation of fluid beneath the skin or in one or more cavities of the body. It usually occurs in the feet, ankles and legs, but it can involve the entire body.

Oedematogenic Producing or causing oedema.

Oestrogen Female hormone produced by the ovaries that play an important role in the oestrous cycle in women.

Oestrogen Receptor (ER) Is a protein found in high concentrations in the cytoplasm of breast, uterus, hypothalamus and anterior hypophysis cells; ER levels are measured to determine a breast CA's potential for response to hormonal manipulation.

Oestrogen Receptor Negative (ER-) Tumour is not driven by oestrogen and needs another test to determine the most effective treatment.

Oestrogen Receptor Positive (ER+) Means that oestrogen is causing the tumour to grow

and that the breast cancer should respond well to hormone suppression treatments.

Oestrogenic Relating to oestrogen or producing oestrous.

Oestrous Sexual excitement or heat of female or period of this characterized by changes in the sex organs.

Oligoarthritis An inflammation of two, three or four joints.

Oligonucleosome A series of nucleosomes.

Oligospermia or Oligozoospermia Refers to semen with a low concentration of sperm, commonly associated with male infertility.

Oligoanuria Insufficient urine volume to allow administration of necessary fluids, etc.

Oliguria Decreased production of urine.

Omega-3 Fatty Acids are essential polyunsaturated fatty acids that have in common a final carbon-carbon double bond in the $n-3$ position. Dietary sources of omega-3 fatty acids include fish oil and certain plant/nut oils. The three most nutritionally important omega-3 fatty acids are alpha-linolenic acid, eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA). Research indicates that omega-3 fatty acids are important in health promotion and disease and can help prevent a wide range of medical problems, including cardiovascular disease, depression, asthma and rheumatoid arthritis.

Omega-6 Fatty Acids Are essential polyunsaturated fatty acids that have in common a final carbon-carbon double bond in the $n-6$ position. Omega-6 fatty acids are considered essential fatty acids (EFAs) found in vegetable oils, nuts and seeds. They are essential to human health but cannot be made in the body. Omega-6 fatty acids—found in vegetable oils, nuts and seeds—are a beneficial part of a heart-healthy eating. Omega-6 and omega-3 PUFA play a crucial role in heart and brain function and in normal growth and development. Linoleic acid (LA) is the main omega-6 fatty acid in foods, accounting for 85–90 % of the dietary omega-6 PUFA. Other omega-6 acids include gamma-linolenic acid or GLA, sometimes called gamoleic acid, eicosadienoic acid, arachidonic acid and docosadienoic acid.

- Omega-9 Fatty Acids** Are not essential polyunsaturated fatty acids that have in common a final carbon-carbon double bond in the $n-9$ position. Some $n-9$ s are common components of animal fat and vegetable oil. Two $n-9$ fatty acids important in industry are oleic acid (18:1, $n-9$), which is a main component of olive oil and erucic acid (22:1, $n-9$), which is found in rapeseed, wallflower seed and mustard seed.
- Oncogenes** Genes carried by tumour viruses that are directly and solely responsible for the neoplastic (tumorous) transformation of host cells.
- Oncosis** Accidental cell death. Also referred to as swelling necrosis.
- Ophthalmia** Severe inflammation of eye or the conjunctiva or deeper structures of the eye. Also called ophthalmitis.
- Ophthalmia (Sympathetic)** Inflammation of both eyes following trauma to one eye.
- Ophthalmopathy** An autoimmune disease where the thyroid gland is overactive leading to ocular manifestations.
- Opiate** Drug derived from the opium plant.
- Opioid Receptors** A group of G-protein-coupled receptors located in the brain and various organs that bind opiates or opioid substances.
- Optic Placode** An ectodermal placode from which the lens of the embryonic eye develops. Also called lens placode.
- ORAC (Oxygen Radical Absorbance Capacity)** A method of measuring antioxidant capacities in biological samples.
- Oral Submucous Fibrosis** A chronic debilitating disease of the oral cavity characterized by inflammation and progressive fibrosis of the submucosa tissues.
- Oral Thrush** An infection of yeast fungus, *Candida albicans*, in the mucous membranes of the mouth.
- Orchidectomy** Surgery to remove one or both testicles.
- Orchidectomized** With testis removed.
- Orchitis** An acute painful inflammatory reaction of the testis secondary to infection by different bacteria and viruses.
- Orexigenic** Increasing or stimulating the appetite.
- Orofacial Dyskinesia** Abnormal involuntary movements involving muscles of the face, mouth, tongue, eyes and, occasionally, the neck—may be unilateral or bilateral and constant or intermittent.
- Oropharyngeal** Relating to the oropharynx.
- Oropharynx** Part of the pharynx between the soft palate and the epiglottis.
- Ostealgia, Ostealgie** Pain in the bones. Also called osteodynia.
- Osteoarthritis** Is the deterioration of the joints that becomes more common with age.
- Osteoarthrosis** Chronic noninflammatory bone disease.
- Osteoblast** A mononucleate cell that is responsible for bone formation.
- Osteoblastic** Relating to osteoblasts.
- Osteocalcin** A noncollagenous protein found in bone and dentin. Also referred to as bone gamma-carboxyglutamic acid-containing protein.
- Osteoclasts** A kind of bone cell that removes bone tissue by removing its mineralized matrix.
- Osteoclastogenesis** The production of osteoclasts.
- Osteodynia** Pain in the bone.
- Osteogenic** Derived from or composed of any tissue concerned in bone growth or repair.
- Osteomalacia** Refers to the softening of the bones due to defective bone mineralization.
- Osteomyelofibrosis** A myeloproliferative disorder in which fibrosis and sclerosis finally lead to bone marrow obliteration.
- Osteopenia** Reduction in bone mass, usually caused by a lowered rate of formation of new bone that is insufficient to keep up with the rate of bone destruction.
- Osteoporosis** A disease of bone that leads to an increased risk of fracture.
- Osteoprotegerin** Also called osteoclastogenesis inhibitory factor (OCIF), a cytokine, which can inhibit the production of osteoclasts.
- Osteosarcoma** A malignant bone tumour. Also called osteogenic sarcoma.
- Otalgia** Earache, pain in the ear.
- Otic Placode** A thickening of the ectoderm on the outer surface of a developing embryo from which the ear develops.
- Otitis** Inflammation of the inner or outer parts of the ear.

- Otitis Media** Inflammation of the middle ear.
- Otorrhoea** Running drainage (discharge) exiting the ear.
- Otopathy** Disease of the ear.
- Ovariectomized** With one or two ovaries removed.
- Ovariectomy** Surgical removal of one or both ovaries.
- Oxidation** The process of adding oxygen to a compound, dehydrogenation or increasing the electronegative charge.
- Oxidoreductase Activity** Catalysis of an oxidation-reduction (redox) reaction, a reversible chemical reaction. One substrate acts as a hydrogen or electron donor and becomes oxidized, while the other acts as hydrogen or electron acceptor and becomes reduced.
- Oxygen Radical Absorbance Capacity (ORAC)** A method of measuring antioxidant capacities in biological samples.
- Oxytocic** *Adj.* hastening or facilitating childbirth, especially by stimulating contractions of the uterus.
- Oxytocin** Is a mammalian hormone that also acts as a neurotransmitter in the brain. It is best known for its roles in female reproduction: it is released in large amounts after distension of the cervix and vagina during labour and after stimulation of the nipples, facilitating birth and breastfeeding, respectively.
- Oxyuriasis** Infestation by pinworms.
- Ozoena** Discharge of the nostrils caused by chronic inflammation of the nostrils.
- P13-K** Is a lipid kinase enzyme involved in the regulation of a number of cellular functions such as cell growth, proliferation, differentiation, motility, survival and intracellular trafficking, which in turn are involved in cancer.
- P13-K/AKT Signalling Pathway** Shown to be important for an extremely diverse array of cellular activities—most notably cellular proliferation and survival.
- P21** Also known as cyclin-dependent kinase inhibitor 1 or CDK-interacting protein 1, is a potent cyclin-dependent kinase inhibitor.
- p21waf1/cip1** Encodes a cyclin-dependent kinase inhibitor that is transcriptionally activated by the p53 tumour suppressor gene, transforming growth factor beta 1 (TGF-beta 1), AP2 and other pathways, all regulating apoptosis and the cell cycle.
- P300/CBP** Are transcriptional coactivators that play critical roles in integrating multiple signal-dependent transcription events and may have specific roles in tumour suppression pathways.
- P53** Also known as protein 53 or tumour protein 53, is a tumour suppressor protein that in humans is encoded by the TP53 gene.
- P65 Transcription Factor** Is a protein that in humans is encoded by the RELA gene. Its alternative name is nuclear factor NF-kappa-B p65 subunit.
- P-Glycoprotein (P-gp, ABCB1, MDR1)** A cell membrane-associated drug-exporting protein that transports a variety of drug substrates from cancer cells.
- P-Selectin** Also known as CD62P, GMP-140, LLECAM-3 and PADGEM and is a member of the selectin family. It is expressed by activated platelets and endothelial cells.
- pACREB** Phosphorylated cAMP (adenosine 3'5' cyclic monophosphate)-response element binding protein.
- Palliative** Relieving pain without alleviating the underlying problem.
- Palpebral Ptosis** The abnormal drooping of the upper lid, caused by partial or total reduction in levator muscle function.
- Palpitation** Rapid pulsation or throbbing of the heart.
- Paludism** State of having symptoms of malaria characterized by high fever and chills.
- Pancreatectomized** Having undergone a pancreatectomy.
- Pancreatectomy** Surgical removal of all or part of the pancreas.
- Pancreatitis** Inflammation of the pancreas.
- Pancytopenia** A haematological condition in which there is a reduction in the number of red and white blood cells, as well as platelets.
- Pantothenic Acid** Vitamin B5. See Vitamin B5.
- Papain** A protein-degrading enzyme used medicinally and to tenderize meat.
- Papilloma** A benign epithelial tumour growing outwardly like in fingerlike fronds.

- Papule** A small, solid, usually inflammatory elevation of the skin that does not contain pus.
- Paradontosis** Is the inflammation of gums and other deeper structures, including the bone.
- Paralytic** Person affected with paralysis, pertaining to paralysis.
- Paraoxonase** An enzyme that protects against oxidation of low-density lipoprotein and affects the risk of coronary artery disease.
- Parasitemia** Presence of parasites in blood. *Adj.* parasitemic.
- Parasympathetic Nervous System** Subsystem of the nervous systems that slows the heart rate and increases intestinal and gland activity and relaxes the sphincter muscles.
- Parasympathomimetic** Having an action resembling that caused by stimulation of the parasympathetic nervous system.
- Paraesthesia** A sensation of tingling, burning, pricking or numbness of a person's skin with no apparent long-term physical effect. Also known as 'pains and needles'.
- Parenteral Administration** Administration by intravenous, subcutaneous or intramuscular routes.
- Paresis** A condition characterized by partial loss of movement or impaired movement.
- Paraesthesia** Is an abnormal sensation of the skin, such as burning, numbness, itching, hyperaesthesia (increased sensitivity) or tingling, with no apparent physical cause.
- Parotitis** Inflammation of salivary glands.
- Paroxysm** A sudden outburst of emotion or action, a sudden attack and recurrence or intensification of a disease.
- Paroxysmic** Relating to an abnormal event of the body with an abrupt onset and an equally sudden return to normal.
- PARP** See Poly (ADP-ribose) polymerase.
- Pars Compacta** Is a portion of the substantia nigra (a brain structure located in the midbrain).
- Parturition** Act of childbirth.
- PCAF** P300/CBP-associated factor. A histone acetyl transferase (HAT) that plays a role in regulation of transcription and cell cycle progression and differentiation.
- PCE/PCN Ratio** Polychromatic erythrocyte/normochromatic erythrocyte ratio used as a measure of cytotoxic effects.
- PCNA** Proliferating cell nuclear antigen, an auxiliary protein of DNA polymerase delta involved in modulating eukaryotic DNA replication.
- PDEF** Acronym for prostate-derived ETS factor, an ETS (epithelial-specific E26 transforming sequence) family member that has been identified as a potential tumour suppressor.
- PDGFs** Platelet-derived growth factors constitute a group of growth factors that play a significant role in blood vessel formation and the growth of blood vessels.
- PDGR Receptor (Platelet-Derived Growth Factor Receptor)** Are cell surface tyrosine kinase receptors for members of the platelet-derived growth factor (PDGF) family.
- Pectoral** Pertaining to or used for the chest and respiratory tract.
- pERK** Phosphorylated extracellular signal-regulated kinase, protein kinases involved in many cell functions.
- Peliosis** See Purpura.
- Pellagra** Is a systemic nutritional wasting disease caused by a deficiency of vitamin B3 (niacin).
- Pemphigus Neonatorum** Staphylococcal scalded skin syndrome, a bacterial disease of infants, characterized by elevated vesicles or blebs on a normal or reddened skin.
- Peptic Ulcer** A sore in the lining of the stomach or duodenum, the first part of the small intestine.
- Peptide YY** A short (36 amino acid) pancreatic protein released by cells in the ileum and colon in response to feeding.
- Percutaneous** Pertains to a medical procedure where access to inner organs or tissues is done via needle puncture of the skin.
- Perfusion** To force fluid through the lymphatic system or blood vessels to an organ or tissue.
- Periapical Periodontitis** Is the inflammation of the tissue adjacent to the tip of the tooth's root.
- Perifuse** To flush a fresh supply of bathing fluid around all of the outside surfaces of a small piece of tissue immersed in it.
- Perilipins** Highly phosphorylated adipocyte proteins that are localized at the surface of the lipid droplet.

- Perimenopause** Is the phase before menopause actually takes place, when ovarian hormone production is declining and fluctuating. *Adj.* perimenopausal.
- Periodontal Ligament (PDL)** Is a group of specialized connective tissue fibres that essentially attach a tooth to the bony socket.
- Periodontitis** Is a severe form of gingivitis in which the inflammation of the gums extends to the supporting structures of the tooth. Also called pyorrhoea.
- Peripheral Arterial Disease (PAD)** Is a disease in which plaque builds up in the arteries that carry blood to your head, organs and limbs.
- Peripheral Neuropathy** Refers to damage to nerves of the peripheral nervous system.
- Peripheral Neuropathic Pain (PNP)** Refers to situations where nerve roots or peripheral nerve trunks have been damaged by mechanical and/or chemical stimuli that exceeded the physical capabilities of the nervous system. Symptoms may include pain, paraesthesia, dysaesthesia, spasm, weakness, hypoesthesia or anaesthesia.
- Peripheral Vascular Disease (PVD)** See Peripheral Artery Occlusive Disease.
- Peristalsis** A series of organized, wave-like muscle contractions that occur throughout the digestive tract.
- PERK** A transmembrane protein kinase of the PEK family resident in the endoplasmic reticulum (ER) membrane and is linked to insulin processing.
- Perlingual** Through or by way of the tongue.
- Perniosis** An abnormal reaction to cold that occurs most frequently in women, children and the elderly. Also called chilblains.
- Per Os (P.O.)** Oral administration.
- Peroxisome Proliferator-Activated Receptors (PPARs)** A family of nuclear receptors that are involved in lipid metabolism, differentiation, proliferation, cell death and inflammation.
- Peroxisome Proliferator-Activated Receptor Alpha (PPAR-Alpha)** A nuclear receptor protein, transcription factor and a major regulator of lipid metabolism in the liver.
- Peroxisome Proliferator-Activated Receptor Gamma (PPAR- γ)** A type II nuclear receptor protein that regulates fatty acid storage and glucose metabolism.
- Pertussis** Whooping cough, severe cough.
- Peyer's Patches** Patches of lymphoid tissue or lymphoid nodules on the walls of the ileal-small intestine.
- PGE-2** Prostaglandin E2. A hormonelike substance that is released by blood vessel walls in response to infection or inflammation that acts on the brain to induce fever.
- Phagocytes** Are the white blood cells that protect the body by ingesting (phagocytosing) harmful foreign particles, bacteria and dead or dying cells. *Adj.* phagocytic.
- Phagocytosis** Is process the human body uses to destroy dead or foreign cells.
- Pharmacognosis** The branch of pharmacology that studies the composition, use and history of drugs.
- Pharmacodynamics** Branch of pharmacology dealing with the effects of drugs and the mechanism of their action.
- Pharmacokinetics** Branch of pharmacology concerned with the movement of drugs within the body including processes of absorption, distribution, metabolism and excretion in the body.
- Pharmacopoeia** Authoritative treatise containing directions for the identification of drug samples and the preparation of compound medicines and published by the authority of a government or a medical or pharmaceutical society and in a broader sense is a general reference work for pharmaceutical drug specifications.
- Pharyngitis, Pharyngolaryngitis** Inflammation of the pharynx and the larynx.
- Pharyngolaryngeal** Pertaining to the pharynx and larynx.
- Phase II Drug-Metabolizing Enzymes** Play an important role in biotransformation of endogenous compounds and xenobiotics to more easily excretable forms as well as in the metabolic inactivation of pharmacologically active compounds. Phase II drug-metabolizing enzymes are mainly transferases.
- Phenolics** Class of chemical compounds consisting of a hydroxyl group ($-OH$) bonded directly to an aromatic hydrocarbon group.

- Pheochromocytoma** Is a rare neuroendocrine tumour that usually originates from the adrenal glands' chromaffin cells, causing overproduction of catecholamines, powerful hormones that induce high blood pressure and other symptoms.
- Phlebitis** Is an inflammation of a vein, usually in the legs.
- Phlegm** Abnormally viscid mucus secreted by the mucosa of the respiratory passages during certain infectious processes.
- Phlegmon** A spreading, diffuse inflammation of the soft or connective tissue due to infection by *Streptococci* bacteria.
- Phloroglucinol** A white, crystalline compound used as an antispasmodic, analytical reagent and decalcifier of bone specimens for microscopic examination.
- Phosphatidylglycerol** Is a glycerophospholipid found in pulmonary active surface lipoprotein and consists of a L-glycerol 3-phosphate backbone ester-bonded to either saturated or unsaturated fatty acids on carbons 1 and 2.
- Phosphatidylinositol 3-kinases (PI 3-Kinases or PI3Ks)** A group of enzymes involved in cellular functions such as cell growth, proliferation, differentiation, motility, survival and intracellular trafficking, which in turn are involved in cancer.
- Phosphatidylserine** A phosphoglyceride phospholipid that is one of the key building blocks of cellular membranes, particularly in the nervous system. It is derived from soy lecithin.
- Phosphaturia** A urinary tract condition of excessive urine phosphorus, causing urine to appear cloudy or murky coloured. Also called hypophosphatemia.
- Phosphodiesterases** A diverse family of enzymes that hydrolyze cyclic nucleotides and thus play a key role in regulating intracellular levels of the second messengers cAMP and cGMP and hence cell function.
- Phosphoenolpyruvate C Kinase (PEPCK)** An enzyme in the lyase family used in the metabolic pathway of gluconeogenesis.
- Phospholipase** An enzyme that hydrolyzes phospholipids into fatty acids and other lipophilic substances.
- Phospholipase A2 (PLA2)** A small lipolytic enzyme that releases fatty acids from the second carbon group of glycerol. Plays an essential role in the synthesis of prostaglandins and leukotrienes.
- Phospholipase C** Enzymes that cleaves phospholipase.
- Phospholipase C Gamma (PLC Gamma)** Enzymes that cleave phospholipase in cellular proliferation and differentiation, and its enzymatic activity is upregulated by a variety of growth factors and hormones.
- Phosphorus (P)** Is an essential mineral that makes up 1 % of a person's total body weight and is found in the bones and teeth. It plays an important role in the body's utilization of carbohydrates and fats, in the synthesis of protein for the growth, maintenance and repair of cells and tissues. It is also crucial for the production of ATP, a molecule the body uses to store energy. Main sources are meat and milk; fruits and vegetables provide small amounts.
- Photoaging** Is the term that describes damage to the skin caused by intense and chronic exposure to sunlight resulting in premature aging of the skin.
- Photocarcinogenesis** Represents the sum of a complex of simultaneous and sequential biochemical events that ultimately lead to the occurrence of skin cancer caused by exposure to the sun.
- Photodermatoses** Skin disorders caused by exposure to sunlight.
- Photophobia** Abnormal visual intolerance to light.
- Photopsia** An affection of the eye, in which the patient perceives luminous rays, flashes, coruscations, etc.
- Photosensitivity** Sensitivity towards light.
- Phthisis** An archaic name for tuberculosis.
- Phytohaemagglutinin** A lectin found in plant that is involved in the stimulation of lymphocyte proliferation.
- Phytonutrients** Certain organic components of plants that are thought to promote human health. Fruits, vegetables, grains, legumes, nuts and teas are rich sources of phytonutrients. Phytonutrients are not 'essential' for life. Also called phytochemicals.

- Phytosterols** A group of steroid alcohols, cholesterol-like phytochemicals naturally occurring in plants like vegetable oils, nuts and legumes.
- Piebaldism** Rare autosomal dominant disorder of melanocyte development characterized by distinct patches of skin and hair that contain no pigment.
- Piles** See Haemorrhoids.
- PI3K** Phosphoinositide 3-kinase.
- PI13K/AKT Signalling Pathways** Are involved in the modulation of cell survival, cell cycle progression and cellular growth in cancer.
- Pityriasis Lichenoides** Is a rare skin disorder of unknown aetiology characterized by multiple papules and plaques.
- PKC** Protein kinase C, a membrane-bound enzyme that phosphorylates different intracellular proteins and raised intracellular Ca levels.
- PKC Delta Inhibitors** Protein kinase C delta inhibitors that induce apoptosis of haematopoietic cell lines.
- Placebo** A sham or simulated medical intervention.
- Placode** A platelike epithelial thickening in the embryo where some organ or structure later develops.
- Plantar Verruca** Wart occurring on the sole of the foot.
- Plasma** The yellow-coloured liquid component of blood, in which blood cells are suspended.
- Plasma Kallikrein** A serine protease, synthesized in the liver and circulates in the plasma.
- Plasmalemma** Plasma membrane.
- Plasmin** A proteinase enzyme that is responsible for digesting fibrin in blood clots.
- Plasminogen** The proenzyme of plasmin, whose primary role is the degradation of fibrin in the vasculature.
- Plasminogen Activator Inhibitor-1 (PAI-1)** Also known as endothelial plasminogen activator inhibitor or serpin E1, is a serine protease inhibitor (serpin) that functions as the principal inhibitor of tissue plasminogen activator (tPA) and urokinase (uPA), the activators of plasminogen and hence fibrinolysis (the physiological breakdown of blood clots).
- Plaster** Poultice.
- Platelet-Activating Factor (PAF)** Is an acetylated derivative of glycerophosphorylcholine, released by basophils and mast cells in immediate hypersensitive reactions and macrophages and neutrophils in other inflammatory reactions. One of its main effects is to induce platelet aggregation.
- PLC Gamma** Phospholipase C gamma plays a central role in signal transduction.
- Pleurisy** Is an inflammation of the pleura, the lining of the pleural cavity surrounding the lungs, which can cause painful respiration and other symptoms. Also known as pleuritis.
- Pneumonia** An inflammatory illness of the lung caused by bacteria or viruses.
- Pneumotoxicity** Damage to lung tissues.
- Poliomyelitis** Is a highly infectious viral disease that may attack the central nervous system and is characterized by symptoms that range from a mild non-paralytic infection to total paralysis in a matter of hours. Also called polio or infantile paralysis.
- Poly (ADP-Ribose) Polymerase (PARP)** A protein involved in a number of cellular processes especially DNA repair and programmed cell death.
- Polyarthritis** Is any type of arthritis which involves five or more joints.
- Polychromatic Erythrocyte (PCE)** An immature red blood cell containing RNA that can be differentiated by appropriate staining techniques from a normochromatic erythrocyte (NCE), which lacks RNA.
- Polycystic Kidney Disease** Is a kidney disorder passed down through families in which multiple cysts form on the kidneys, causing them to become enlarged.
- Polycystic Ovary Syndrome** Imbalance of woman's sex hormone. This imbalance may cause changes in menstrual cycle, skin changes, small cysts in the ovary and problem in getting pregnant.
- Polycythaemia** A type of blood disorder characterized by the production of too many red blood cells.
- Polymorphonuclear** Having a lobed nucleus. Used especially of neutrophilic white blood cells.
- Polyneuritis** Widespread inflammation of the nerves.

- Polyneuritis Gallinarum** A nervous disorder in birds and poultry.
- Polyneuropathy** Simultaneous malfunction of many peripheral nerves throughout the body.
- Polyp** A growth that protrudes from a mucous membrane.
- Polyphagia** Medical term for excessive hunger or eating.
- Polyposis** Describes a condition where there are a lot of polyps.
- Polyuria** A condition characterized by the passage of large volumes of urine with an increase in urinary frequency.
- Pomade** A thick oily dressing.
- Porphyrin** Any of a class of water-soluble, nitrogenous biological pigments.
- Postherpetic Neuralgia (PHN)** Is neuralgia (pain in the nerves) caused by the varicella herpes zoster virus. The pain may last for more than a month or more after a shingles infection occurred.
- Postpartum Depression** Depression after pregnancy. Also called postnatal depression.
- Postprandial** After mealtime.
- Potassium (K)** Is an element that is essential for the body's growth and maintenance. It keeps a normal water balance between the cells and body fluids, for cellular enzyme activities and plays an essential role in the response of nerves to stimulation and in the contraction of muscles. Potassium is found in many plant foods and fish (tuna, halibut): chard, mushrooms, spinach, fennel, kale, mustard greens, Brussels sprouts, broccoli, cauliflower, cabbage winter squash, eggplant, cantaloupe, tomatoes, parsley, cucumber, bell pepper, turmeric, ginger root, apricots, strawberries, avocado and banana.
- Poultice** Is a soft moist mass, often heated and medicated, that is spread on cloth over the skin to treat an aching, inflamed or painful part of the body. Also called cataplasm.
- PPARs** Peroxisome proliferator-activated receptors. A group of nuclear receptor proteins that function as transcription factors regulating the expression of genes.
- PR Interval** Is the time (in seconds) from the beginning of the P wave (onset of atrial depolarization) to the beginning of the QRS complex.
- Prebiotics** A category of functional food, defined as non-digestible food ingredients that beneficially affect the host by selectively stimulating the growth and/or activity of one or a limited number of bacteria in the colon and thus improve host health. *Cf.* probiotics.
- Pre-ecampiasiaToxic** condition of pregnancy characterized by high blood pressure, abnormal weight gain, proteinuria and oedema.
- Prenidatory Phase** Pre-implantation phase.
- Prepubertal** Before puberty, pertaining to the period of accelerated growth preceding gonadal maturity.
- Pregnane X Receptor (PXR; NR1I2)** Is a ligand-activated transcription factor that plays a role not only in drug metabolism and transport but also in various other biological processes.
- Pregnenolone** A steroid hormone produced by the adrenal glands, involved in the steroidogenesis of other steroid hormones like progesterone, mineralocorticoids, glucocorticoids, androgens and oestrogens.
- Prenidatory** Referring to the time period between fertilization and implantation.
- Prenylated Flavones** Flavones with an isoprenyl group in the 8-position has been reported to have good antiinflammatory properties.
- Proangiogenic** Promote angiogenesis (formation and development of new blood vessels).
- Probiotication** Enhancement with beneficial probiotic bacteria such as *Lactobacillus* species that can prevent the growth of intestinal pathogenic microflora.
- Probiotics** Are dietary supplements and live microorganisms containing potentially beneficial bacteria or yeasts that are taken into the alimentary system for healthy intestinal functions. *Cf.* prebiotics.
- Proctitis** An inflammation of the rectum that causes discomfort, bleeding and, occasionally, a discharge of mucus or pus.
- Procyanidin** Also known as proanthocyanidin, oligomeric proanthocyanidin, leukocyanidin, leucoanthocyanin, is a class of flavanols found in many plants. It has antioxidant activity and plays a role in the stabilization of collagen and maintenance of elastin.
- Progestational** Of or relating to the phase of the menstrual cycle immediately following

- ovulation, characterized by secretion of progesterone.
- Proglottid** One of the segments of a tapeworm.
- Prognosis** Medical term to describe the likely outcome of an illness.
- Prokinetic** Or gastropromkinetic. Substance that enhances gastrointestinal motility by increasing the frequency of contractions in the small intestine or making them stronger.
- Prolactin** A hormone produced by the pituitary gland. It stimulates the breasts to produce milk in pregnant women. It is also present in males but its role is not well understood.
- Prolapse** A common condition where the bladder, uterus and or bowel protrudes into the vagina.
- Prolapsus** To fall or slip out of place.
- Prolapsus Ani** Eversion of the lower portion of the rectum and protruding through the anus, common in infancy and old age.
- Proliferating Cell Nuclear Antigen (PCNA)**
A new marker to study human colonic cell proliferation.
- Proliferative Vitreoretinopathy (PVR)** A most common cause of failure in retinal reattachment surgery, characterized by the formation of cellular membrane on both surfaces of the retina and in the vitreous.
- Promastigote** The flagellate stage in the development of trypanosomatid protozoa, characterized by a free anterior flagellum.
- Promyelocytic Leukaemia** A subtype of acute myelogenous leukaemia (AML), a cancer of the blood and bone marrow.
- Pro-oxidants** Chemicals that induce oxidative stress, either through creating reactive oxygen species or inhibiting antioxidant systems.
- Prophylaxis** Prevention or protection against disease.
- Proptosis** See Exophthalmos.
- Prostacyclin** A prostaglandin that is a metabolite of arachidonic acid, inhibits platelet aggregation and dilates blood vessels.
- Prostaglandins** A family of C 20 lipid compounds found in various tissues, associated with muscular contraction and the inflammation response such as swelling, pain, stiffness, redness and warmth.
- Prostaglandin E2 (PEG -2)** One of the prostaglandins, a group of hormonelike substances that participate in a wide range of body functions such as the contraction and relaxation of smooth muscle, the dilation and constriction of blood vessels, control of blood pressure and modulation of inflammation.
- Prostaglandin E Synthase** An enzyme that in humans is encoded by the glutathione-dependent PTGES gene.
- Prostanoids** Term used to describe a subclass of eicosanoids (products of COX pathway) consisting of: the prostaglandins (mediators of inflammatory and anaphylactic reactions), the thromboxanes (mediators of vasoconstriction) and the prostacyclins (active in the resolution phase of inflammation).
- Prostate** A gland that surrounds the urethra at the bladder in the male.
- Prostate Cancer** A disease in which cancer develops in the prostate, a gland in the male reproductive system. Symptoms include pain, difficulty in urinating, erectile dysfunction and other symptoms.
- Prostate-Specific Antigen (PSA)** A protein produced by the cells of the prostate gland.
- Protein Kinase C (PKC)** A family of enzymes involved in controlling the function of other proteins through the phosphorylation of hydroxyl groups of serine and threonine amino acid residues on these proteins. PKC enzymes play important roles in several signal transduction cascades.
- Protein Tyrosine Phosphatase (PTP)** A group of enzymes that remove phosphate groups from phosphorylated tyrosine residues on proteins.
- Proteinase** A protease (enzyme) involved in the hydrolytic breakdown of proteins, usually by splitting them into polypeptide chains.
- Proteinuria** Means the presence of an excess of serum proteins in the urine.
- Proteolysis** Cleavage of the peptide bonds in protein forming smaller polypeptides. *Adj.* proteolytic.
- Proteomics** The large-scale study of proteins, particularly their structures and functions.
- Prothrombin** Blood-clotting protein that is converted to the active form, factor IIa or thrombin, by cleavage.
- Prothyroid** Good for thyroid function.

- Protheolithic** Proteolytic; see Proteolysis.
- Proto-oncogene** A normal gene which, when altered by mutation, becomes an oncogene that can contribute to cancer.
- Prurigo** A general term used to describe itchy eruptions of the skin.
- Pruritis** Defined as an unpleasant sensation on the skin that provokes the desire to rub or scratch the area to obtain relief; itch, itching. *Adj.* pruritic.
- PSA** Prostate-specific antigen. A protein which is secreted into ejaculate fluid by the healthy prostate. One of its functions is to aid sperm movement.
- Psoriasis** A common chronic, noncontagious autoimmune dermatosis that affects the skin and joints.
- Psychoactive** Having effects on the mind or behaviour.
- Psychonautics** Exploration of the psyche by means of approaches such as meditation, prayer, lucid dreaming and brain wave entrainment.
- Psychotomimetic** Hallucinogenic.
- Psychotropic** Capable of affecting the mind, emotions and behaviour.
- PTEN** Phosphatase and tensin homolog. A tumour suppressor gene.
- Ptosia** Also known as drooping eyelid; caused by weakness of the eyelid muscle and damage to the nerves that control the muscles or looseness of the skin of the upper eyelid.
- Phthisis** Silicosis with tuberculosis.
- Ptosia** Drooping of the upper eye lid.
- PTP** Protein tyrosine phosphatase.
- PTPIB** Protein tyrosine phosphatase 1B.
- Puerperal** Pertaining to childbirth.
- Puerperium** Post-partum period.
- Pulmonary Embolism** A blockage (blood clot) of the main artery of the lung.
- Purgative** A substance used to cleanse or purge, especially causing the immediate evacuation of the bowel.
- Purpura** Is the appearance of red or purple discolorations on the skin that do not blanch on applying pressure. Also called peliosis.
- Purulent** Containing pus discharge.
- Purulent Sputum** Sputum containing, or consisting of, pus.
- Pustule** Small, inflamed, pus-filled lesions.
- Pyelonephritis** An ascending urinary tract infection that has reached the pyelum (pelvis) of the kidney.
- Pyoderma** Bacterial skin infection.
- Pyodermatitis** Refers to inflammation of the skin.
- Pyorrhoea** See Periodontitis.
- Pyretic** Referring to fever.
- Pyrexia** Fever of unknown origin.
- Pyridoxal** A chemical form of vitamin B6. See Vitamin B6.
- Pyridoxamine** A chemical form of vitamin B6. See Vitamin B6.
- Pyridoxine** A chemical form of vitamin B6. See Vitamin B6.
- Pyrolysis** Decomposition or transformation of a compound caused by heat. *Adj.* pyrolytic.
- PYY Peptide** A 36 amino acid peptide secreted by L cells of the distal small intestine and colon that inhibits gastric and pancreatic secretion.
- QT Interval** Is a measure of the time between the start of the Q wave and the end of the T wave in the heart's electrical cycle. A prolonged QT interval is a biomarker for ventricular tachyarrhythmias and a risk factor for sudden death.
- Quorum Sensing (QS)** The control of gene expression in response to cell density, is used by both Gram-negative and Gram-positive bacteria to regulate a variety of physiological functions.
- Radiodermatitis** A skin disease associated with prolonged exposure to ionizing radiation.
- Radiolysis** The dissociation of molecules by radiation.
- Radioprotective** Serving to protect or aiding in protecting against the injurious effect of radiations.
- RAGE** Is the receptor for advanced glycation end products, a multiligand receptor that propagates cellular dysfunction in several inflammatory disorders, in tumours and in diabetes.
- RAS** See Renin-Angiotensin System or Recurrent Aphthous Stomatitis.
- Rash** A temporary eruption on the skin; see Urticaria.
- Reactive Oxygen Species** Species such as superoxide, hydrogen peroxide and hydroxyl

radical. At low levels, these species may function in cell signalling processes. At higher levels, these species may damage cellular macromolecules (such as DNA and RNA) and participate in apoptosis (programmed cell death).

Rec A Is a 38 kDa *Escherichia coli* protein essential for the repair and maintenance of DNA.

Receptor for Advanced Glycation End Products (RAGE) Is a member of the immunoglobulin superfamily of cell surface molecules; mediates neurite outgrowth and cell migration upon stimulation with its ligand, amphoterin.

Reticulocyte Nonnucleated stage in the development of the red blood cell.

Reticulocyte Lysate Cell lysate produced from reticulocytes, used as an in-vitro translation system.

Reticuloendothelial System Part of the immune system, consists of the phagocytic cells located in reticular connective tissue, primarily monocytes and macrophages.

Recurrent Aphthous Stomatitis or RAS Is a common, painful condition in which recurring ovoid or round ulcers affect the oral mucosa.

Redox Homeostasis Is considered as the cumulative action of all free radical reactions and antioxidant defenses in different tissues.

Refrigerant A medicine or an application for allaying heat, fever or its symptoms.

Renal Calculi Kidney stones.

Renal Interstitial Fibrosis Damage sustained by the kidneys' renal tubules and interstitial capillaries due to accumulation of extracellular waste in the wall of the small arteries and arterioles.

Renal Resistive Index (RRI) Measures the resistance of renal arterial flow to the kidney.

Renin Also known as an angiotensinogenase, is an enzyme that participates in the body's renin-angiotensin system (RAS).

Renin-Angiotensin System (RAS) Also called the renin-angiotensin-aldosterone system (RAAS), is a hormone system that regulates blood pressure and water (fluid) balance.

Reperfusion The restoration of blood flow to an organ or tissue that has had its blood supply cut-off, as after a heart attack.

Reporter Gene A transfected gene that produces a signal, such as green fluorescence, when it is expressed.

Resistin A cysteine-rich protein secreted by adipose tissue of mice and rats.

Resolutive A substance that induces subsidence of inflammation.

Resolvent Reduces inflammation or swelling.

Resorb To absorb or assimilate a product of the body such as an exudates or cellular growth.

Restenosis Is the reoccurrence of stenosis, a narrowing of a blood vessel, leading to restricted blood flow.

Resveratrol Is a phytoalexin produced naturally by several plants when under attack by pathogens such as bacteria or fungi. It is a potent antioxidant found in red grapes and other plants.

Retinal Ischemia Is a common cause of visual impairment and blindness.

Retinol A form of vitamin A; see Vitamin A.

Retinopathy A general term that refers to some form of non-inflammatory damage to the retina of the eye.

Revulsive Counterirritant, used for swellings.

Rhabdomyolysis Breakdown of muscle fibres leading to the release of muscle fibre content (myoglobin) into the bloodstream.

Rheumatic Pertaining to rheumatism or to abnormalities of the musculoskeletal system.

Rheumatism, Rheumatic Disorder, Rheumatic Diseases Refers to various painful medical conditions which affect bones, joints, muscles and tendons. Rheumatic diseases are characterized by the signs of inflammation—redness, heat, swelling and pain.

Rheumatoid Arthritis (RA) Is a chronic, systemic autoimmune disorder that most commonly causes inflammation and tissue damage in joints (arthritis) and tendon sheaths, together with anaemia.

Rhinitis Irritation and inflammation of some internal areas of the nose and the primary symptom of rhinitis is a runny nose.

Rhinopathy Disease or malformation of the nose.

Rhinoplasty Is surgery to repair or reshape the nose.

- Rhinorrhoea** Commonly known as a runny nose, characterized by an unusually significant amount of nasal discharge.
- Rhinosinusitis** Inflammation of the nasal cavity and sinuses.
- Rho GTPases** Rho-guanosine triphosphate hydrolase enzymes are molecular switches that regulate many essential cellular processes, including actin dynamics, gene transcription, cell-cycle progression and cell adhesion.
- Ribosome Inactivating Proteins** Proteins that are capable of inactivating ribosomes.
- Rickets** Is a softening of the bones in children potentially leading to fractures and deformity.
- Ringworm** Dermatophytosis, a skin infection caused by fungus.
- Roborant** Restoring strength or vigour, a tonic.
- Rotavirus** The most common cause of infectious diarrhoea (gastroenteritis) in young children and infants, one of several viruses that causes infections called stomach flu.
- Rubefacient** A substance for external application that produces redness of the skin, e.g. by causing dilation of the capillaries and an increase in blood.
- Ryanodine receptor** Intracellular Ca^{++} channels in animal tissues like muscles and neurons.
- SC** Abbreviation for subcutaneous, beneath the layer of skin.
- S-T Segment** The portion of an electrocardiogram between the end of the QRS complex and the beginning of the T wave. Elevation or depression of the S-T segment is the characteristics of myocardial ischemia or injury and coronary artery disease.
- Salve** Medical ointment used to soothe the head or body surface.
- Sapraemia** See Septicaemia.
- Sarcoma** Cancer of the connective or supportive tissue (bone, cartilage, fat, muscle, blood vessels) and soft tissues.
- Sarcopenia** Degenerative loss of skeletal muscle mass and strength associated with aging.
- Sarcoplasmic Reticulum** A special type of smooth endoplasmic reticulum found in smooth and striated muscle.
- SARS** Severe acute respiratory syndrome. The name of a potentially fatal new respiratory disease in humans which is caused by the SARS coronavirus (SARS-CoV).
- Satiety** State of feeling satiated, fully satisfied (appetite or desire).
- Scabies** A transmissible ectoparasite skin infection characterized by superficial burrows, intense pruritus (itching) and secondary infection.
- Scarlatina** Scarlet fever, an acute, contagious disease caused by infection with group A streptococcal bacteria.
- Schwann Cells** Or neurolemmocytes, are the principal supporting cells of the peripheral nervous system; they form the myelin sheath of a nerve fibre.
- Schistosomiasis** Is a parasitic disease caused by several species of fluke of the genus *Schistosoma*. Also known as bilharzia, bilharziosis or snail fever.
- Schizophrenia** A psychotic disorder (or a group of disorders) marked by severely impaired thinking, emotions and behaviours.
- Sciatica** a condition characterized by pain deep in the buttock often radiating down the back of the leg along the sciatic nerve.
- Scleroderma** a disease of the body's connective tissue. The most common symptom is a thickening and hardening of the skin, particularly of the hands and face.
- Scrofula** A tuberculous infection of the skin on the neck caused by the bacterium *Mycobacterium tuberculosis*.
- Scrophulosis** See Scrofula.
- Scurf** Abnormal skin condition in which small flakes or scales become detached.
- Scurvy** A state of dietary deficiency of vitamin C (ascorbic acid) which is required for the synthesis of collagen in humans.
- Secretagogue** A substance that causes another substance to be secreted.
- Sedative** Having a soothing, calming or tranquilizing effect; reducing or relieving stress, irritability or excitement.
- Seizure** The physical findings or changes in behaviour that occur after an episode of abnormal electrical activity in the brain.
- Selectins** Are a family of cell adhesion molecules, e.g. selectin-E, selectin-L, selectin-P.

Selenium (Se) A trace mineral that is essential to good health but required only in tiny amounts; it is incorporated into proteins to make selenoproteins, which are important antioxidant enzymes. It is found in avocado, brazil nut, lentils, sunflower seeds, tomato, whole grain cereals, seaweed, seafood and meat.

Sensorineural Bradyacusia Hearing impairment of the inner ear resulting from damage to the sensory hair cells or to the nerves that supply the inner ear.

Sepsis A condition in which the body is fighting a severe infection that has spread via the bloodstream.

Sequela An abnormal pathological condition resulting from a disease, injury or trauma.

Serine Proteinase Peptide hydrolases which have an active centre histidine and serine involved in the catalytic process.

Serotonergic Liberating, activated by or involving serotonin in the transmission of nerve impulses.

Serotonin A monoamine neurotransmitter synthesized in serotonergic neurons in the central nervous system.

Sepsis Is a potentially fatal medical condition characterized by a whole-body inflammatory response (called a systemic inflammatory response syndrome or SIRS) that is triggered by an infection.

Septicaemia A systemic disease associated with the presence and persistence of pathogenic microorganisms or their toxins in the blood.

Sequelae A pathological condition resulting from a prior disease, injury or attack.

Sexual Potentiator Increases sexual activity and potency and enhances sexual performance due to increased blood flow and efficient metabolism.

Sexually Transmitted Diseases (STD) Infections that are transmitted through sexual activity.

SGOT, Serum Glutamic Oxaloacetic Transaminase An enzyme that is normally present in liver and heart cells. SGOT is released into blood when the liver or heart is damaged. Also called aspartate transaminase (AST).

SGPT, Serum Glutamic Pyruvic Transaminase An enzyme normally present in

serum and body tissues, especially in the liver; it is released into the serum as a result of tissue injury. Also called Alanine transaminase (ALT).

Shiga-Like Toxin A toxin produced by the bacterium *Escherichia coli* which disrupts the function of ribosomes. Also known as verotoxin.

Shiga Toxigenic *Escherichia coli* (STEC) Comprises a diverse group of organisms capable of causing severe gastrointestinal disease in humans.

Shiga Toxin A toxin produced by the bacterium *Shigella dysenteriae*, which disrupts the function of ribosomes.

Shingles Skin rash caused by the Zoster virus (same virus that causes chicken pox) and is medically termed herpes zoster.

Sialogogue Salivation promoter, a substance used to increase or promote the excretion of saliva.

Sialoproteins Glycoproteins that contain sialic acid as one of their carbohydrates.

Sialylation Reaction with sialic acid or its derivatives; used especially with oligosaccharides.

Sialyltransferases Enzymes that transfer sialic acid to nascent oligosaccharide.

Sickle-Cell Disease Is an inherited blood disorder that affects red blood cells. People with sickle-cell disease have red blood cells that contain mostly haemoglobin S, an abnormal type of haemoglobin. Sometimes these red blood cells become sickle shaped (crescent shaped) and have difficulty passing through small blood vessels.

Side Stitch Is an intense stabbing pain under the lower edge of the ribcage that occurs while exercising.

Signal Transduction Cascade Refers to a series of sequential events that transfer a signal through a series of intermediate molecules until final regulatory molecules, such as transcription factors, are modified in response to the signal.

Silicon (Si) Is required in minute amounts by the body and is important for the development of healthy hair and the prevention of nervous disorders. Lettuce is the best natural source of Silicon.

- Sinapism** Signifies an external application, in the form of a soft plaster, or poultice.
- Sinusitis** Inflammation of the nasal sinuses.
- SIRC Cells** Statens Serum Institut Rabbit Cornea (SIRC) cell line.
- SIRT 1** Stands for sirtuin (silent mating type information regulation 2 homolog) 1. It is an enzyme that deacetylates proteins that contribute to cellular regulation.
- Sirtuin** Also called Sir2 proteins a class of proteins that possess either histone deacetylase or mono-ribosyltransferase activity.
- 6-Keto-PGF1 Alpha** A physiologically active and stable hydrolysis product of Epoprostenol, found in nearly all mammalian tissues.
- Skp1 (S-Phase Kinase-Associated Protein 1)** Is a core component of SCF ubiquitin ligases and mediates protein degradation.
- Smads** A family of intracellular proteins that mediate signalling by members of the TGF-beta (transforming growth factor beta) superfamily.
- Smad2/3** A key signalling molecule for TGF-beta.
- Smad7** A TGFβ type 1 receptor antagonist.
- Smallpox** Is an acute, contagious and devastating disease in humans caused by *Variola* virus and have resulted in high mortality over the centuries.
- Snuff** Powder inhaled through the nose.
- SOD** Superoxide dismutase, is an enzyme that repairs cells and reduces the damage done to them by superoxide, the most common free radical in the body.
- Sodium (Na)** Is an essential nutrient required for health. Sodium cations are important in neuron (brain and nerve) function and in influencing osmotic balance between cells and the interstitial fluid and in maintenance of total body fluid homeostasis. Extra intake may cause a harmful effect on health. Sodium is naturally supplied by salt intake with food.
- Soleus Muscle** Smaller calf muscle lower down the leg and under the gastrocnemius muscle.
- Somites** Mesodermal structures formed during embryonic development that give rise to segmented body parts such as the muscles of the body wall.
- Soporific** A sleep-inducing drug.
- SOS Response** A global response to DNA damage in which the cell cycle is arrested and DNA repair and mutagenesis are induced.
- Soyasapogenins** Triterpenoid products obtained from the acid hydrolysis of soyasaponins, designated soyasapogenols A, B, C, D and E.
- Soyasaponins** Bioactive saponin compounds found in many legumes.
- Spasmogenic** Inducing spasm.
- Spasmolytic** Checking spasms; see Antispasmodic.
- Spermatorrhoea** Medically an involuntary ejaculation/drooling of semen usually nocturnal emissions.
- Spermidine** An important polyamine in DNA synthesis and gene expression.
- Spina Bifida** A congenital birth defect caused by the incomplete closing of the embryonic neural tube.
- Sphingolipid** A member of a class of lipids derived from the aliphatic amino alcohol, sphingosine.
- Spleen** Organ that filters blood and prevents infection.
- Spleen Tyrosine Kinase (SYK)** Is an enigmatic protein tyrosine kinase functional in a number of diverse cellular processes such as the regulation of immune and inflammatory responses.
- Splenitis** Inflammation of the spleen.
- Splenocyte** Is a monocyte, one of the five major types of white blood cell, and is characteristically found in the splenic tissue.
- Splenomegaly** Is an enlargement of the spleen.
- Sprain** To twist a ligament or muscle of a joint without dislocating the bone.
- Sprue** Is a chronic disorder of the small intestine caused by sensitivity to gluten, a protein found in wheat and rye and to a lesser extent oats and barley . It causes poor absorption by the intestine of fat, protein, carbohydrates, iron, water and vitamins A, D, E and K.
- Sputum** Matter coughed up and usually ejected from the mouth, including saliva, foreign material, and substances such as mucus or phlegm, from the respiratory tract.
- SREBP-1** See Sterol Regulatory Element-Binding Protein-1.
- Stanch** To stop or check the flow of a bodily fluid like blood from a wound.

- Statin** A type of lipid-lowering drug.
- STAT3** Signal transducer and activator of transcription 3, a transcription factor, plays a key role in many cellular processes such as cell growth and apoptosis.
- Status Epilepticus** Refers to a life-threatening condition in which the brain is in a state of persistent seizure.
- STD** Sexually transmitted disease.
- Steatorrhoea** Is the presence of excess fat in faeces which appear frothy, foul smelling and floats because of the high fat content.
- Steatohepatitis** Liver disease, characterized by inflammation of the liver with fat accumulation in the liver.
- Steatosis** Refers to the deposition of fat in the interstitial spaces of an organ like the liver, fatty liver disease.
- Sterility** Inability to produce offspring. Also called asepis.
- Steroidogenic** Relating to steroidogenesis.
- Steroidogenesis** The production of steroids, as by the adrenal glands.
- Sterol Regulatory Element-Binding Protein-1 (SREBP1)** Is a key regulator of the transcription of numerous genes that function in the metabolism of cholesterol and fatty acids.
- Stimulant** A substance that promotes the activity of a body system or function.
- Stomachic** Digestive stimulant, an agent that stimulates or strengthens the activity of the stomach; used as a tonic to improve the appetite and digestive processes.
- Stomatitis** Oral inflammation and ulcers, may be mild and localized or severe, widespread and painful.
- Stomatology** Medical study of the mouth and its diseases.
- Stool** Faeces.
- Strangury** Is the painful passage of small quantities of urine which are expelled slowly by straining with severe urgency; it is usually accompanied with the unsatisfying feeling of a remaining volume inside and a desire to pass something that will not pass.
- Straub Tail** Condition in which an animal carries its tail in an erect (vertical or nearly vertical) position.
- STREPs** Sterol regulatory element binding proteins, a family of transcription factors that regulate lipid homeostasis by controlling the expression of a range of enzymes required for endogenous cholesterol, fatty acid, triacylglycerol and phospholipid synthesis.
- Stria Terminalis** A structure in the brain consisting of a band of fibres running along the lateral margin of the ventricular surface of the thalamus.
- Striae Gravidarum** A cutaneous condition characterized by stretch marks on the abdomen during and following pregnancy.
- Stricture** An abnormal constriction of the internal passageway within a tubular structure such as a vessel or duct
- Strongyloidiasis** An intestinal parasitic infection in humans caused by two species of the parasitic nematode *Strongyloides*. The nematode or round worms are also called thread worms.
- Styptic** A short stick of medication, usually anhydrous aluminium sulphate (a type of alum) or titanium dioxide, which is used for stanching blood by causing blood vessels to contract at the site of the wound. Also called haemostatic pencil. See Antihæmorrhagic.
- Subarachnoid Haemorrhage** Is bleeding in the area between the brain and the thin tissues that cover the brain.
- Substance P** A neuropeptide that functions as a neurotransmitter and neuromodulator and is associated with the sensation of pain.
- Substantia Nigra** Is a dark-coloured brain structure located in the midbrain that play an important role in reward, addiction and movement.
- Sudatory** Medicine that causes or increases sweating. Also see Sudorific.
- Sudorific** A substance that causes sweating.
- Sulphur** Sulphur is an essential component of all living cells. Sulphur is important for the synthesis of sulphur-containing amino acids, all polypeptides, proteins and enzymes such as glutathione, an important sulphur-containing tripeptide which plays a role in cells as a source of chemical reduction potential. Sulphur is also important for hair formation. Good plant sources are garlic, onion, leeks

and other Alliaceous vegetables, Brassicaceous vegetables like cauliflower, cabbages, Brussels sprout, kale, legumes (beans, green and red gram, soybeans), horse radish, water cress and wheat germ.

Superior Mesenteric Artery (SMA) Arises from the anterior surface of the abdominal aorta, just inferior to the origin of the celiac trunk, and supplies the intestine from the lower part of the duodenum to the left colic flexure and the pancreas.

Superoxidase Mutase (SOD) Antioxidant enzyme.

Suppuration The formation of pus, the act of becoming converted into and discharging pus.

Supraorbital Located above the orbit of the eye.

Sural Nerve Sensory nerve comprising collateral branches off of the common tibial and common fibular nerve.

SYK, Spleen Tyrosine Kinase Is a human protein and gene. SYK plays a similar role in transmitting signals from a variety of cell surface receptors including CD74, Fc Receptor and integrins.

Sympathetic Nervous System The part of the autonomic nervous system originating in the thoracic and lumbar regions of the spinal cord that in general inhibits or opposes the physiological effects of the parasympathetic nervous system, as in tending to reduce digestive secretions or speed up the heart.

Synaptic Plasticity The ability of neurons to change the number and strength of their synapses.

Synaptogenesis The formation of synapses.

Synaptoneurosome Purified synapses containing the pre- and postsynaptic termini.

Synaptosome Isolated terminal of a neuron.

Syncope Fainting, sudden loss of consciousness followed by the return of wakefulness.

Syndactyly Webbed toes, a condition where two or more digits are fused together.

Syneresis Expulsion of liquid from a gel, as contraction of a blood clot and expulsion of liquid.

Syngeneic Genetically identical or closely related, so as to allow tissue transplant; immunologically compatible.

Synovial Lubricating fluid secreted by synovial membranes, as those of the joints.

Synoviocyte Located in the synovial membrane, there are two types: type A cells are more numerous, have phagocytic characteristics and produce degradative enzymes, and type B cells produce synovial fluid, which lubricates the joint and nurtures nourishes the articular cartilage.

Syphilis Is perhaps the best known of all the STDs. Syphilis is transmitted by direct contact with infection sores, called chancres, syphilitic skin rashes or mucous patches on the tongue and mouth during kissing, necking, petting or sexual intercourse. It can also be transmitted from a pregnant woman to a foetus after the fourth month of pregnancy.

System Lupus Erythematosus A long-term autoimmune disorder that may affect the skin, joints, kidneys, brain and other organs. Symptoms may include chest pain, fatigue, fever, hair loss, malaise, mouth sores, sensitivity to sunlight and skin rash (butterfly rash).

Systolic The blood pressure when the heart is contracting. It is specifically the maximum arterial pressure during contraction of the left ventricle of the heart.

T cells Or T lymphocytes, a type of white blood cell that plays a key role in the immune system.

Tachyarrhythmia Any disturbance of the heart rhythm in which the heart rate is abnormally increased.

Tachycardia A false heart rate applied to adults to rates over 100 beats per minute.

Tachykinins Neuropeptide transmitters that are widely distributed and active in the central nervous system and periphery, rapidly acting secretagogues and cause smooth muscle contraction and vasodilation (hypotension).

Tachyphylaxis A decreased response to a medicine given over a period of time so that larger doses are required to produce the same response.

Tachypnea Abnormally fast breathing.

Taenia A parasitic tapeworm or flatworm of the genus, *Taenia*.

Taeniocide An agent that kills tapeworms.

Tardive Dyskinesia A disorder characterized by repetitive, involuntary, purposeless movements in the body such as grimacing, tongue protrusion, lip smacking, puckering and pursing

- of the lips and rapid eye blinking. Rapid, involuntary movements of the limbs, torso and fingers may also occur.
- Tau** Is a class of microtubule-associated protein (MAP) in neuronal and glial cells.
- Tau-1 (Ser198/199/202), pS396 (Ser396), and pS214 (Ser214) Epitopes** Serine phosphorylation sites of tau-1.
- Tau Phosphorylation** Plays an important role in neurodegenerative diseases and regulated by protein kinases and phosphatases.
- TBARS** See Thiobarbituric Acid Reactive Substances.
- T Cell** A type of white blood cell that attacks virus-infected cells, foreign cells and cancer cells.
- TCA Cycle** See Tricarboxylic Acid Cycle.
- TCID50** Median tissue culture infective dose; that amount of a pathogenic agent that will produce pathological change in 50 % of cell cultures.
- Telencephalon** The cerebral hemispheres, the largest divisions of the human brain.
- Teletherapy** A noninvasive procedure using external beam radiotherapy treatments.
- Telomerase** Enzyme that acts on parts of chromosomes known as telomeres.
- Temporomandibular Joint Disorder (TMJD or TMD Syndrome)** A disorder characterized by acute or chronic inflammation of the temporomandibular joint that connects the mandible to the skull.
- Tendonitis** Is inflammation of a tendon.
- Tenesmus** A strong desire to defaecate.
- Teratogen** Is an agent that can cause malformations of an embryo or foetus. *Adj.* teratogenic.
- Testicular Torsion** Twisting of the spermatic cord, which cuts off the blood supply to the testicle and surrounding structures within the scrotum.
- Tetanus** An acute, potentially fatal disease caused by tetanus bacilli multiplying at the site of an injury and producing an exotoxin that reaches the central nervous system producing prolonged contraction of skeletal muscle fibres. Also called lockjaw.
- Tete** Acute dermatitis caused by both bacterial and fungal infection.
- Tetter** Any of a number of skin diseases.
- TGF-Beta** Transforming growth factor beta is a protein that controls proliferation, cellular differentiation and other functions in most cells.
- Th cells or T Helper Cells** A subgroup of lymphocytes that helps other white blood cells in immunologic processes.
- Th 1 Cells** Helper cells that play an important role in the immune system.
- Th 17 Cells** A subset of T helper cells producing interleukin 17.
- Thalassemia Major** Is a genetic blood disorder that causes the body to manufacture an abnormal form of haemoglobin.
- Thelarche** The beginning of secondary (postnatal) breast development, usually occurring at the beginning of puberty in girls.
- Thermogenic** Tending to produce heat, applied to drugs or food (fat burning food).
- Thermogenesis** Is the process of heat production in organisms.
- Thermonociceptors** Or thermal nociceptors, sensory receptors that are stimulated by noxious heat or cold at various temperature.
- Thiobarbituric Acid Reactive Substances (TBARS)** A well-established method for screening and monitoring lipid peroxidation.
- Thixotropy** The property exhibited by certain gels of becoming fluid when stirred or shaken and returning to the semisolid state upon standing.
- 3-β-HSD** Or 3-β-hydroxysteroid dehydrogenase/δ-5-4 isomerase is an enzyme that catalyzes the synthesis of progesterone from pregnenolone.
- Thrombocythaemia** A blood condition characterized by a high number of platelets in the blood.
- Thrombocytopenia** A condition when the bone marrow does not produce enough platelets (thrombocytes) like in leukaemia.
- Thromboembolism** Formation in a blood vessel of a clot (thrombus) that breaks loose and is carried by the bloodstream to plug another vessel. Cf. deep vein thrombosis.
- Thrombogenesis** Formation of a thrombus or blood clot.
- Thrombophlebitis** Occurs when there is inflammation and clot in a surface vein.
- Thromboplastin** An enzyme liberated from blood platelets that converts prothrombin into

thrombin as blood starts to clot. Also called thrombokinasase.

Thrombosis The formation or presence of a thrombus (clot).

Thromboxanes Any of several compounds, originally derived from prostaglandin precursors in platelets that stimulate aggregation of platelets and constriction of blood vessels.

Thromboxane B₂ The inactive product of thromboxane.

Thrombus A fibrinous clot formed in a blood vessel or in a chamber of the heart.

Thrush A common mycotic infection caused by yeast, *Candida albicans*, in the digestive tract or vagina. In children it is characterized by white spots on the tongue.

Thymocytes Are T cell precursors which develop in the thymus.

Thyrotoxicosis Or hyperthyroidism, an overactive thyroid gland, producing excessive circulating free thyroxine and free triiodothyronine, or both.

Tight Junction Associated areas of two cells whose membranes join together forming a virtually impermeable barrier to fluid.

TIMP-3 A human gene belongs to the tissue inhibitor of matrix metalloproteinases (MMP) gene family. See MMP.

Tincture Solution of a drug in alcohol.

Tinea Ringworm, fungal infection on the skin.

Tinea favosa See Favus.

Tinea cruris Ringworm of the groin.

Tinea imbricata (also called Tokelau) An eruption characterized by concentric rings of overlapping scales forming papulosquamous patches scattered over the body; it occurs in tropical climates especially prevalent in south-west Polynesia and is caused by the fungus *Trichophyton concentricum*.

Tinea pedis Fungal infection of the foot. Also called Athletes' foot.

Tinnitus A noise in the ears, as ringing, buzzing, roaring, clicking, etc.

Tisane An herbal infusion used as tea or for medicinal purposes.

Tissue Plasminogen Activator (t-PA) A serine protease involved in the breakdown of blood clots.

TNF Alpha Cachexin or cachectin and formally known as tumour necrosis factor-alpha, a cytokine involved in systemic inflammation. Primary role of TNF is in the regulation of immune cells. TNF is also able to induce apoptotic cell death, to induce inflammation, and to inhibit tumorigenesis and viral replication.

Tocolytics Medications used to suppress premature labour.

Tocopherol Fat-soluble organic compounds belonging to vitamin E group. See Vitamin E.

Tocotrienol Fat-soluble organic compounds belonging to vitamin E group. See Vitamin E.

Tolerogenic Producing immunological tolerance.

Toll-Like Receptors (TLRs) A class of proteins that play a key role in the innate immune system.

Tonic Substance that acts to restore, balance, tone, strengthen or invigorate a body system without overt stimulation or depression.

Tonic Clonic Seizure A type of generalized seizure that affects the entire brain.

Tonsillitis An inflammatory condition of the tonsils due to bacteria, allergies or respiratory problems.

TOP2 A Topoisomerase II alpha enzyme.

Topoisomerases A class of enzymes involved in the regulation of DNA supercoiling.

Topoisomerase Inhibitors A new class of anti-cancer agents with a mechanism of action aimed at interrupting DNA replication in cancer cells.

Total Parenteral Nutrition (TPN) Is a method of feeding that bypasses the gastrointestinal tract.

Toxemia Is the presence of abnormal substances in the blood, but the term is also used for a serious condition in pregnancy that involves hypertension and proteinuria. Also called pre-eclampsia.

Tracheitis Is a bacterial infection of the trachea; also known as bacterial tracheitis or acute bacterial tracheitis.

Trachoma A contagious disease of the conjunctiva and cornea of the eye, producing painful sensitivity to strong light and excessive tearing.

TRAIL Acronym for tumour necrosis factor-related apoptosis-inducing ligand, is a cytokine that preferentially induces apoptosis in tumour cells.

- Tranquilizer** A substance drug used in calming person suffering from nervous tension or anxiety.
- Transaminase** Also called aminotransferase is an enzyme that catalyzes a type of reaction between an amino acid and an α -keto acid.
- Transaminitis** Increase in alanine aminotransferase (ALT) and/or aspartate aminotransferase (AST) to >5 times the upper limit of normal.
- Transcatheter Arterial Chemoembolization (TACE)** Is an interventional radiology procedure involving percutaneous access of to the hepatic artery and passing a catheter through the abdominal artery aorta followed by radiology. It is used extensively in the palliative treatment of unresectable hepatocellular carcinoma (HCC)
- Transcriptional Activators** Are proteins that bind to DNA and stimulate transcription of nearby genes.
- Transcriptional Coactivator PGC-1** A potent transcriptional coactivator that regulates oxidative metabolism in a variety of tissues.
- Transcriptome Profiling** To identify genes involved in peroxisome assembly and function.
- Transforming Growth Factor Beta (TGF- β)** A protein that controls proliferation, cellular differentiation and other functions in most cells.
- Transient Receptor Potential Vanilloid 1 (TRPV1)** Receptor also known as capsaicin receptor and vanilloid receptor, is a Ca²⁺ permeable nonselective cation channel localized on a subset of primary sensory neurons and can be activated by physical and chemical stimuli.
- TRAP 6** Thrombin receptor-activating peptide with 6 amino acids.
- Tremorine** A chemical that produces a tremor resembling Parkinsonian tremor.
- Tremulous** Marked by trembling, quivering or shaking.
- Triacylglycerols** Or triacylglyceride, is a glyceride in which the glycerol is esterified with three fatty acids.
- Tricarboxylic Acid Cycle (TCA Cycle)** A series of enzymatic reactions in aerobic organisms involving oxidative metabolism of acetyl units and producing high-energy phosphate compounds, which serve as the main source of cellular energy. Also called citric acid cycle, Krebs cycle.
- Trichophytosis** Infection by fungi of the genus *Trichophyton*.
- Trigeminal Neuralgia (TN)** Is a neuropathic disorder of one or both of the facial trigeminal nerves, also known as prosopalgia.
- Triglycerides** A type of fat (lipids) found in the blood stream.
- Trismus** Continuous contraction of the muscles of the jaw, specifically as a symptom of tetanus, or lockjaw; inability to open mouth fully.
- TrKB receptor** Also known as TrKB tyrosine kinase, a protein in humans that acts as a catalytic receptor for several neurotrophins.
- Trolox Equivalent** Measures the antioxidant capacity of a given substance, as compared to the standard, Trolox also referred to as TEAC (Trolox equivalent antioxidant capacity).
- Trypanocidal** Destructive to trypanosomes.
- Trypanosomes** Protozoan of the genus *Trypanosoma*.
- Trypanosomiasis** Human disease or an infection caused by a trypanosome.
- Trypsin** An enzyme of pancreatic juice that hydrolyzes proteins into smaller polypeptide units.
- Trypsin Inhibitor** Small protein synthesized in the exocrine pancreas which prevents conversion of trypsinogen to trypsin, so protecting itself against trypsin digestion.
- TRPV1** See Transient Receptor Potential Vanilloid 1.
- Tuberculosis (TB)** Is a bacterial infection of the lungs caused by a bacterium called *Mycobacterium tuberculosis*, characterized by the formation of lesions (tubercles) and necrosis in the lung tissues and other organs.
- Tumorigenesis** Formation or production of tumours.
- Tumour** An abnormal swelling of the body other than those caused by direct injury.
- Tussis** A cough.
- Tympanic Membrane** Eardrum.
- Tympanitis** Infection or inflammation of the inner ear.

- Tympanophonia** Increased resonance of one's own voice, breath sounds, arterial murmurs, etc., noted especially in disease of the middle ear.
- Tympanosclerosis** See Myringosclerosis.
- Tyrosinase** A copper containing enzyme found in animals and plants that catalyzes the oxidation of phenols (such as tyrosine) and the production of melanin and other pigments from tyrosine by oxidation.
- Ubiquitin Ligase** Also called an E3 ubiquitin ligase, is a protein that targets other proteins to be broken down (degraded) within cells.
- UCP1** An uncoupling protein found in the mitochondria of brown adipose tissue used to generate heat by non-shivering thermogenesis.
- UCP-2 Enzyme** Uncoupling protein 2 enzyme. A mitochondrial protein expressed in adipocytes.
- Ulcer** An open sore on an external or internal body surface usually accompanied by disintegration of tissue and pus.
- Ulcerative Colitis** Is one of 2 types of inflammatory bowel disease—a condition that causes the bowel to become inflamed and red.
- Ulemorrhagia** Bleeding of the gums.
- Ulitis** Inflammation of the gums.
- Unguent** Ointment.
- Unilateral Ureteral Obstruction** Unilateral blockage of urine flow through the ureter of 1 kidney, resulting in a backup of urine, distension of the renal pelvis and calyces and hydronephrosis.
- Uraemia** An excess in the blood of urea, creatinine and other nitrogenous end products of protein and amino acids metabolism, more correctly referred to as azotaemia.
- Urethra** Tube conveying urine from the bladder to the external urethral orifice.
- Urethritis** Is an inflammation of the urethra caused by infection.
- Uricemia** An excess of uric acid or urates in the blood.
- Uricosuric** Promoting the excretion of uric acid in the urine.
- Urinary** Pertaining to the passage of urine.
- Urinogenital** Relating to the genital and urinary organs or functions.
- Urodynia** Pain on urination.
- Urokinase** Also called urokinase-type plasminogen (u-PA), is a serine protease enzyme in human urine that catalyzes the conversion of plasminogen to plasmin. It is used clinically as a thrombolytic agent.
- Urokinase-Type Plasminogen (u-PA)** Plays a key role in tumour invasion and metastasis. Also see Urokinase.
- Urolithiasis** Formation of stone in the urinary tract (kidney bladder or urethra).
- Urticant** A substance that causes wheals to form.
- Urticaria** Or hives, is a skin condition, commonly caused by an allergic reaction, that is characterized by raised red skin welts.
- Uterine** Relating to the uterus.
- Uterine Prolapse** Occurs when weakened or damaged muscles and ligaments allow the uterus to slip into the vagina.
- Uterine Relaxant** An agent that relaxes the muscles in the uterus.
- Uterine Stimulant** An agent that stimulates the uterus (and often employed during active childbirth).
- Uterotonic** Giving muscular tone to the uterus.
- Uterotrophic** Causing an effect on the uterus.
- Uterus** Womb.
- Vaginal Dystrophy** A condition in which the outer part of the vagina becomes dry and the skin thickens or thins.
- Vaginitis** Infectious or non-infectious inflammation of the vaginal mucosa.
- Vaginopathy** Any disease of the vagina.
- Vagotomy** The surgical cutting of the vagus nerve to reduce acid secretion in the stomach.
- Vagus nerve** A cranial nerve, that is, a nerve connected to the brain. The vagus nerve has branches to most of the major organs in the body, including the larynx, throat, windpipe, lungs, heart and most of the digestive system.
- Variola** Or smallpox, a contagious disease unique to humans, caused by either of two virus variants, *Variola major* and *Variola minor*. The disease is characterized by fever, weakness and skin eruption with pustules that form scabs that leave scars.
- Varicose Veins** Are veins that have become enlarged and twisted.
- Vasa Vasorum** Is a network of small blood vessels that supply large blood vessels. *Pl.* vasa vasori.

- Vascular Endothelial Growth Factor (VEGF)** A polypeptide chemical produced by cells that stimulates the growth of new blood vessels.
- Vasculogenesis** The process of blood vessel formation occurring by a de novo production of endothelial cells.
- Vasoconstrictor** Drug that causes constriction of blood vessels.
- Vasodilator** Drug that causes dilation or relaxation of blood vessels.
- Vasodilatory** Causing the widening of the lumen of blood vessels.
- Vasomotor Symptoms** Menopausal symptoms characterized by hot flushes and night sweats.
- Vasospasm** Refers to a condition in which blood vessels spasm, leading to vasoconstriction and subsequently to tissue ischemia and death (necrosis).
- VCAM-1 (Vascular Cell Adhesion Molecule-1)** Also known as CD106, contains six or seven immunoglobulin domains and is expressed on both large and small vessels only after the endothelial cells are stimulated by cytokines.
- VEGF** Vascular endothelial growth factor.
- Venereal Disease (VD)** Term given to the diseases syphilis and gonorrhoea.
- Venule** A small vein, especially one joining capillaries to larger veins.
- Vermifuge** A substance used to expel worms from the intestines.
- Verotoxin** A Shiga-like toxin produced by *Escherichia coli*, which disrupts the function of ribosomes, causing acute renal failure.
- Verruca** A contagious and painful wart on the sole of the foot.
- Verruca plana** Is a reddish-brown or flesh-coloured, slightly raised, flat-surfaced, well-demarcated papule on the hand and face. Also called flat wart.
- Verruca vulgaris** Small painless warts on the skin caused by the human papillomavirus.
- Vertigo** An illusory, sensory perception that the surroundings or one's own body are revolving; dizziness.
- Very-Low-Density Lipoprotein (VLDL)** A type of lipoprotein made by the liver. VLDL is one of the five major groups of lipoproteins (chylomicrons, VLDL, intermediate-density lipoprotein, low-density lipoprotein, high-density lipoprotein (HDL)) that enable fats and cholesterol to move within the water-based solution of the bloodstream. VLDL is converted in the bloodstream to low-density lipoprotein (LDL).
- Vesical Calculus** Calculi (stones) in the urinary bladder
- Vesicant** A substance that causes tissue blistering.
- Vestibular** Relating to the sense of balance.
- Vestibular Disorders** Includes symptoms of dizziness, vertigo and imbalance; it can be result from or worsened by genetic or environmental conditions.
- Vestibular System** Includes parts of the inner ear and brain that process sensory information involved with controlling balance and eye movement.
- Vibrissa** Stiff hairs that are located especially about the nostrils.
- Viremia** A medical condition where viruses enter the bloodstream and hence have access to the rest of the body.
- Visceral Fat** Intra-abdominal fat, is located inside the peritoneal cavity, packed in between internal organs and torso.
- Vitamin** Any complex, organic compound, found in various food or sometimes synthesized in the body, required in tiny amounts and are essential for the regulation of metabolism, normal growth and function of the body.
- Vitamin A** Retinol, fat-soluble vitamins that play an important role in vision, bone growth, reproduction, cell division and cell differentiation and help regulate the immune system in preventing or fighting off infections. Vitamin A that is found in colourful fruits and vegetables is called provitamin A carotenoid. They can be made into retinol in the body. Deficiency of vitamin A results in night blindness and keratomalacia.
- Vitamin B1** Also called thiamine, water-soluble vitamins, dissolve easily in water, and in general, are readily excreted from the body they are not readily stored, consistent daily intake is important. It functions as coenzyme in the

metabolism of carbohydrates and branched chain amino acids and other cellular processes. Deficiency results in beri-beri disease.

Vitamin B2 Also called riboflavin, an essential water-soluble vitamin that functions as coenzyme in redox reactions. Deficiency causes ariboflavinosis.

Vitamin B3 Comprises niacin and niacinamide, water-soluble vitamin that function as coenzyme or co-substrate for many redox reactions and is required for energy metabolism. Deficiency causes pellagra.

Vitamin B5 Also called pantothenic acid, a water-soluble vitamin that function as coenzyme in fatty acid metabolism. Deficiency causes paraesthesia.

Vitamin B6 Water-soluble vitamin, exists in three major chemical forms: pyridoxine, pyridoxal and pyridoxamine. Vitamin B6 is needed in enzymes involved in protein metabolism, red blood cell metabolism, efficient functioning of nervous and immune systems and haemoglobin formation. Deficiency causes anaemia and peripheral neuropathy.

Vitamin B7 Also called biotin or vitamin H, an essential water-soluble vitamin, is involved in the synthesis of fatty acids amino acids and glucose, in energy metabolism. Biotin promotes normal health of sweat glands, bone marrow, male gonads, blood cells, nerve tissue, skin and hair. Deficiency causes dermatitis and enteritis.

Vitamin B9 Also called folic acid, an essential water-soluble vitamin. Folate is especially important during periods of rapid cell division and growth such as infancy and pregnancy. Deficiency during pregnancy is associated with birth defects such as neural tube defects. Folate is also important for production of red blood cells and prevent anaemia. Folate is needed to make DNA and RNA, the building blocks of cells. It also helps prevent changes to DNA that may lead to cancer.

Vitamin B12 A water-soluble vitamin, also called cobalamin as it contains the metal cobalt. It helps maintain healthy nerve cells and red blood cells and in DNA production. Vitamin B12 is bound to the protein in food. Deficiency causes megaloblastic anaemia.

Vitamin C Also known as ascorbic acid is an essential water-soluble vitamin. It functions as cofactor for reactions requiring reduced copper or iron metalloenzyme and as a protective antioxidant. Deficiency of vitamin C causes scurvy.

Vitamin D A group of fat-soluble, prohormone vitamin, the two major forms of which are vitamin D2 (or ergocalciferol) and vitamin D3 (or cholecalciferol). Vitamin D obtained from sun exposure, food and supplements is biologically inert and must undergo two hydroxylations in the body for activation. Vitamin D is essential for promoting calcium absorption in the gut and maintaining adequate serum calcium and phosphate concentrations to enable normal growth and mineralization of bone and prevent hypocalcemic tetany. Deficiency causes rickets and osteomalacia. Vitamin D has other roles in human health, including modulation of neuromuscular and immune function, reduction of inflammation and modulation of many genes encoding proteins that regulate cell proliferation, differentiation and apoptosis.

Vitamin E Is the collective name for a group of fat-soluble compounds and exists in eight chemical forms (alpha-, beta-, gamma- and delta-tocopherol and alpha-, beta-, gamma- and delta-tocotrienol). It has pronounced antioxidant activities stopping the formation of reactive oxygen species when fat undergoes oxidation and help prevent or delay the chronic diseases associated with free radicals. Besides its antioxidant activities, vitamin E is involved in immune function, cell signalling, regulation of gene expression and other metabolic processes. Deficiency is very rare but can cause mild haemolytic anaemia in newborn infants.

Vitamin K A group of fat-soluble vitamin and consist of vitamin K1 which is also known as phyloquinone or phytomenadione (also called phytonadione) and vitamin K2 (menaquinone, menatetrenone). Vitamin K plays an important role in blood clotting. Deficiency is very rare but can cause bleeding diathesis.

Vitamin P A substance or mixture of substances obtained from various plant sources, identified

as citrin or a mixture of bioflavonoids, thought to but not proven to be useful in reducing the extent of haemorrhage.

Vitiligo A chronic skin disease that causes loss of pigment, resulting in irregular pale patches of skin. It occurs when the melanocytes, cells responsible for skin pigmentation, die or are unable to function. Also called leucoderma.

Vitreoretinopathy See Proliferative Vitreo-retinopathy.

VLA-4 Very late antigen-4, expressed by most leukocytes, but it is observed on neutrophils under special conditions.

VLDL See Very Low-Density Lipoproteins.

Vomitive Substance that causes vomiting.

Vulnerary Wound healer, a substance used to heal wounds and promote tissue formation.

Vulva-Vaginal Erythema Abnormal redness and inflammation of the skin in the vagina.

Wart An infectious skin tumour caused by a viral infection.

Welt See Wheal.

Wheal A firm, elevated swelling of the skin. Also called a weal or welt.

White fat White adipose tissue (WAT) in mammals, store of energy. Cf. brown fat.

Whitlow Painful infection of the hand involving 1 or more fingers that typically affects the terminal phalanx.

Whooping Cough Acute infectious disease usually in children caused by a *Bacillus* bacterium and accompanied by catarrh of the respiratory passages and repeated bouts of coughing.

Wnt signalling Pathway Is a network of proteins involved in embryogenesis and cancer and also in normal physiological processes.

X-Linked Agammaglobulinemia Also known as X-linked hypogammaglobulinaemia, XLA, Bruton type agammaglobulinemia, Bruton syndrome or sex-linked agammaglobulinemia; a rare x-linked genetic disorder that affects the body's ability to fight infection.

Xanthine Oxidase A flavoprotein enzyme containing a molybdenum cofactor (Moco) and (Fe₂S₂) clusters, involved in purine metabolism. In humans, inhibition of xanthine oxidase reduces the production of uric acid and prevents hyperuricemia and gout.

Xanthones Unique class of biologically active phenol compounds with the molecular formula C₁₃H₈O₂ possessing antioxidant properties, discovered in the mangosteen fruit.

Xenobiotics A chemical (as a drug, pesticide or carcinogen) that is foreign to a living organism.

Xenograft A surgical graft of tissue from one species to an unlike species.

Xerophthalmia A medical condition in which the eye fails to produce tears.

Yaws An infectious tropical infection of the skin, bones and joints caused by the spirochete bacterium *Treponema pertenue*, characterized by papules and papilloma with subsequent deformation of the skins, bone and joints. Also called framboesia.

yGCN5 A histone acetyl transferase (HAT) that plays a role in regulation of transcription, cell cycle progression and differentiation.

Yellow Fever Is a viral disease that is transmitted to humans through the bite of infected mosquitoes. Illness ranges in severity from an influenza-like syndrome to severe hepatitis and haemorrhagic fever. Yellow fever virus (YFV) is maintained in nature by mosquito-borne transmission between nonhuman primates.

Zeaxanthin A common carotenoid, found naturally as coloured pigments in many fruit vegetables and leafy vegetables. It is important for good vision and is one of the two carotenoids contained within the retina of the eye. Within the central macula, zeaxanthin predominates, whereas in the peripheral retina, lutein predominates.

Zinc (Zn) Is an essential mineral for health. It is involved in numerous aspects of cellular metabolism: catalytic activity of enzymes, immune function, protein synthesis, wound healing, DNA synthesis and cell division. It also supports normal growth and development during pregnancy, childhood and adolescence and is required for proper sense of taste and smell. Dietary sources include beans, nuts, pumpkin seeds, sunflower seeds, whole wheat bread and animal sources.

ZO1 Protein A high molecular weight tight junction-associated protein.

Scientific Glossary

- Abaxial** Facing away from the axis, as of the surface of an organ.
- Abortive** Imperfectly formed.
- Abscission** Shedding of leaves, flowers or fruits following the formation of the abscission zone.
- Acaulescent** Lacking a stem or stem very much reduced.
- Accrescent** Increasing in size after flowering or with age.
- Achene** A dry, small, one-seeded, indehiscent one-seeded fruit formed from a superior ovary of one carpel as in sunflower.
- Acid Soil** Soil that maintains a pH of less than 7.0.
- Acidulous** Acid or sour in taste.
- Actinomorphic** Having radial symmetry, capable of being divided into symmetrical halves by any plane, refers to a flower, calyx or corolla.
- Aculeate** Having sharp prickles.
- Acuminate** Tapering gradually to a sharp point.
- Acute (Botany)** Tapering at an angle of less than 90° before terminating in a point as of leaf apex and base.
- Adaxial** Side closest to the stem axis.
- Aldephous** Having stamens united together by their filaments.
- Adherent** Touching without organic fusion as of floral parts of different whorls.
- Adnate** United with another unlike part as of stamens attached to petals.
- Adpressed** Lying close to another organ but not fused to it.
- Adventitious** Arising in abnormal positions, e.g. roots arising from the stem, branches or leaves; buds arising elsewhere than in the axils of leaves.
- Adventive** Not native to and not fully established in a new habitat or environment; locally or temporarily naturalized, e.g. an adventive weed.
- Aestivation** Refers to positional arrangement of the floral parts in the bud before it opens.
- Akinete** A thick-walled dormant cell derived from the enlargement of a vegetative cell. It serves as a survival structure.
- Alfisols** Soil with a clay-enriched subsoil and relatively high native fertility, having undergone only moderate leaching, containing aluminium, iron and with at least 35 % base saturation, meaning that calcium, magnesium and potassium are relatively abundant.
- Alkaline Soil** Soil that maintains a pH above 7.0, usually containing large amounts of calcium, sodium and magnesium and is less soluble than acidic soils.
- Alkaloids** Naturally occurring bitter, complex organic-chemical compounds containing basic nitrogen and oxygen atoms and having various pharmacological effects on humans and other animals.
- Alternate** Leaves or buds that are spaced along opposite sides of stem at different levels.
- Allomorphic** With a shape or form different from the typical.
- Alluvial Soil** A fine-grained fertile soil deposited by water flowing over flood plains or in river beds.
- Alluvium** Soil or sediments deposited by a river or other running water.
- Amplexicaul** Clasping the stem as base of certain leaves.
- Anatomizing** Interconnecting network as applied to leaf veins.

- Andisols** Are soils formed in volcanic ash and containing high proportions of glass and amorphous colloidal materials.
- Androdioecious** With male flowers and bisexual flowers on separate plants.
- Androeceium** Male parts of a flower, comprising the stamens of one flower.
- Androgynophore** A stalk bearing both the androeceium and gynoecium above the perianth of the flower.
- Androgynous** With male and female flowers in distinct parts of the same inflorescence.
- Andromonoecious** Having male flowers and bisexual flowers on the same plant.
- Angiosperm** A division of seed plants with the ovules borne in an ovary.
- Annual** A plant which completes its life cycle within a year.
- Annular** Shaped like or forming a ring.
- Annulus** Circle or ringlike structure or marking; the portion of the corolla which forms a fleshy, raised ring.
- Anthelate** An open, paniculate cyme.
- Anther** The part of the stamen containing pollen sac which produces the pollen.
- Antheriferous** Containing anthers.
- Anthesis** The period between the opening of the bud and the onset of flower withering.
- Anthocarp** A false fruit consisting of the true fruit and the base of the perianth.
- Anthocyanidins** Are common plant pigments. They are the sugar-free counterparts of anthocyanins.
- Anthocyanins** A subgroup of antioxidant flavonoids and are glucosides of anthocyanidins. They occur as water-soluble vacuolar pigments that may appear red, purple or blue according to pH in plants.
- Antipetala** Situated opposite petals.
- Antisepala** Situated opposite sepals.
- Antrorse** Directed forward upwards.
- Apetalous** Lacking petals as of flowers with no corolla.
- Apical meristem** Active growing point. A zone of cell division at the tip of the stem or the root.
- Apically** Towards the apex or tip of a structure.
- Apiculate** Ending abruptly in a short, sharp, small point.
- Apiculum** A short, pointed, flexible tip.
- Apocarpous** Carpels separate in single individual pistils.
- Apopetalous** With separate petals, not united to other petals.
- Aposepalous** With separate sepals, not united to other sepals.
- Appressed** Pressed closely to another structure but not fused or united.
- Aquatic** A plant living in or on water for all or a considerable part of its life span.
- Arachnoid (Botany)** Formed of or covered with long, delicate hairs or fibres.
- Arborescent** Resembling a tree; applied to nonwoody plants attaining tree height and to shrubs tending to become treelike in size.
- Arbuscular Mycorrhiza (AM)** A type of mycorrhiza in which the fungus (of the phylum Glomeromycota) penetrates the cortical cells of the roots of a vascular plant and form unique structures such as arbuscules and vesicles. These fungi help plants to capture nutrients such as phosphorus and micronutrients from the soil.
- Archegonium** A flask-shaped female reproductive organ in mosses, ferns and other related plants.
- Areolate** With areolea.
- Areole (Botany)** A small, specialized, cushion-like area on a cactus from which hairs, glochids, spines, branches or flowers may arise; an irregular angular specs marked out on a surface, e.g. fruit surface. *Pl.* areolea.
- Aril** Specialized outgrowth from the funiculus (attachment point of the seed) (or hilum) that encloses or is attached to the seed. *Adj.* arillate.
- Arillode** A false aril; an aril originating from the micropyle instead of from the funicle or chalaza of the ovule, e.g. mace of nutmeg.
- Aristate** Bristlelike part or appendage, e.g. awns of grains and grasses.
- Aristulate** Having a small, stiff, bristlelike part or appendage; a diminutive of aristate
- Articulate** Jointed; usually breaking easily at the nodes or point of articulation into segments.
- Ascending** Arched upwards in the lower part and becoming erect in the upper part.
- Ascospore** Spore produced in the ascus in Ascomycete fungi.

- Ascus** Is the sexual spore-bearing cell produced in Ascomycete fungi. *Pl.* asci.
- Asperulous** Refers to a rough surface with short, hard projections.
- Attenuate** Tapered or tapering gradually to a point.
- Auricle** An earlike appendage that occurs at the base of some leaves or corolla.
- Auriculate** Having auricles.
- Awn** A hair-like or bristlelike appendage on a larger structure.
- Axil** Upper angle between a lateral organ, such as a leaf petiole and the stem that bears it.
- Axile** Situated along the central axis of an ovary having two or more locules, as in axile placentation.
- Axillary** Arising or growing in an axil.
- Baccate** Beery like, pulpy or fleshy.
- Barbate** Bearded, having tufts of hairs.
- Barbellae** Short, stiff, hair-like bristles. *Adj.* barbellate.
- Bark** Is the outermost layers of stems and roots of woody plants.
- Basal** Relating to, situated at, arising from or forming the base.
- Basaltic Soil** Soil derived from basalt, a common extrusive volcanic rock.
- Basidiospore** A reproductive spore produced by Basidiomycete fungi.
- Basidium** A microscopic, spore-producing structure found on the hymenophore of fruiting bodies of Basidiomycete fungi.
- Basifixed** Attached by the base, as certain anthers are to their filaments.
- Basionym** The synonym of a scientific name that supplies the epithet for the correct name.
- Beak** A prominent apical projection, especially of a carpel or fruit. *Adj.* beaked.
- Bearded** Having a tuft of hairs.
- Berry** A fleshy or pulpy indehiscent fruit from a single ovary with the seed(s) embedded in the fleshy tissue of the pericarp.
- Biconvex** Convex on both sides.
- Biennial** Completing the full cycle from germination to fruiting in more than one, but not more than 2 years.
- Bifid** Forked, divided into two parts.
- Bifoliolate** Having two leaflets.
- Bilabiate** Having two lips as of a corolla or calyx with segments fused into an upper and lower lip.
- Bipinnate** Twice pinnate; the primary leaflets being again divided into secondary leaflets.
- Bipinnatisect** Refers to a pinnately compound leaf, in which each leaflet is again divided into pinnae.
- Biserrate** Doubly serrate; with smaller regular, asymmetric teeth on the margins of larger teeth.
- Bisexual** Having both sexes, as in a flower bearing both stamens and pistil, hermaphrodite or perfect.
- Biternate** Twice ternate; with three pinnae each divided into three pinnules.
- Blade** Lamina; part of the leaf above the sheath or petiole.
- Blotched** See Variegated.
- Bole** Main trunk of tree from the base to the first branch.
- Brachyblast** A short, axillary, densely crowded branchlet or shoot of limited growth, in which the internodes elongate little or not at all.
- Bracket Fungus** Shelf fungus.
- Bract** A leaflike structure, different in form from the foliage leaves, associated with an inflorescence or flower. *Adj.* bracteate.
- Bracteate** Possessing bracts.
- Bracteolate** Having bracteoles.
- Bracteole** A small, secondary, bract-like structure borne singly or in a pair on the pedicel or calyx of a flower. *Adj.* bracteolate.
- Bran** Hard outer layer of grain and comprises the aleurone and pericarp. It contains important antioxidant, vitamins and fibre.
- Bristle** A stiff hair.
- Bulb** A modified underground axis that is short and crowned by a mass of usually fleshy, imbricate scales. *Adj.* bulbous.
- Bulbil** A small bulb or bulb-shaped body, especially one borne in the leaf axil or an inflorescence, and usually produced for asexual reproduction.
- Bullate** Puckered, blistered.
- Burr** Type of seed or fruit with short, stiff bristles or hooks or may refer to a deformed type of wood in which the grain has been misformed.
- Bush** Low, dense shrub without a pronounced trunk.

- Buttress** Supporting, projecting outgrowth from base of a tree trunk as in some Rhizophoraceae and Moraceae.
- Caducous** Shedding or falling early before maturity refers to sepals and petals.
- Caespitose** Growing densely in tufts or clumps; having short, closely packed stems.
- Calcareous** Composed of or containing lime or limestone.
- Calcrete** A hardpan consisting gravel and sand cemented by calcium.
- Callus** A condition of thickened raised mass of hardened tissue on leaves or other plant parts often formed after an injury but sometimes a normal feature. A callus also can refer to an undifferentiated plant cell mass grown on a culture medium. *N.* callosity; *Pl.* calli, callosities; *Adj.* callose.
- Calyptra** The protective cap or hood covering the spore case of a moss or related plant.
- Calyptrate** Operculate, having a calyptra.
- Calyx** Outer floral whorl usually consisting of free sepals or fused sepals (calyx tube) and calyx lobes. It encloses the flower while it is still a bud. *Adj.* calycine.
- Calyx Lobe** One of the free upper parts of the calyx which may be present when the lower part is united into a tube.
- Calyx Tube** The tubular fused part of the calyx, often cup shaped or bell shaped, when it is free from the corolla.
- Campanulate** Shaped like a bell refers to calyx or corolla.
- Canaliculate** Having groove or grooves.
- Candelabrifform** Having the shape of a tall branched candlestick.
- Canescent** Covered with short, fine whitish or greyish hairs or down.
- Canopy** Uppermost leafy stratum of a tree.
- Cap** See Pileus.
- Capitate** Growing together in a head. Also means enlarged and globular at the tip.
- Capitulum** A flower head or inflorescence having a dense cluster of sessile, or almost sessile, flowers or florets.
- Capsule** A dry, dehiscent fruit formed from two or more united carpels and dehiscing at maturity by sections called valves to release the seeds. *Adj.* capsular.
- Carinate** Keeled.
- Carpel** A simple pistil consisting of ovary, ovules, style and stigma. *Adj.* carpellary.
- Carpogonium** Female reproductive organ in red algae. *Pl.* carpogonia.
- Carpophore** Part of the receptacle which is lengthened between the carpels as a central axis; any fruiting body or fruiting structure of a fungus.
- Cartilaginous** Sinewy, having a firm, tough, flexible texture (in respect of leaf margins).
- Caruncle (Botany)** Fleshy structure attached to the seed of certain plants.
- Caryopsis** A simple dry, indehiscent fruit formed from a single ovary with the seed coat united with the ovary wall as in grasses and cereals.
- Cataphyll** A reduced or scarcely developed leaf at the start of a plant's life (i.e. cotyledons) or in the early stages of leaf development.
- Catkin** A slim, cylindrical, pendulous flower spike usually with unisexual flowers.
- Caudate** Having a narrow, tail-like appendage.
- Caudex** Thickened, usually underground base of the stem.
- Caulescent** Having a well-developed aerial stem.
- Cauliflory** Botanical term referring to plants which flower and fruit from their main stems or woody trunks. *Adj.* cauliflorous.
- Cauline** Borne on the aerial part of a stem.
- Chaffy** Having thin, membranous scales in the inflorescence as in the flower heads of the sunflower family.
- Chalaza** The basal region of the ovule where the stalk is attached.
- Chamaephyte** A low-growing perennial plant whose dormant overwintering buds are borne at or just above the surface of the ground.
- Chartaceous** Papery, of paper-like texture.
- Chasmogamous** Describing flowers in which pollination takes place while the flower is open.
- Chatoyant** Having a velvety sheen or lustre.
- Chloroplast** A chlorophyll-containing organelle (plastid) that gives the green colour to leaves and stems. Plastids harness light energy that is used to fix carbon dioxide in the process called photosynthesis.

- Chromoplast** Plastid containing coloured pigments apart from chlorophyll.
- Chromosomes** Thread-shaped structures that occur in pairs in the nucleus of a cell, containing the genetic information of living organisms.
- Cilia** Hairs along the margin of a leaf or corolla lobe.
- Ciliate** With a fringe of hairs on the margin as of the corolla lobes or leaf.
- Ciliolate** Minutely ciliate.
- Cilium** A straight, usually erect hair on a margin or ridge. *Pl.* cilia.
- Cincinnus** A monochasial cyme in which the lateral branches arise alternately on opposite sides of the false axis.
- Circinate** Spirally coiled, with the tip innermost.
- Circumscissile** Opening by a transverse line around the circumference as of a fruit.
- Cladode** The modified photosynthetic stem of a plant whose foliage leaves are much reduced or absent. *Cf.* cladophyll, phyllode.
- Cladophyll** A photosynthetic branch or portion of a stem that resembles and functions as a leaf, like in asparagus. *Cf.* cladode, phyllode.
- Clamp Connection** In the Basidiomycetes fungi, a lateral connection or outgrowth formed between two adjoining cells of a hypha and arching over the septum between them.
- Clavate** Club shaped thickened at one end refer to fruit or other organs.
- Claw** The conspicuously narrowed basal part of a flat structure.
- Clay** A naturally occurring material composed primarily of fine-grained minerals like kaolinite, montmorillonite-smectite or illite which exhibit plasticity through a variable range of water content and which can be hardened when dried and/or fired.
- Clayey** Resembling or containing a large proportion of clay.
- Cleft** Incised halfway down.
- Cleistogamous** Refers to a flower in which fertilization occurs within the bud, i.e. without the flower opening. *Cf.* chasmogamous.
- Climber** Growing more or less upwards by leaning or twining around another structure.
- Clone** All the plants reproduced, vegetatively, from a single parent, thus having the same genetic make-up as the parent.
- Coccus** One of the sections of a distinctly lobed fruit which becomes separate at maturity; sometimes called a mericarp. *Pl.* cocci.
- Coenocarpium** A fleshy, multiple pseudocarp formed from an inflorescence rather than a single flower.
- Coherent** Touching without organic fusion, referring to parts normally together, e.g. floral parts of the same whorl. *Cf.* adherent, adnate, connate.
- Collar** Boundary between the above- and below ground parts of the plant axis.
- Colliculate** Having small elevations.
- Column** A structure formed by the united style, stigma and stamen(s) as in Asclepiadaceae and Orchidaceae.
- Comose** Tufted with hairs at the ends as of seeds.
- Composite** Having two types of florets as of the flowers in the sunflower family, Asteraceae.
- Compost** Organic matter (like leaves, mulch and manure) that breaks down in soil releasing its nutrients.
- Compound** Describes a leaf that is further divided into leaflets or pinnae or flower with more than a single floret.
- Compressed** Flattened in one plane.
- Conceptacles** Specialized cavities of marine algae that contain the reproductive organs.
- Concolorous** Uniformly coloured, as in upper and lower surfaces. *Cf.* discolorous
- Conduplicate** Folded together lengthwise.
- Cone** A reproductive structure composed of an axis (branch) bearing sterile bract-like organs and seed or pollen-bearing structures. Applied to Gymnospermae, Lycopodiaceae, Casuarinaceae and also in some members of Proteaceae.
- Conic** Cone shaped, attached at the broader end.
- Conic-Capitate** A cone-shaped head of flowers.
- Connate** Fused to another structure of the same kind. *Cf.* adherent, adnate, coherent.
- Connective** The tissue separating two lobes of an anther.
- Connivent** Converging.

- Conspecific** Within or belonging to the same species.
- Contorted** Twisted.
- Convolute** Refers to an arrangement of petals in a bud where each has one side overlapping the adjacent petal.
- Cordate** Heart shaped as of leaves.
- Core** Central part.
- Coriaceous** Leathery texture as of leaves.
- Corm** A short, swollen, fleshy, underground plant stem that serves as a food storage organ used by some plants to survive winter or other adverse conditions
- Cormel** A miniature, new corm produced on a mature corm.
- Corn Silk** The long, filamentous styles that grow as a silky tuft or tassel at the tip of an ear of corn.
- Corolla** The inner floral whorl of a flower, usually consisting of free petals or a petals fused forming a corolla tube and corolla lobes. *Adj.* corolline.
- Corona** A crown-like section of the staminal column, usually with the inner and outer lobes as in the **Stapelieae**.
- Coroniform** Crown shaped, as in the pappus of **Asteraceae**.
- Cortex** The outer of the stem or root of a plant, bounded on the outside by the epidermis and on the inside by the endodermis containing undifferentiated cells.
- Corymb** A flat-topped, short, broad inflorescence, in which the flowers, through unequal pedicels, are in one horizontal plane and the youngest in the centre. *Adj.* corymbose.
- Costa** A thickened, linear ridge or the midrib of the pinna in ferns. *Adj.* costate.
- Costapalmate** Having definite costa (midrib) unlike the typical palmate leaf, but the leaflets are arranged radially like in a palmate leaf.
- Cotyledon** The primary seed leaf within the embryo of a seed.
- Cover Crop** Crop grown in between trees or in fields primarily to protect the soil from erosion, to improve soil fertility and to keep off weeds.
- Crenate** Round toothed or scalloped as of leaf margins.
- Crenulate** Minutely crenate, very strongly scalloped.
- Crested** Frilled and ruffled edge.
- Crispate** Weakly undulating edge.
- Crisped** With a curled or twisted edge.
- Cristate** Having or forming a crest or crista.
- Crozier** Shaped like a shepherd's crook.
- Crustaceous** Like a crust, having a hard crust or shell.
- Cucullate** Having the shape of a cowl or hood, hooded.
- Culm** The main aerial stem of the **Gramineae** (grasses, sedges, rushes and other monocots).
- Culm Sheath** The plant casing (similar to a leaf) that protects the young bamboo shoot during growth, attached at each node of culm.
- Cultigen** Plant species or race known only in cultivation.
- Cultivar** Cultivated variety; an assemblage of cultivated individuals distinguished by any characters significant for the purposes of agriculture, forestry or horticulture and which, when reproduced, retains its distinguishing features.
- Cuneate** Wedge shaped, obtriangular.
- Cupular** Cup shaped, having a cupule.
- Cupule** A small cup-shaped structure or organ, like the cup at the base of an acorn.
- Cusp** An elongated, usually rigid, acute point. *Cf.* mucro.
- Cuspidate** Terminating in or tipped with a sharp firm point or cusp. *Cf.* mucronate.
- Cuspidulate** Constricted into a minute cusp. *Cf.* cuspidate.
- Cyathiform** In the form of a cup, a little widened at the top.
- Cyathium** A specialized type of inflorescence of plants in the genus *Euphorbia* and *Chamaesyce* in which the unisexual flowers are clustered together within a bract-like envelope. *Pl.* cyathia.
- Cylindric** Tubular or rod shaped.
- Cylindric-Acuminate** Elongated and tapering to a point.
- Cymbiform** Boat shaped, elongated and having the upper surface decidedly concave.
- Cyme** An inflorescence in which the lateral axis grows more strongly than the main axis with the oldest flower in the centre or at the ends. *Adj.* cymose
- Cymule** A small cyme or one or a few flowers.

- Cystidium** A relatively large cell found on the hymenium of a Basidiomycete, for example, on the surface of a mushroom.
- Cystocarp** Fruitlike structure (sporocarp) developed after fertilization in the red algae.
- Deciduous** Falling off or shedding at maturity or a specific season or stage of growth.
- Decorticate** To remove the bark, rind or husk from an organ; to strip of its bark; to come off as a skin.
- Decomound** As of a compound leaf; consisting of divisions that are themselves compound.
- Decumbent** Prostrate, laying or growing on the ground but with ascending tips. *Cf.* ascending, procumbent.
- Decurrent** Having the leaf base tapering down to a narrow wing that extends to the stem.
- Decussate** Having paired organs with successive pairs at right angles to give four rows as of leaves.
- Deflexed** Bent downwards.
- Degumming** Removal of gum deposits (phosphatides, entrained oil and meal particles) from crude edible oils traditionally done with water. Water degumming process also remove hydrophilic substances such as sugars from the oil.
- Dehisce** To split open at maturity, as in a capsule.
- Dehiscent** Splitting open at maturity to release the contents. *Cf.* indehiscent.
- Deltate** Triangular shape.
- Deltoid** Shaped like an equilateral triangle.
- Dendritic** Branching from a main stem or axis like the branches of a tree.
- Dentate** With sharp, rather coarse teeth perpendicular to the margin.
- Denticulate** Finely toothed.
- Diageotropic** The tendency of growing parts, such as roots, to grow at right angle to the line of gravity.
- Diadelphous** Having stamens in two bundles as in Papilionaceae flowers.
- Dichasium** A cymose inflorescence in which the branches are opposite and approximately equal. *Pl.* dichasia; *Adj.* dichasial.
- Dichotomous** divided into two parts.
- Dicotyledon** Angiosperm with two cotyledons.
- Didymous** Arranged or occurring in pairs as of anthers, having two lobes.
- Digitate** Having digits or fingerlike projections.
- Dikaryophyses** Or dendrophydia, irregularly, strongly branched terminal hyphae in the Hymenomycetes (class of Basidiomycetes) fungi.
- Dimorphic** Having or occurring in two forms, as of stamens of two different lengths or a plant having two kinds of leaves.
- Diocious** With male and female unisexual flowers on separate plants. *Cf.* monoecious.
- Diploid** A condition in which the chromosomes in the nucleus of a cell exist as pairs, one set being derived from the female parent and the other from the male.
- Diplobiontic Life Cycle** Life cycle that exhibits alternation of generations, which features of spore-producing multicellular sporophytes and gamete-producing multicellular gametophytes. Mitoses occur in both the diploid and haploid phases.
- Diplontic Life Cycle** Or gametic meiosis, wherein instead of immediately dividing meiotically to produce haploid cells, the zygote divides mitotically to produce a multicellular diploid individual or a group of more diploid cells.
- Diplochory** Seed dispersal involving two or more modes.
- Dipterocarpus** Trees of the family Dipterocarpaceae, with two-winged fruit found mainly in tropical lowland rainforest.
- Disc (Botany)** Refers to the usually disc-shaped receptacle of the flower head in Asteraceae; also the fleshy nectariferous organ usually between the stamens and ovary; also used for the enlarged style-end in Proteaceae.
- Disc Floret** The central, tubular 4 or 5 toothed or lobed floret on the disc of an inflorescence, as of flower head of Asteraceae.
- Disciform** Flat and rounded in shaped. *Cf.* discoid, radiate.
- Discoid** Resembling a disc; having a flat, circular form; disc-shaped. *Cf.* disciform, radiate.
- Discolorous** Having two colours, as of a leaf which has different colours on the two surfaces. *Cf.* concolorous.

- Disomic** Having one or more chromosomes present twice but without the entire genome doubled.
- Dispersal** Dissemination of seeds.
- Distal** Site of any structure farthest from the point of attachment. *Cf.* proximal.
- Distichous** Referring to two rows of upright leaves in the same plane.
- Dithecous** Having two thecae.
- Divaricate** Diverging at a wide angle.
- Domatium** A part of a plant (e.g. a leaf) that has been modified to provide protection for other organisms. *Pl.* domatia.
- Dormancy** A resting period in the life of a plant during which growth slows or appears to stop.
- Dorsal** Referring to the back surface.
- Dorsifixed** Attached to the back as of anthers.
- Drupaceous** Resembling a drupe.
- Drupe** A fleshy fruit with a single seed enclosed in a hard shell (endocarp) which is tissue embedded in succulent tissue (mesocarp) surrounded by a thin outer skin (epicarp). *Adj.* drupaceous.
- Drupelet** A small drupe.
- Ebracteate** Without bracts.
- Echinate** Bearing stiff, stout, bristly, prickly hairs.
- Edaphic** Refers to plant communities that are distinguished by soil conditions rather than by the climate.
- Eglandular** Without glands. *Cf.* glandular.
- Elaeoplasts** A type of leucoplast that is specialized for the storage of lipids in plants.
- Elaiosome** Fleshy lipid-rich structures that are attached to the seeds of many plant species.
- Ellipsoid** A 3-dimensional shape; elliptic in outline.
- Elliptic** Having a 2-dimensional shape of an ellipse or flattened circle.
- Elongate** Extended, stretched out.
- Emarginate** Refers to leaf with a broad, shallow notch at the apex. *Cf.* retuse.
- Embryo (Botany)** A minute rudimentary plant contained within a seed or an archegonium, composed of the embryonic axis (shoot end and root end).
- Endemic** Prevalent in or peculiar to a particular geographical locality or region.
- Endocarp** The hard innermost layer of the pericarp of many fruits.
- Endosperm** Tissue that surrounds and nourishes the embryo in the angiosperm seed. It contains starchy carbohydrates, proteins and small amounts of vitamins and minerals.
- Endospermous** Refers to seeds having an endosperm.
- Ensiform** Shaped like the blade of a sword, long and narrow with sharp edges and a pointed tip.
- Endotrophic** As of mycorrhiza obtaining nutrients from inside.
- Ensilage** The process of preserving green food for livestock in an undried condition in airtight conditions. Also called silaging.
- Entire** Having a smooth, continuous margin without any incisions or teeth as of a leaf.
- Entisols** Soils that do not show any profile development other than an A horizon.
- Ephemeral** Transitory, short lived.
- Epicalyx** A whorl of bracts, subtending and resembling a calyx.
- Epicarp** Outermost layer of the pericarp of a fruit.
- Epicormic** Attached to the corm.
- Epicotyl** The upper portion of the embryonic axis, above the cotyledons and below the first true leaves.
- Epigeal** Above ground with cotyledons raised above ground.
- Epiparasite** An organism parasitic on another that parasitizes a third.
- Epipetalous** Borne on the petals, as of stamens.
- Epiphyte** A plant growing on, but not parasitic on, another plant, deriving its moisture and nutrients from the air and rain, e.g. some Orchidaceae. *Adj.* epiphytic.
- Epithet** Name.
- Erect** Upright, vertical.
- Essential Oils** Volatile products obtained from a natural source; refers to volatile products obtained by steam or water distillation in a strict sense.
- Etiolation** To cause (a plant) to develop without chlorophyll by preventing exposure to sunlight.
- Eutrophic** Having waters rich in mineral and organic nutrients that promote a proliferation of plant life, especially algae, which reduces the dissolved oxygen content and often causes the extinction of other organisms.

- Excentric** Off the true centre.
- Excrescence** Abnormal outgrowth.
- Excurrent** Projecting beyond the tip, as the midrib of a leaf or bract.
- Exserted** Sticking out, protruding beyond some enclosing organ, as of stamens which project beyond the corolla or perianth.
- Exstipulate** Without stipules. *Cf.* stipulate.
- Extra-floral** Outside the flower.
- Extorse** Turned outwards or away from the axis as of anthers. *Cf.* introrse, latorse.
- Falcate** sickle shaped, crescent shaped.
- Fascicle** A cluster or bundle of stems, flowers, stamens. *Adj.* fasciculate.
- Fasciclude** Staminode bundles.
- Fastigiate** A tree in which the branches grow almost vertically.
- Ferrosols** Soils with an iron oxide content of greater than 5 %.
- Ferruginous** Rust coloured, reddish-brown.
- Fertile** Having functional sexual parts which are capable of fertilization and seed production. *Cf.* sterile.
- Filament** The stalk of a stamen supporting and subtending the anther.
- Filiform** Having the form of or resembling a thread or filament.
- Fimbriate** Fringed.
- Fixed Oils** Nonvolatile oils, triglycerides of fatty acids.
- Flaccid** Limp and weak.
- Flag Leaf** The uppermost leaf on the stem.
- Flaky** In the shape of flakes or scales.
- Flexuous** Zigzagging, sinuous, bending, as of a stem.
- Floccose** Covered with tufts of soft woolly hairs.
- Floral Tube** A flower tube usually formed by the basal fusion of the perianth and stamens.
- Floret** One of the small individual flowers of sunflower family or the reduced flower of the grasses, including the lemma and palea.
- Flower** The sexual reproductive organ of flowering plants, typically consisting of gynoecium, androecium and perianth or calyx and/or corolla and the axis bearing these parts.
- Fluted** As of a trunk with grooves and folds.
- Fodder** Plant material, fresh or dried fed to animals.
- Foliaceous** Leaf like.
- Foliage** Leaves of the plant.
- Foliar** Pertaining to a leaf.
- Foliate** Pertaining to leaflets, used with a number prefix to denote the number of leaflets.
- Foliose** Leaf like.
- Follicle (Botany)** A dry fruit, derived from a single carpel and dehiscing along one suture.
- Forb** Any herb that is not grass or grass like.
- Foveolate** Surface pitted with shallow depressions.
- Free Central Placentation** The arrangement of ovules on a central column that is not connected to the ovary wall by partitions, as in the ovaries of the carnation and primrose.
- Fronde** The leaf of a fern or cycad.
- Fruit** Ripened ovary with adnate parts.
- Frutescent** Shrubby.
- Fugacious** Shedding off early.
- Fulvous** Yellow, tawny.
- Funiculus (Botany)** Short stalk which attaches the ovule to the ovary wall.
- Fuscescent** Dusky.
- Fusiform** A 3-dimensional shape; spindle shaped, i.e. broad in the centre and tapering at both ends thick, but tapering at both ends.
- Gall Flower** Short-styled flowers that do not develop into a fruit but are adapted for the development of a specific wasp within the fruit, e.g. in the fig.
- Gamete** A reproductive cell that fuses with another gamete to form a zygote. Gametes are haploid, (they contain half the normal (diploid) number of chromosomes); thus, when two fuse, the diploid number is restored.
- Gametophyte** The gamete-producing phase in a plant characterized by alternation of generations.
- Gamosepalous** With sepals united or partially united.
- Genome** Complete set of genetic material of an organism.
- Geniculate** Bent like a knee; refers to awns and filaments.
- Geocarpic** Where the fruit are pushed into the soil by the gynophore and mature.

- Geophyte** A plant that stores food in an underground storage organ, e.g. a tuber, bulb or rhizome and has subterranean buds which form aerial growth.
- Geotextile** Are permeable fabrics which, when used in association with soil, have the ability to separate, filter, reinforce, protect or drain.
- Germ** Of cereal is the embryo of the seed or kernel. It contains vitamins B and E, folic acid, some protein, minerals and polyunsaturated fats.
- Glabrescent** Becoming glabrous.
- Glabrous** Smooth, hairless without pubescence.
- Gland** A secretory organ, e.g. a nectary, extrafloral nectary or a gland tipped, hair like or wart like organ. *Adj.* glandular; *Cf.* eglandular.
- Glaucous** Pale blue-green in colour, covered with a whitish bloom that rubs off readily.
- Gley Soils** A hydric soil which exhibits a greenish-blue-grey soil colour due to wetland conditions.
- Globose** Spherical in shape.
- Globular** A three-dimensional shape; spherical or orbicular; circular in outline.
- Glochids** Tiny, finely barbed hair-like spines found on the areoles of some cacti and other plants.
- Glochidiate** Having glochids.
- Glochidote** Plant having glochids.
- Glume** One of the two small, sterile bracts at the base of the grass spikelet, called the lower and upper glumes, due to their position on the rachilla. Also used in Apiaceae and Cyperaceae for the very small bracts on the spikelet in which each flower is subtended by one floral glume. *Adj.* glumaceous.
- Grits** Consist of coarsely ground corn or sometimes alkali-treated corn.
- Groats** Hulled, whole grains of various cereals, such as oats, wheat, barley or buckwheat, it includes the cereal germ, fibre-rich bran portion and endosperm of the grain.
- Guttation** The appearance of drops of xylem sap on the tips or edges of leaves of some vascular plants, such as grasses and bamboos.
- Guttule** Small droplet.
- Gymnosperm** A group of spermatophyte seed-bearing plants with ovules on scales, which are usually arranged in cone-like structures and not borne in an ovary. *Cf.* angiosperm.
- Gynoeceum** The female organ of a flower; a collective term for the pistil, carpel or carpels.
- Gynomonoecious** Having female flowers and bisexual flowers on the same plant. *Cf.* andromonoecious.
- Gynophore** Stalk that bears the pistil/carpel.
- Habit** The general growth form of a plant, comprising its size, shape, texture and stem orientation; the locality in which the plant grows.
- Halophyte** A plant adapted to living in highly saline habitats. Also a plant that accumulates high concentrations of salt in its tissues. *Adj.* halophytic.
- Hapaxanthic** Refers to palms which flowers only once and then dies. *Cf.* pleonanthic.
- Haploid** Condition where nucleus or cell has a single set of unpaired chromosomes, the haploid number is designated as *n*.
- Haplontic Life Cycle** Or zygotic meiosis wherein meiosis of a zygote, immediately after karyogamy, produces haploid cells which produces more or larger haploid cells ending its diploid phase.
- Hastate** Having the shape of an arrowhead but with the basal lobes pointing outwards at right angles as of a leaf.
- Hastula** A piece of plant material at the junction of the petiole and the leaf blade; the hastula can be found on the top of the leaf, adaxial or the bottom, abaxial or both sides.
- Heartwood** Wood from the inner portion of a tree.
- Heliophilous** Sun loving, tolerates high level of sunlight.
- Heliotropic** Growing towards sunlight.
- Herb** A plant which is nonwoody or woody at the base only, the above ground stems usually being ephemeral. *Adj.* herbaceous.
- Herbaceous** Resembling an herb, having a habit of an herb.
- Hermaphrodite** Bisexual, bearing flowers with both androeceum and gynoeceum in the same flower. *Adj.* hermaphroditic.
- Heterocyst** A differentiated cyanobacterial cell that carries out nitrogen fixation.
- Heterogamous** Bearing separate male and female flowers, or bisexual and female

- flowers, or florets in an inflorescence or flower head, e.g. some Asteraceae in which the ray florets may be neuter or unisexual and the disc florets may be bisexual. *Cf.* homogamous.
- Heteromorphous** Having two or more distinct forms. *Cf.* homomorphous.
- Heterophyllous** Having leaves of different form.
- Heterosporous** Producing spores of 2 sizes, the larger giving rise to megagametophytes (female), the smaller giving rise to microgametophytes (male). Refer to the ferns and fern allies. *Cf.* homosporous.
- Heterostylous** Having styles of two different lengths or forms.
- Heterostyly** The condition in which flowers on polymorphous plants have styles of different lengths, thereby facilitating cross-pollination.
- Hilar** Of or relating to a hilum.
- Hilum** The scar on a seed, indicating the point of attachment to the funiculus.
- Hirsute** Bearing long coarse hairs.
- Hispid** Bearing stiff, short, rough hairs or bristles.
- Hispidulous** Minutely hispid.
- Histosol** Soil comprising primarily of organic materials, having 40 cm or more of organic soil material in the upper 80 cm.
- Hoary** Covered with a greyish layer of very short, closely interwoven hairs.
- Holdfast** An organ or structure of attachment, especially the basal, root-like formation by which certain seaweeds or other algae are attached to a substrate.
- Holocarpic** Having the entire thallus developed into a fruiting body or sporangium.
- Homochromous** Having all the florets of the same colour in the same flower head. *Cf.* heterochromous.
- Homogamous** Bearing flowers or florets that do not differ sexually. *Cf.* heterogamous.
- Homogenous Endosperm** Endosperm with even surface that lacks invaginations or infoldings of the surrounding tissue.
- Hormogonium** A part of a filament of a cyanobacterium that detaches and grows by cell division into a new filament. *Pl.* hormogonia.
- Homomorphous** Uniform, with only one form. *Cf.* heteromorphous.
- Homosporous** Producing one kind of spores. Refer to the ferns and fern allies. *Cf.* heterosporous.
- Hurd Fibre** Long pith fibre of the stem.
- Hyaline** Colourless, almost transparent.
- Hybrid** The first generation progeny of the sexual union of plants belonging to different taxa.
- Hybridisation** The crossing of individuals from different species or taxa.
- Hydathode** A type of secretory tissue in leaves, usually of Angiosperms, that secretes water through pores in the epidermis or margin of the leaf.
- Hydrophilous** Water loving; requiring water in order to be fertilized, referring to many aquatic plants.
- Hygrochastic** Applied to plants in which the opening of the fruits is caused by the absorption of water.
- Hygrophilous** Living in water or moist places.
- Hymenial cystidia** The cells of the hymenium develop into basidia or asci, while in others some cells develop into sterile cells called cystidia.
- Hymenium** Spore-bearing layer of cells in certain fungi containing asci (Ascomycetes) or basidia (Basidiomycetes).
- Hypanthium** Cuplike receptacles of some dicotyledonous flowers formed by the fusion of the calyx, corolla and androecium that surround the ovary which bears the sepals, petals and stamens.
- Hypha** Is a long, branching filamentous cell of a fungus and also of unrelated Actinobacteria. *Pl.* hyphae.
- Hypocotyl** The portion of the stem below the cotyledons.
- Hypodermis** The cell layer beneath the epidermis of the pericarp.
- Hypogeal** Below ground as of germination of seed.
- Hysteresis** Refers to systems that may exhibit path dependence.
- Imbricate** Closely packed and overlapping. *Cf.* valvate.
- Imparipinnate** Pinnately compound with a single terminal leaflet and hence with an odd number of leaflets. *Cf.* paripinnate.
- Inceptisols** Old soils that have no accumulation of clays, iron, aluminium or organic matter.

- Incised** Cut jaggedly with very deep teeth.
- Included** Referring to stamens which do not project beyond the corolla or to valves which do not extend beyond the rim of a capsular fruit. *Cf.* exserted.
- Incurved** Curved inwards; curved towards the base or apex.
- Indefinite** Numerous and variable in number.
- Indehiscent** Not opening or splitting to release the contents at maturity as of fruit. *Cf.* dehiscent.
- Indumentum** Covering of fine hairs or bristles commonly found on external parts of plants.
- Indurate** To become hard, often the hardening developed only at maturity.
- Indusium** An enclosing membrane, covering the sorus of a fern. Also used for the modified style end or pollen-cup of some Goodeniaceae (including Brunoniaceae). *Adj.* indusiate.
- Inferior** Said of an ovary or fruit that has sepals, petals and stamens above the ovary. *Cf.* superior.
- Inflated** Enlarged and hollow except in the case of a fruit which may contain a seed. *Cf.* swollen.
- Inflexed** Bent or curved inwards or downwards, as petals or sepals.
- Inflorescence** A flower cluster or the arrangement of flowers in relation to the axis and to each other on a plant.
- Infrafoliar** Located below the leaves.
- Infraspecific** Referring to any taxon below the species rank.
- Infructescence** The fruiting stage of an inflorescence.
- Inrolled** Curved inwards.
- Integuments** Two distinct tissue layers that surround the nucellus of the ovule, forming the testa or seed coat when mature.
- Intercalary** Of growth, between the apex and the base; of cells, spores, etc., between two cells.
- Interfoliar** Inter leaf.
- Internode** Portion of the stem, culm, branch or rhizome between two nodes or points of attachment of the leaves.
- Interpetiolar** As of stipules positioned between petioles of opposite leaves.
- Intrastaminal** Within the stamens.
- Intricate** Entangled, complex.
- Introduced** Not indigenous; not native to the area in which it now occurs.
- Introrse** Turned inwards or towards the axis or pistil as of anthers. *Cf.* extrorse, latrorse.
- Involucre** A whorl of bracts or leaves that surround one to many flowers or an entire inflorescence.
- Involute** Having the margins rolled inwards, referring to a leaf or other flat organ.
- Jugate** Of a pinnate leaf; having leaflets in pairs.
- Juvenile** Young or immature, used here for leaves formed on a young plant which are different in morphology from those formed on an older plant.
- Keel** A longitudinal ridge, at the back of the leaf. Also the two lower fused petals of a 'pea' flower in the Papilionaceae, which form a boatlike structure around the stamens and styles. Also called carina. *Adj.* keeled. *Cf.* standard, wing.
- Labellum** The modified lowest of the three petals forming the corolla of an orchid, usually larger than the other two petals, and often spurred.
- Lacerate** Irregularly cleft.
- Laciniate** Fringed; having a fringe of slender, narrow, pointed lobes cut into narrow lobes.
- Lamella** A gill-shaped structure: fine sheets of material held adjacent to one another.
- Lamina** The blade of the leaf or frond.
- Lanate** Woolly, covered with long hairs which are loosely curled together like wool.
- Lanceolate** Lance shaped in outline, tapering from a broad base to the apex.
- Landrace** Plants adapted to the natural environment in which they grow, developing naturally with minimal assistance or guidance from humans and usually possess more diverse phenotypes and genotypes. They have not been improved by formal breeding programs.
- Laterite** Reddish-coloured soils rich in iron oxide, formed by weathering of rocks under oxidizing and leaching conditions, commonly found in tropical and subtropical regions. *Adj.* lateritic.
- Latex** A milky, clear or sometimes coloured sap of diverse composition exuded by some plants.
- Latrorse** Turned sideways, i.e. not towards or away from the axis as of anthers dehiscing longitudinally on the side. *Cf.* extrorse, introrse.
- Lax** Loose or limp, not densely arranged or crowded.

- Leaflet** One of the ultimate segments of a compound leaf.
- Lectotype** A specimen chosen after the original description to be the type.
- Lemma** The lower of two bracts (scales) of a grass floret, usually enclosing the palea, lodicules, stamens and ovary.
- Lenticel** Is a lens-shaped opening that allows gases to be exchanged between air and the inner tissues of a plant, commonly found on young bark, or the surface of the fruit.
- Lenticellate** Dotted with lenticels.
- Lenticular** Shaped like a biconvex lens. *Cf.* lentiform.
- Lentiform** Shaped like a biconvex lens. *Cf.* lenticular.
- Leptomorph** Temperate, running bamboo rhizome; usually thinner than the culms they support and the internodes are long and hollow.
- Liane** A woody climbing or twining plant.
- Ligneous** Woody.
- Lignotuber** A woody, usually underground, tuberous rootstock often giving rise to numerous aerial stems.
- Ligulate** Small and tongue shaped or with a little tongue-shaped appendage or ligule, star shaped as of florets of Asteraceae.
- Ligule** A strap-shaped corolla in the flowers of Asteraceae; also a thin membranous outgrowth from the inner junction of the grass leaf sheath and blade. *Cf.* ligulate.
- Limb** The expanded portion of the calyx tube or the corolla tube or the large branch of a tree.
- Linear** A 2-dimensional shape, narrow with nearly parallel sides.
- Linguiform** Tongue shaped. *Cf.* ligulate.
- Lipotubuloids** Are cytoplasmic domains containing aggregates of lipid bodies surrounded by a network of microtubules, which join one lipid body with the others.
- Lithosol** A kind of shallow soils lacking well-defined horizons and composed of imperfectly weathered fragments of rock.
- Littoral** Of or on a shore, especially seashore.
- Loam** A type of soil made up of sand, silt and clay in relative concentration of 40 %, 40 %, 20 % respectively.
- Lobed** Divided but not to the base.
- Loculicidal** Opening into the cells, when a ripe capsule splits along the back.
- Locus** Cavity or chamber of an ovary. *Pl.* loculi.
- Lodicules** Two small structures below the ovary which, at flowering, swell up and force open the enclosing bracts, exposing the stamens and carpel.
- Lorate** Strap shaped with obtuse tip.
- Lyrate** Pinnately lobed, with a large terminal lobe and smaller laterals ones which become progressively smaller towards the base.
- Macronutrients** Chemical elements which are needed in large quantities for growth and development by plants and include nitrogen, phosphorus, potassium and magnesium.
- Maculate** Spotted.
- Mallee** A growth habit in which several to many woody stems arise separately from a lignotuber; usually applied to certain low-growing species of *Eucalyptus*.
- Mangrove** A distinctive vegetation type of trees and shrubs with modified roots, often viviparous, occupying the saline coastal habitats that are subject to periodic tidal inundation.
- Marcrescent** Withering or to decay without falling off.
- Margin** The edge of the leaf blade.
- Medulla** The pith in the stems or roots of certain plants, or the central portion of a thallus in certain lichens.
- Megasporangium** The sporangium containing megaspores in fern and fern allies. *Cf.* microsporangium.
- Megaspore** The large spore which may develop into the female gametophyte in heterosporous ferns and fern allies. *Cf.* microspore.
- Megasporophyll** A leaflike structure that bears megasporangia.
- Megastrobilus** Female cone, seed cone or ovulate cone, contains ovules within which, when fertilized by pollen, become seeds. The female cone structure varies more markedly between the different conifer families.
- Meiosis** The process of cell division that results in the formation of haploid cells from diploid cells to produce gametes.

- Mericarp** A 1-seeded portion of an initially syncarpous fruit (schizocarp) which splits apart at maturity. *Cf.* coccus.
- Meristem** The region of active cell division in plants, from which permanent tissue is derived. *Adj.* meristematic.
- Merous** Used with a number prefix to denote the basic number of the 3 outer floral whorls, e.g. a 5-merous flower may have 5 sepals, 10 petals and 15 stamens.
- Mesic** Moderately wet.
- Mesocarp** The middle layer of the fruit wall derived from the middle layer of the carpel wall. *Cf.* endocarp, exocarp, pericarp.
- Mesophytes** Terrestrial plants which are adapted to neither a particularly dry nor particularly wet environment.
- Micropyle** The small opening in a plant ovule through which the pollen tube passes in order to effect fertilization.
- Microsporangium** The sporangium containing microspores in pteridophytes. *Cf.* megasporangium.
- Microspore** A small spore which gives rise to the male gametophyte in heterosporous pteridophytes. Also for a pollen grain. *Cf.* megaspore.
- Midvein** The main vascular supply of a simple leaf blade or lamina. Also called midrib.
- Mitosis** Is a process of cell division which results in the production of two daughter cells from a single parent cell.
- Mollisols** Soils with deep, high organic matter, nutrient-enriched surface soil (A horizon), typically between 60 and 80 cm thick.
- Monadelphous** Applied to stamens united by their filaments into a single bundle.
- Monocarpic** Refers to plants that flower, set seeds and then die.
- Monochasial** A cyme having a single flower on each axis.
- Monocotyledon** Angiosperm having one cotyledon.
- Monoecious** Having both male and female unisexual flowers on the same individual plant. *Cf.* dioecious.
- Monoembryonic Seed** The seed contains only one embryo, a true sexual (zygotic) embryo, polyembryonic seed.
- Monolete** A spore that has a simple linear scar.
- Monopodial** With a main terminal growing point producing many lateral branches progressively. *Cf.* sympodial.
- Monotypic** Of a genus with one species or a family with one genus, in general, applied to any taxon with only one immediately subordinate taxon.
- Montane** Refers to highland areas located below the subalpine zone.
- Mucilage** A soft, moist, viscous, sticky secretion. *Adj.* mucilaginous.
- Mucous** Botany, slimy.
- Mucro** A sharp, pointed part or organ, especially a sharp terminal point, as of a leaf.
- Mucronate** Ending with a short, sharp tip or mucro, resembling a spine. *Cf.* cuspidate, muticous.
- Mucronulate** With a very small mucro; a diminutive of mucronate.
- Mulch** Protective cover of plant (organic) or non-plant material placed over the soil, primarily to modify and improve the effects of the local microclimate and to control weeds.
- Multiple Fruit** A fruit that is formed from a cluster of flowers.
- Muricate** Covered with numerous short hard outgrowths. *Cf.* papillose.
- Muriculate** With numerous minute hard outgrowths; a diminutive of muricate.
- Muticous** Blunt, lacking a sharp point. *Cf.* mucronate.
- MYB Proteins** Are a superfamily of transcription factors that play regulatory roles in developmental processes and defense responses in plants.
- Mycorrhiza** The mutualistic symbiosis (nonpathogenic association) between soil-borne fungi with the roots of higher plants.
- Mycorrhiza (Vesicular Arbuscular)** Endomycorrhiza living in the roots of higher plants producing inter-and intracellular fungal growth in root cortex and forming specific fungal structures, referred to as vesicles and arbuscles. *Abbrev.* VAM.
- Myrmecochory** Seed dispersal by ants.
- Native** A plant indigenous to the locality or region.
- Naviculate** Boat shaped.
- Necrotic** Applied to dead tissue.
- Nectariferous** Having one or more nectaries.

- Nectary** A nectar secretory gland; commonly in a flower, sometimes on leaves, fronds or stems.
- Nervation** Venation, a pattern of veins or nerves as of leaf.
- Nixtamalization** Refers to a process for the preparation of maize (corn), or other grain, in which the grains are soaked and cooked in an alkaline solution, usually limewater, and hulled.
- Node** The joint between segments of a culm, stem, branch or rhizome; the point of the stem that gives rise to the leaf and bud.
- Nodule** A small knoblike outgrowth, as those found on the roots of many leguminous, that contains *Rhizobium* bacteria which fix nitrogen in the soil.
- Nom. ambig.** Nomen ambiguum (Latin). Ambiguous name used in different senses which has become a long-persistent source of error.
- Nom. cons.** Nomen consensu (Latin). Name conserved in International Code of Botanical Nomenclature.
- Nom. dub.** Nomen dubium (Latin). An invalid proposed taxonomic name because it is not accompanied by a definition or description of the taxon to which it applies.
- Nom. illeg.** Nomen illegitimum (Latin). Illegitimate taxon deemed as superfluous at its time of publication either because the taxon to which it was applied already has a name, or because the name has already been applied to another plant.
- Nom. invalid.** Nomen invalidum (Latin). Invalid name according to International Code of Botanical Nomenclature.
- Nom. nud.** Nomen nudum (Latin). The name of a taxon which has never been validated by a description.
- Nom. rej.** Nomen rejiciendum (Latin). Name rejected in International Code of Botanical Nomenclature.
- Notho (Subsp. or Var.)** Prefix to the rank of a hybrid taxon below the rank of species.
- Nucellus** Central portion of an ovule in which the embryo sac develops.
- Nucellar Embryony** A form of seed reproduction in which the nucellar tissue which surrounds the embryo sac can produce additional embryos (polyembryony) which are genetically identical to the parent plant. This is found in many citrus species and in mango.
- Nut** A dry indehiscent 1-celled fruit with a hard pericarp.
- Nutlet** A small, 1-seeded, indehiscent lobe of a divided fruit.
- Ob-** Prefix meaning inversely or opposite to.
- Obconic** A 3-dimensional shape; inversely conic; cone shaped, conic with the vertex pointing downward.
- Obcordate** Inversely cordate, broad and notched at the tip; heart shaped but attached at the pointed end.
- Obdeltate** Inversely deltate; deltate with the broadest part at the apex.
- Ob lanceolate** Inversely lanceolate, lance shaped but broadest above the middle and tapering towards the base as of leaf.
- Oblate** Having the shape of a spheroid with the equatorial diameter greater than the polar diameter; being flattened at the poles.
- Oblong** Longer than broad with sides nearly parallel to each other.
- Obovate** Inversely ovate, broadest above the middle.
- Obpyramidal** Resembling a 4-sided pyramid attached at the apex with the square base facing away from the attachment.
- Obpyriform** Inversely pyriform, resembling a pear which is attached at the narrower end. *Cf.* pyriform.
- Obspathulate** Inversely spathulate; resembling a spoon but attached at the broadest end. *Cf.* spathulate.
- Obtriangular** Inversely triangular; triangular but attached at the apex. *Cf.* triangular.
- Obtrullate** Inversely trullate; resembling a trowel blade with the broadest axis above the middle. *Cf.* trullate.
- Obtuse** With a blunt or rounded tip, the converging edges separated by an angle greater than 90°.
- Ochraceous** A dull yellow colour.
- Ocreate** Having a tube-like covering around some stems, formed of the united stipules; sheathed.
- oid** Suffix denoting a 3-dimensional shape, e.g. spheroid.

Oleaginous Oily.

Oligotrophic Lacking in plant nutrients and having a large amount of dissolved oxygen throughout.

Operculum A lid or cover that becomes detached at maturity by abscission, e.g. in *Eucalyptus*, also a cap or lid covering the bud and formed by fusion or cohesion of sepals and/or petals. *Adj.* operculate.

Opposite Describing leaves or other organs which are borne at the same level but on opposite sides of the stem. *Cf.* alternate.

Orbicular Of circular outline, disc like.

Order A taxonomic rank between class and family used in the classification of organisms, i.e. a group of families believed to be closely related.

Orifice An opening or aperture.

Organosols Soils not regularly inundated by marine waters and containing a specific thickness of organic materials within the upper part of the profile.

Orth. Var. Orthographic variant, i.e. an incorrect alternate spelling of a name.

Ovary The female part of the pistil of a flower which contains the ovules (immature seeds).

Ovate Egg shaped, usually with reference to two dimensions.

Ovoid Egg shaped, usually with reference to three dimensions.

Ovule The young, immature seed in the ovary which becomes a seed after fertilization. *Adj.* ovular.

Ovulode A sterile reduced ovule borne on the placenta, commonly occurring in Myrtaceae.

Oxisols Refer to ferralsols.

Pachymorphic Describes the short, thick, rhizomes of clumping bamboos with short, thick and solid internode (except the bud-bearing internodes, which are more elongated). *Cf.* sympodial.

Palate (Botany) A raised appendage on the lower lip of a corolla which partially or completely closes the throat.

Palea The upper of the two membranous bracts of a grass floret, usually enclosing the lodicules, stamens and ovary. *Pl.* paleae; *Adj.* paleal; *Cf.* lemma.

Paleate Having glumes.

Palm Heart Refers to soft, tender inner core and growing bud of certain palm trees which are eaten as vegetables. Also called heart of palm, palmito, burglar's thigh, chonta or swamp cabbage.

Palmate Describing a leaf which is divided into several lobes or leaflets which arise from the same point. *Adj.* palmately.

Palmito See Palm Heart.

Palustrial Paludal, swampy, marshy.

Palustrine Marshy, swampy.

Palustrine Herb Vegetation that is rooted below water but grows above the surface in wetland system.

Panduriform Fiddle shaped, usually with reference to two dimensions.

Panicle A compound, indeterminate, racemose inflorescence in which the main axis bears lateral racemes or spikes. *Adj.* paniculate.

Pantropical Distributed throughout the tropics.

Papilionaceous Butterfly like; said of the pea flower or flowers of Papilionaceae; flowers which are zygomorphic with imbricate petals, one broad upper one, two narrower lateral ones and two narrower lower ones.

Papilla A small, superficial protuberance on the surface of an organ being an outgrowth of one epidermal cell. *Pl.* papillae; *Adj.* papillose.

Papillate Having papillae.

Papillose Covered with papillae.

Pappus A tuft (or ring) of hairs, bristles or scales borne above the ovary and outside the corolla as in Asteraceae often persisting as a tuft of hairs on a fruit. *Adj.* pappose.

Papyraceous Resembling parchment of paper.

Parenchyma Undifferentiated plant tissue composed of more or less uniform cells.

Parietal Describes the attachment of ovules to the outer walls of the ovaries.

Paripinnate Pinnate with an even number of leaflets and without a terminal leaflet. *Cf.* imparipinnate.

-partite Divided almost to the base into segments, the number of segments written as a prefix.

Patelliform Shaped like a limpet shell; cap shaped and without whorls.

Patent Diverging from the axis almost at right angles.

- Peat** Is an accumulation of partially decayed vegetation matter.
- Pectin** A group of water-soluble colloidal carbohydrates of high molecular weight found in certain ripe fruits.
- Pectinate** Pinnatifid with narrow segments resembling the teeth of a comb.
- Pedicel** The stalk of the flower or stalk of a spikelet in Poaceae. *Adj.* pedicellate.
- Pedicellate** Having pedicel.
- Peduncle** A stalk supporting an inflorescence. *Adj.* pedunculate
- Pellucid** Allowing the passage of light; transparent or translucent.
- Pellucid Dotted** Copiously dotted with immersed, pellucid, resinous glands.
- Peltate** With the petiole attached to the lower surface of the leaf blade.
- Pendant** Hanging down.
- Pendulous** Drooping, as of ovules.
- Penniveined or Penni-nerved** Pinnately veined.
- Pentamerous** In five parts.
- Perennial** A plant that completes its life cycle or lives for more than 2 years. *Cf.* annual, biennial.
- Perfoliate** A leaf with the basal lobes united around, and apparently pierced by, the stem.
- Pergamentaceous** Parchment like.
- Perianth** The two outer floral whorls of the Angiosperm flower; commonly used when the calyx and the corolla are not readily distinguishable (as in monocotyledons).
- Pericarp (Botany)** The wall of a ripened ovary; fruit wall composed of the exocarp, mesocarp and endocarp.
- Persistent** Remaining attached; not falling off. *Cf.* caduceus.
- Petal** Free segment of the corolla. *Adj.* petaline; *Cf.* lobe.
- Petiole** Relating to the petiole.
- Petiolate** Having petiole.
- Petiole** Leafstalk. *Adj.* petiolate.
- Petiolulate** Supported by its own petiolule.
- Petiolule** The stalk of a leaflet in a compound leaf. *Adj.* petiolulate.
- pH** Is a measure of the acidity or basicity of a solution. It is defined as the cologarithm of the activity of dissolved hydrogen ions (H⁺).
- Phenology** The study of periodic plant life cycle events as influenced by seasonal and interannual variations in climate.
- Phyllary** A bract of the involucre of a composite plant, term for one of the scale-like bracts beneath the flower head in Asteraceae.
- Phylloclade** A flattened, photosynthetic branch or stem that resembles or performs the function of a leaf, with the true leaves represented by scales.
- Phyllode** A petiole that function as a leaf. *Adj.* phyllodineous; *Cf.* cladode.
- Phyllopodia** Refers to the reduced, scale-like leaves found on the outermost portion of the corm where they seem to persist longer than typical sporophylls as in the fern *Isoetes*.
- Phytoremediation** Describes the treatment of environmental problems (bioremediation) through the use of plants which mitigate the environmental problem without the need to excavate the contaminant material and dispose of it elsewhere.
- Pileus (Botany)** Cap of mushroom.
- Piliferous (Botany)** Bearing or producing hairs, as of an organ with the apex having long, hair-like extensions.
- Pilose** Covered with fine soft hairs.
- Pinna** A primary division of the blade of a compound leaf or frond. *Pl.* pinnae.
- Pinnate** Bearing leaflets on each side of a central axis of a compound leaf; divided into pinnae.
- Pinnatifid, Pinnatilobed** A pinnate leaf parted approximately halfway to midrib; when divided to almost to the midrib described as deeply pinnatifid or pinnatisect.
- Pinnatisect** Lobed or divided almost to the midrib.
- Pinnule** A leaflet of a bipinnate compound leaf.
- Pistil** Female part of the flower comprising the ovary, style and stigma.
- Pistillate** Having one or more pistils; having pistils but no stamens.
- Placenta** The region within the ovary to which ovules are attached. *Pl.* placentae.
- Placentation** The arrangement of the placentae and ovules in the ovary.
- Plano-** A prefix meaning level or flat.
- Pleonanthic** Refer to palms in which the stem does not die after flowering.

- Plicate** Folded like a fan.
- Plumose** Feather like, with fine hairs arising laterally from a central axis; feathery.
- Pneumatophore** Modified root which allows gaseous exchange in mud-dwelling shrubs, e.g. mangroves.
- Pod** A dry 1 to many-seeded dehiscent fruit, as applied to the fruit of Fabaceae, i.e. Caesalpinaceae, Mimosaceae and Papilionaceae.
- Podzol, Podsollic Soil** Any of a group of acidic, zonal soils having a leached, light-coloured, grey and ashy appearance. Also called spodosol.
- Pollen Cone** Male cone or microstrobilus or pollen cone is structurally similar across all conifers, extending out from a central axis are microsporophylls (modified leaves). Under each microsporophyll is one or several microsporangia (pollen sacs).
- Pollinia** The paired, waxy pollen masses of flowers of orchids and milkweeds.
- Polyandrous (Botany)** Having an indefinite number of stamens.
- Polyembryonic Seed** Seeds contain many embryos, most of which are asexual (nucellar) in origin and genetically identical to the maternal parent.
- Polygamous** With unisexual and bisexual flowers on the same or on different individuals of the same species.
- Polymorphic** With different morphological variants.
- Polypetalous (Botany)** Having a corolla composed of distinct, separable petals.
- Pome** A fleshy fruit where the succulent tissues are developed from the receptacle.
- Pore** A tiny opening.
- Premorse** Abruptly truncated, as though bitten or broken off as of a leaf.
- Procumbent** Trailing or spreading along the ground but not rooting at the nodes, referring to stems. *Cf.* ascending, decumbent, erect.
- Pro Hyb.** Latin, as a hybrid.
- Pro Parte** Latin, in part.
- Pro Parte Majore** Latin, for the greater part.
- Pro Parte Minore** Latin, for a small part.
- Pro Sp.** Latin, as a species.
- Pro Subsp.** Latin, as a subspecies.
- Pro Syn.** Latin, as a synonym.
- Prophyll** A plant structure that resembles a leaf.
- Prostrate** Lying flat on the ground.
- Protandrous** Relating to a flower in which the anthers release their pollen before the stigma of the same flower becomes receptive.
- Proximal** End of any structure closest to the point of attachment. *Cf.* distal.
- Pruinose** Having a thick, waxy, powdery coating or bloom.
- Pseudocarp** A false fruit, largely made up of tissue that is not derived from the ovary but from floral parts such as the receptacle and calyx.
- Pseudostem** The false, herbaceous stem of a banana plant composed of overlapping leaf bases.
- Pteridophyte** A vascular plant which reproduces by spores; the ferns and fern allies.
- Puberulent** Covered with minute hairs or very fine down; finely pubescent.
- Puberulous** Covered with a minute down.
- Pubescent** Covered with short, soft hairs.
- Pulvinate** Having a swelling, pulvinus at the base as a leafstalk.
- Pulvinus** Swelling at the base of leafstalk.
- Pulviniform** Swelling or bulging.
- Punctate** Marked with translucent dots or glands.
- Punctiform** Marked by or composed of points or dots.
- Punctulate** Marked with minute dots; a diminutive of punctate.
- Purpurascent** Purple or becoming purple.
- Pusticulate** Characterized by small pustules.
- Pyrene** The stone or pit of a drupe, consisting of the hardened endocarp and seed.
- Pyriform** Pear shaped, a 3-dimensional shape; attached at the broader end. *Cf.* obpyriform.
- Pyxidium** Seed capsule having a circular lid (operculum) which falls off to release the seed.
- Raceme** An indeterminate inflorescence with a simple, elongated axis and pedicellate flowers, youngest at the top. *Adj.* racemose.
- Rachilla** The main axis of a grass spikelet.
- Rachis** The main axis of the spike or other inflorescence of grasses or a compound leaf.
- Radiate** Arranged around a common centre; as of an inflorescence of Asteraceae with marginal, female or neuter, ligulate ray-florets and central, perfect or functionally male, tubular, disc florets. *Cf.* disciform, discoid.

- Radical** Arising from the root or its crown or the part of a plant embryo that develops into a root.
- Ray** The marginal portion of the inflorescence of Asteraceae and Apiaceae when distinct from the disc. Also, the spreading branches of a compound umbel.
- Receptacle** The region at the end of a pedicel or on an axis which bears one or more flowers. *Adj.* receptacular.
- Recurved** Curved downwards or backwards.
- Reflexed** Bent or turned downward.
- Regosol** Soil that is young and undeveloped, characterized by medium to fine-textured unconsolidated parent material that maybe alluvial in origin and lacks a significant horizon layer formation.
- Reniform** Kidney shaped in outline.
- Repend** With slightly undulate margin.
- Replicate** Folded back, as in some corolla lobes.
- Resinous** Producing sticky resin.
- Resupinate** Twisted through 180°.
- Reticulate** Having the appearance of a network.
- Retorse** Bent or directed downwards or backwards. *Cf.* antrorse.
- Retuse** With a very blunt and slightly notched apex. *Cf.* emarginated.
- Revolute** With the margins inrolled on the lower (abaxial) surface.
- Rhizine** A root-like filament or hair growing from the stems of mosses or on lichens.
- Rhizoid** Root-like filaments in a moss, fern, fungus, etc. that attach the plant to the substratum.
- Rhizome** A prostrate or underground stem consisting of a series of nodes and internodes with adventitious roots and which generally grows horizontally.
- Rhizophore** A stilt-like outgrowth of the stem which branches into roots on contact with the substrate.
- Rhombic** Shaped like a rhombus.
- Rhomboid** Shaped like a rhombus.
- Rib** A distinct vein or linear marking, often raised as a linear ridge.
- Riparian** Along the river margins, interface between land and a stream.
- Rosette** A tuft of leaves or other organs arranged spirally like petals in a rose, ranging in form from a hemispherical tuft to a flat whorl. *Adj.* rosetted, rosulate.
- Rostrate** Beaked; the apex tapered into a slender, usually obtuse point.
- Rostrum** A beak-like extension.
- Rosulate** Having a rosette.
- Rotate** Wheel shaped; refers to a corolla with a very short tube and a broad upper part which is flared at right angles to the tube. *Cf.* salverform.
- Rotundate** Rounded, especially at the end or ends.
- Rugae** Refers to a series of ridges produced by folding of the wall of an organ.
- Rugose** Deeply wrinkled.
- Rugulose** Finely wrinkled.
- Ruminate** Animal, chew repeatedly over an extended period.
- Ruminate Endosperm** Uneven endosperm surface that is often highly enlarged by ingrowths or infoldings of the surrounding tissue. *Cf.* homogenous endosperm.
- Rz Value** Is a numerical reference to the mesh/emulsion equalization on the screen.
- Saccate** Pouched.
- Sagittate** Shaped like an arrow head.
- Saline Soils** Soils that contain excessive levels of salts that reduce plant growth and vigour by altering water uptake and causing ion-specific toxicities or imbalances.
- Salinity** Is characterized by high electrical conductivities and low sodium ion concentrations compared to calcium and magnesium.
- Salverform** Applies to a gamopetalous corolla having a slender tube and an abruptly expanded limb.
- Samara** An indehiscent, winged, dry fruit.
- Sand** A naturally occurring granular material composed of finely divided rock and mineral particles range in diameter from 0.0625 µm to 2 mm. *Adj.* sandy
- Saponins** Are plant glycosides with a distinctive foaming characteristic. They are found in many plants, but get their name from the soapwort plant (*Saponaria*).
- Saprophytic** Living on and deriving nourishment from dead organic matter.
- Sapwood** Outer woody layer of the tree just adjacent to and below the bark.
- Sarcotesta** Outermost fleshy covering of Cycad seeds below which is the sclerotesta.
- Scabrid** Scurfy, covered with surface abrasions, irregular projections or delicate scales.

- Scabrous** Rough to the touch because of scattered rough hairs.
- Scale** Dry bract or leaf.
- Scandent** Refer to plants, climbing.
- Scape** Erect flowering stem, usually leafless, rising from the crown or roots of a plant. *Adj.* scapose.
- Scapigerous** With a scape.
- Scarious** Dry, thin and membranous.
- Schizocarp** A dry fruit which splits into longitudinally multiple parts called mericarps or cocci. *Adj.* schizocarpous.
- Sclerotesta** The innermost fleshy coating of cycad seeds, usually located directly below the sarcotesta.
- Scorpioid** Refers to a cymose inflorescence in which the main axis appears to coil.
- Scutellum (Botany)** Any of various parts shaped like a shield.
- Secondary Venation** Arrangement of the lateral veins arising from the midrib in the leaf lamina.
- Secund** With the flowers all turned in the same direction.
- Sedge** A plant of the family Apiaceae, Cyperaceae.
- Segmented** Constricted into divisions.
- Seminal Root** Or seed root originate from the scutellar node located within the seed embryo and are composed of the radicle and lateral seminal roots.
- Senescence** Refers to the biological changes which take place in plants as they age.
- Sepal** Free segment of the calyx. *Adj.* sepaline.
- Septum** A partition or cross wall. *Pl.* septa; *Adj.* septate.
- Seriate** Arranged in rows.
- Sericeous** Silky; covered with close-pressed, fine, straight silky hairs.
- Serrate** Toothed like a saw; with regular, asymmetric teeth pointing forward.
- Serrated** Toothed margin.
- Serratures** Serrated margin.
- Serrulate** With minute teeth on the margin.
- Sessile** Without a stalk.
- Seta** A bristle or stiff hair. *Pl.* setae; *Adj.* setose, setaceous.
- Setaceous** Bristlelike.
- Setate** With bristles.
- Setiform** Bristle shaped.
- Setulose** With minute bristles.
- Sheathing** Clasping or enveloping the stem.
- Shrub** A woody plant usually less than 5 m high and many branched without a distinct main stem except at ground level.
- Silicula** A broad, dry, usually dehiscent fruit derived from two or more carpels which usually dehisce along two sutures. *Cf.* siliqua.
- Siliqua** A silicula which is at least twice as long as broad.
- Silt** Is soil or rock derived granular material of a grain size between sand and clay, grain particles ranging from 0.004 to 0.06 mm in diameter. *Adj.* silty.
- Simple** Refer to a leaf or other structure that is not divided into parts. *Cf.* compound.
- Sinuate** With deep wavy margin.
- Sinuuous** Wavy.
- Sinus** An opening or groove, occurring between the bases of two petals.
- Sodicity** Is characterized by low electrical conductivities and high sodium ion concentrations compared to calcium and magnesium.
- Sodic Soils** Contains high levels of sodium salts that affect soil structure, inhibits water movement and causes poor germination and crop establishment and plant toxicity.
- Soil pH** Is a measure of the acidity or basicity of the soil. See pH.
- Solitary** Usually refers to flowers which are borne singly and not grouped into an inflorescence or clustered.
- Sorocarp** Fruiting body formed by some cellular slime moulds and has both stalk and spore mass.
- Sorophore** Stalk bearing the sorocarp.
- Sorosis** Fleshy multiple fruit formed from flowers that are crowded together on a fleshy stem, e.g. pineapple and mulberry.
- Sorus** A discrete aggregate of sporangia in ferns. *Pl.* sori
- Spadix** Fleshy spike-like inflorescence with an unbranched, usually thickened axis and small embedded flowers often surrounded by a spathe. *Pl.* spadices.
- Spathe** A large bract ensheathing an inflorescence or its peduncle. *Adj.* spathaceous.
- Spatheate** Like or with a spathe.
- Spatulate** Spatula or spoon shaped; broad at the tip and narrowed towards the base.

- Spicate** Borne in or forming a spike.
- Spiculate** Spikelet bearing.
- Spike** An unbranched, indeterminate inflorescence with sessile flowers or spiklets. *Adj.* spicate, spiciform.
- Spikelet** A small or secondary spike characteristics of the grasses and sedges and generally composed of 2 glumes and one or more florets. Also applied to the small spike-like inflorescence or inflorescence units commonly found in Apiaceae.
- Spine** A stiff, sharp, pointed structure, formed by modification of a plant organ. *Adj.* spinose.
- Spinescent** Ending in a spine; modified to form a spine.
- Spinulate** Covered with small spines.
- Spinulose** With small spines over the surface.
- Spodosol** see Podsol.
- Sporidia** Asexual spores of smut fungi.
- Sporangium** A spore-bearing structure found in ferns, fern allies and gymnosperms. *Pl.* sporangia; *Adj.* sporangial.
- Sporocarp** A stalked specialized fruiting structure formed from modified sporophylls, containing sporangia or spores as found in ferns and fern allies.
- Sporophore** A spore-bearing structure, especially in fungi.
- Sporophyll** A leaf or bract which bears or subtends sporangia in the fern allies, ferns and gymnosperms.
- Sporophyte** The spore-producing phase in the life cycle of a plant that exhibits alternation of generations.
- Spreading** Bending or spreading outwards and horizontally.
- Spur** A tubular or saclike extension of the corolla or calyx of a flower.
- Squama** Structure shaped like a fish scale. *Pl.* squamae.
- Squamous** Covered in scales.
- Squarrose** Having rough or spreading scale-like processes.
- Stamen** The male part of a flower, consisting typically of a stalk (filament) and a pollen-bearing portion (anther). *Adj.* staminal, staminate.
- Staminate** Unisexual flower-bearing stamens but no functional pistils.
- Staminode** A sterile or abortive stamen, often reduced in size and lacking anther. *Adj.* staminodial.
- Standard** Refers to the adaxial petal in the flower of Papilionaceae. Cf. keel, wing.
- Starch** A polysaccharide carbohydrate consisting of a large number of glucose units joined together by glycosidic bonds α -1-4 linkages.
- Stellate** Star shaped, applies to hairs.
- Stem** The main axis of a plant, developed from the plumule of the embryo and typically bearing leaves.
- Sterile** Lacking any functional sexual parts which are capable of fertilization and seed production.
- Stigma** The sticky receptive tip of an ovary with or without a style which is receptive to pollen.
- Stilt Root** A supporting root arising from the stem some distance above the ground as in some mangroves, sometimes also known as a prop root.
- Stipe** A stalk that support some other structure like the frond, ovary or fruit.
- Stipel** Secondary stipule at the base of a leaflet. *Pl.* stipellae. *Adj.* stipellate.
- Stipitate** Having a stalk or stipe, usually of an ovary or fruit.
- Stipulated** Having stipules.
- Stipule** Small leaflike, scale-like or bristlelike appendages at the base of the leaf or on the petiole. *adj.* stipulate.
- Stolon** A horizontal, creeping stem rooting at the nodes and giving rise to another plant at its tip.
- Stoloniferous** Bearing stolon or stolons.
- Stoma** A pore in the epidermis of the leaf or stem for gaseous exchange. *Pl.* stomata.
- Stone** The hard endocarp of a drupe, containing the seed or seeds.
- Stramineous** Chaffy; straw liked.
- Striae** Parallel longitudinal lines or ridges. *Adj.* striate.
- Striate** Marked with fine longitudinal parallel lines or ridges.
- Strigose** Bearing stiff, straight, closely appressed hair; often the hairs have swollen bases.
- Strobilus** A cone-like structure formed from sporophylls or sporangiophores. *Pl.* strobili
- Strophile** An appendage at the hilum of certain plant seeds.

- Strophiolate** Furnished with a strophile or caruncle.
- Style** The part of the pistil between the stigma and ovary.
- Sub-** A prefix meaning nearly or almost, as in subglobose or subequal.
- Subcarnose** Nearly fleshy.
- Subfamily** Taxonomic rank between the family and tribe.
- Subglobose** Nearly spherical in shape.
- Subretuse** Faintly notched at the apex.
- Subsessile** Nearly stalkless or sessile.
- Subshrub** Intermediate between a herb and shrub.
- Subspecies** A taxonomic rank subordinate to species.
- Substrate** Surface on which a plant or organism grows or attached to.
- Subtend** Attached below something.
- Subulate** Narrow and tapering gradually to a fine point, awl shaped.
- Succulent** Fleshy, juicy, soft in texture and usually thickened.
- Suckers** Young plants sprouting from the underground roots of a parent plant and appearing around the base of the parent plant.
- Suffrutescent Stem** Stem woody at the base.
- Sulcate** Grooved longitudinally with deep furrows.
- Sulcus** A groove or depression running along the internodes of culms or branches.
- Superior** Refers to the ovary is free and mostly above the level of insertion of the sepals and petals. *Cf.* inferior.
- Suture** Line of dehiscence.
- Swidden** Slash and burn or shifting cultivation.
- Syconium** A type of pseudocarp formed from a hollow receptacle with small flowers attached to the inner wall. After fertilization the ovaries of the female flowers develop into one-seeded achenes, e.g. fig.
- Symbiosis** Describes close and often long-term mutualistic and beneficial interactions between different organisms.
- Sympetalous** Having petals united.
- Sympodial** Refers to a specialized lateral growth pattern in which the apical meristem is terminated. *Cf.* monopodial.
- Synangium** An organ composed of united sporangia, divided internally into cells, each containing spores. *Pl.* synangia.
- Syncarp** An aggregate or multiple fruit formed from two or more united carpels with a single style. *Adj.* syncarpous.
- Syncarpous** Carpels fused forming a compound pistil.
- Synteny** Presence of two or more genetic loci on the same chromosome.
- Tannins** Group of plant-derived phenolic compounds.
- Taxon** The taxonomic group of plants of any rank, e.g. a family, genus, species or any infra-specific category. *Pl.* taxa.
- Tendrill** A slender, threadlike organ formed from a modified stem, leaf or leaflet which, by coiling around objects, supports a climbing plant.
- Tepal** A segment of the perianth in a flower in which all the perianth segments are similar in appearance and are not differentiated into calyx and corolla; a sepal or petal.
- Tetrasporangium** A sporangium containing four haploid spores as found in some algae.
- Terete** Having a circular shape when cross-sectioned or a cylindrical shape that tapers at each end.
- Terminal** At the apex or distal end.
- Ternate** In threes as of leaf with three leaflets.
- Testa** A seed coat, outer integument of a seed.
- Thallus** Plant body of algae, fungi and other lower organisms.
- Thyrse** A dense, panicle-like inflorescence, as of the lilac, in which the lateral branches terminate in cymes.
- Tomentose** Refers to plant hairs that are bent and matted forming a woolly coating.
- Tomentellose** Mildly tomentose.
- Torus** Receptacle of a flower.
- Transpiration** Evaporation of water from the plant through leaf and stem pores.
- Tree** That has many secondary branches supported clear of the ground on a single main stem or trunk.
- Triangular** Shaped like a triangle, three angled and three sided.
- Tribe** A category intermediate in rank between subfamily and genus.
- Trichome** A hair-like outgrowth of the epidermis.
- Trichotomous** Divided almost equally into three parts or elements.
- Tridentate** Three toothed or three pronged.

- Trifid** Divided or cleft into three parts or lobes.
- Trifoliate** Having three leaves.
- Trifoliolate** A leaf having three leaflets.
- Trifurcate** Having three forks or branches.
- Trigonus** Obtusely three angled; triangular in cross-section with plane faces.
- Tripartite** Consisting of three parts.
- Tripinnae** Relating to leaves, pinnately divided three times with pinnate pinnules.
- Tripliveined** Main laterals arising above base of lamina.
- Tripliod** Describing a nucleus or cell that has three times ($3n$) the haploid number (n) of chromosomes.
- Triveined** Main laterals arising at the base of lamina.
- Triquetrous** Three edged; acutely three angled.
- Trullate** With the widest axis below the middle and with straight margins; ovate but margins straight and angled below middle, trowel shaped, angular ovate.
- Truncate** With an abruptly transverse end as if cut off.
- Tuber** A stem, usually underground, enlarged as a storage organ and with minute scale-like leaves and buds. *Adj.* tuberous.
- Tubercle** A wart-like protuberance. *Adj.* tuberculate.
- Tuberculate** Bearing tubercles; covered with warty lumps.
- Tuberization** Formation of tubers in the soil.
- Tuft** A densely packed cluster arising from an axis. *Adj.* tufted.
- Turbinate** Having the shape of a top; cone shaped, with the apex downward, inversely conic.
- Turgid** Distended by water or other liquid.
- Turion** The tender young, scaly shoot such as asparagus, developed from an underground bud without branches or leaves.
- Turnery** Articles made by the process of turning.
- Twining** Winding spirally.
- Ultisols** Mineral soils with no calcareous material, have less than 10 % weatherable minerals in the extreme top layer of soil and with less than the 35 % base saturation throughout the soil.
- Umbel** An inflorescence of pedicellate flowers of almost equal length arising from one point on top of the peduncle. *Adj.* umbellate.
- Umbellet** A secondary umbel of a compound umbel. *Cf.* umbellule.
- Umbellule** A secondary umbel of a compound umbel. *Cf.* umbellet.
- Uncinate** Bent at the end like a hook; unciform.
- Undershrub** Subshrub; a small, usually sparsely branched woody shrub less than 1 m high. *Cf.* shrub.
- Undulate** With an edge/margin or edges wavy in a vertical plane; may vary from weakly to strongly undulate or crisped. *Cf.* crisped.
- Unifoliate** A compound leaf which has been reduced to a single, usually terminal leaflet.
- Uniform** With one form, e.g. having stamens of a similar length or having one kind of leaf. *Cf.* dimorphic.
- Uniseriate** Arranged in one row or at one level.
- Unisexual** With one sex only, either bearing the anthers with pollen, or an ovary with ovules, referring to a flower, inflorescence or individual plant. *Cf.* bisexual.
- Urceolate** Shaped like a jug, urn or pitcher.
- Utricle** A small bladderly pericarp.
- Valvate** Meeting without overlapping, as of sepals or petals in bud. *Cf.* imbricate.
- Valve** One of the sections or portions into which a capsule separates when ripe.
- Variant** Any definable individual or group of individuals which may or may not be regarded as representing a formal taxon after examination.
- Variegate, Variegated** Diverse in colour or marked with irregular patches of different colours, blotched.
- Variety** A taxonomic rank below that of subspecies.
- Vein (Botany)** A strand of vascular bundle tissue.
- Veinlets** Small veins.
- Velum** A flap of tissue covering the sporangium in the fern, Isoetes.
- Velutinous** Having the surface covered with a fine and dense silky pubescence of short fine hairs; velvety. *Cf.* sericeous
- Venation** Distribution or arrangement of veins in a leaf.
- Veneer** Thin sheet of wood.
- Ventral (Botany)** Facing the central axis, opposed to dorsal.

- Vernation** The arrangement of young leaves or fronds in a bud or at a stem apex. *Cf.* circinate.
- Verrucose** Warty.
- Verticil** A circular arrangement, as of flowers, leaves, or hairs, growing about a central point; a whorl.
- Verticillaster** False whorl composed of a pair of opposite cymes as in Lamiaceae.
- Verticillate** Whorled, arranged in one or more whorls.
- Vertisol** A soil with a high content of expansive montmorillonite clay that forms deep cracks in drier seasons or years.
- Vertosols** Soils that both contain more than 35 % clay and possess deep cracks wider than 5 mm during most years.
- Vesicle** A small bladdery sac or cavity filled with air or fluid. *Adj.* vesicular.
- Vestigial** The remaining trace or remnant of an organ which seemingly lost all or most of its original function in a species through evolution.
- Vestiture** Covering; the type of hairiness, scabiness or other covering commonly found on the external parts of plants. *Cf.* indumentums.
- Vibratile** Capable of to-and-fro motion.
- Villose** Covered with long, fine, soft hairs, finer than in pilose.
- Villous** Covered with soft, shaggy unmatted hairs.
- Vine** A climbing or trailing plant.
- Violaxanthin** Is a natural xanthophyll pigment with an orange colour found in a variety of plants like pansies.
- Viscid** Sticky, being of a consistency that resists flow.
- Viviparous** Describes seeds or fruit which sprout before they fall from the parent plant.
- Whorl** A ringlike arrangement of leaves, sepals, stamens or other organs around an axis.
- Winged** Having a flat, often membranous expansion or flange, e.g. on a seed, stem or one of the two lateral petals of a Papilionaceous flower or one of the petal-like sepals of Polygalaceae. *Cf.* keel, standard.
- Xanthophylls** Are yellow, carotenoid pigments found in plants. They are oxidized derivatives of carotenes.
- Xeromorphic** Plant with special modified structure to help the plant to adapt to dry conditions.
- Xerophyte** A plant which naturally grows in dry regions and is often structurally modified to withstand dry conditions.
- Zygomorphic** Having only one plane of symmetry, usually the vertical plane, referring to a flower, calyx or corolla. *Cf.* actinomorphic.
- Zygote** The first cell formed by the union of two gametes in sexual reproduction. *Adj.* zygotic.

Common Name Index

A

- Aaron's Rod, 32
Abyssinian Cabbage, 39
Acacia Bark, 58
Acacia Trinervis, 58, 738
Acorn Squash, 54
Acquired immuno deficiency syndrome (AIDS), 190, 355, 847
Action Plant, 821
Acyclovir-resistant HSV-1, 412
Adam's Needle, 23, 134
Adam's Needle Yucca, 134
Adenoviruses (ADV-3, ADV-8, ADV-11), 769
Adenovirus types 3 and 11, 356
Adriatic Bellflower, 46
African Aloe, 20
African Coffee Tree, 58
African Fan Palm, 16
African Flame Tree, 559
African Ivory Nut Palm, 17
African Marigold, 32, 432
African Palmyra Palm, 16
African Senna, 62
African Spider Flower, 51
African Tulip, 561, 568
African Tulip Tree, 37, 559, 561, 568
Agapetes, 56
Agathi, 806, 889, 890, 892
Agati Sesbania, 889
Agave, 111, 112, 117, 119, 137
Ageratum, 175
Aguamiel, 18
Airelle, 57
Alecost, 24
Alecrim Da Parede, 23
Alexanders, 11, 444
Alfalfa, 65
Algerian Tea, 51
Alkali Bulrush, 55
Alkanet, 37, 38
Allegheny Barberry, 35
Aloe, 20
Aloe Yucca, 22
Alpine Bluebell, 47
Alpine Leek, 9
Alpine Richea, 57
Alpine Rock Cress, 39
Alsike Clover, 68
Altai Onion, 5
Altamisa, 473, 474
Alyssum, 628–631
Amboyna Wood, 836, 838
Ambung, 16
American Aloe, 18
American Beech, 69
American Burnweed, 29
American Coral Tree, 63
American Cranberrybush, 4
American Cranberrybush Viburnum, 4
American Green Alder, 36
American Marigold, 432
American Red Elder, 3
American Saffron, 469
American Sea Rocket, 42
American Wild Ginger, 18
American Wintercress, 39
American Wisteria, 69
American Yellowrocket, 39
Amra, 9
Anchusa, 37
Andaman Redwood, 836
Angelica, 10
Angled Luffa, 54
Angled Onion, 9
Angsana, 65, 836, 837, 839
Annual Bluebell, 47
Annual Camomile, 397
Annual Pink, 694
Annual Sea Blite, 5
Annual Sunflower, 372
Annual Wall Rocket, 43
Antelope Horns, 12
Ant-Plant, 65, 821
Appa Grass, 175
Arctic Butterbur, 30
Arctic Sweet Coltsfoot, 30
Arenga Palm, 16
Aren Gelora, 16
Arizona Barrel Cactus, 45
Arnica, 493, 511
Aroma Doble, 58, 738
Arremene, 886

Arrowleaf Balsam Root, 24
 Arrowleaf Sweet Coltsfoot, 31
 Artichoke, 25, 27–31, 292–320, 374, 522
 Artichoke Thistle, 28, 291
 Arugula, 43
 Asafoetida, 10
 Ashoka Tree, 66
 Asian Palmyra Palm, 16
 Asian Pigeonwing, 773
 Asian Pumpkin, 53
 Asian Watermeal, 15
 Asiatic Dayflower, 52
 Asparagus Broccoli, 594
 Asparations®, 624, 625
 Aspen Onion, 5
 Assyrian Plum, 38
 Aster, 493
 Asthma Weed, 58
 Ataco, 4
 August Flower, 889
 Austral Bluebell, 48
 Australian Bluebell, 47
 Australian Corkwood Tree, 889
 Autumn Pumpkin, 54
 Avaram Senna, 29, 860
 Azalea, 56, 253, 265
 Aztec Dahlia, 333
 Aztec Marigold, 32, 432, 440, 442

B

Babbington's Leek, 5
 Baby Broccoli, 624
 Bachelor's Button, 25, 245, 473, 501
 Bad Man's Plaything, 139
 Bai Jiang Cao, 49
 Bainswort, 204
 Bairnwort, 204
 Bakersfield Beavertail, 46
 Ball-Head Onion, 8
 Balloon Flower, 47
 Balsam, 24, 35, 537–544, 548, 549
 Balsam Herb, 24

 Bedstraw Milkweed, 12
 Beebread, 68, 925
 Beech, 69
 Bee Spider-Flower, 51
 Beeswing Narra, 836
 Beggars Buttons, 24
 Beggar's Tick, 25, 70
 Begonias, 35, 551, 552, 556, 557
 Belle Of The Night, 45
 Bellflower, 46, 47
 Beltsville Bunching Onion, 9
 Bengal Arum, 15
 Bergaalwyn, 20
 Bible Leaf, 24
 Bidi Leaf Tree, 60
 Bigberry Manzanita, 56
 Bigelow's Beggarticks, 25
 Big Marigold, 432
 Big-Root Dandelion, 33
 Bigseed Biscuit Root, 11
 Bigseed Lomatium, 11
 Big Stem Mustard, 40
 Bilberry, 45, 57
 Bilberry Cactus, 45
 Billy Button, 204
 Billygoat-Weed, 24, 175
 Bimi, 624
 Bird Lime Tree, 38
 Bird-of-Paradise Flower, 766
 Bird-of-Paradise Shrub, 60
 Bird Vetch, 68
 Bitter Aloe, 20
 Bitter Buttons, 33, 501
 Bittercress, 39
 Bitter Gourd, 54
 Bitter Melon, 54
 Bitterweed, 24
 Bizzy-Lizzie, 35, 548, 550
 Black Caraway, 11
 Black cohosh, 936, 937
 Black Elder, 3
 Black-Fibre Palm, 16
 Black Ipecac, 51
 Black Knapweed, 26
 Black Locust, 66
 Black Lovage, 11
 Black mulberry, 529
 Black Mustard, 40
 Black Oil Plant, 51
 Black Oil Tree, 51
 Black pepper, 191, 283, 801, 900
 Black Rhun Palm, 16

Black Sampson, 340
 Blackwood, 58
 Blackwood Cassia, 873
 Blanco's Narra, 836, 839
 Bleaberry, 57
 Blessed Milk Thistle, 31
 Blessed Thistle, 27
 Blood Amaranth, 4
 Blood Red Spiral Costus, 53, 728
 Bloodwort, 139
 Blowball, 34, 516
 Blue Agave, 19
 Bluebell, 47
 Blueberry, 57
 Blueblow, 245
 Bluebonnets, 245
 Blue Bottle, 25, 123, 245
 Blue Bugloss, 37
 Blue Butterfly Pea, 773
 Blue Candle, 45
 Blue Cap, 245
 Blue Chamomile, 30, 397
 Blue cornflower, 247, 248
 Blue Devil, 38
 Blue Echium, 38
 Blue Elder, 3
 Blue Elderberry, 2, 3
 Blue Flame, 45
 Blue-Leafed Wattle, 59
 Blue Myrtle Cactus, 45
 Blue Pea, 62, 773
 Blue poppy, 245
 Blue Thistle, 38
 Blue Top, 175
 Blue Weed, 38
 Bohemia, 64
 Bois Immortel, 788
 Bolander's Onion, 5
 Bolivian Begonia, 35
 Bombay Aloe, 19
 Bombay Blackwood, 66, 873
 Boobyalla, 59
 Borage, 38, 70
 Border Carnation, 684
 Boreal Vetch, 68
 Boston Daisy, 201
 Bottle Gourd, 54
 Boutonniere Flower, 25, 245
 Bowl Clover, 68
 Brampton Stock, 633
 Branching Beavertail, 46
 Brazil Cress, 163
 Brazilian Fireweed, 29
 Brazilian Teak, 58
 Brazil nut, 376
 Bread Flower, 14
 Bridal Roses, 473
 British Myrrh, 11
 Britsly Locust, 66
 Broad-Leaved Clover, 925

Broad-Leaved Mustard, 40
 Broad-Lobed Dandelion, 516
 Broccolette, 624
 Broccoletti, 624
 Broccoli, 5, 11–13, 39–44, 571, 572, 574–577, 580, 585, 586, 588, 594–617
 Raab, 41
 sprouts, 601–603, 605, 609, 610, 612–616
 Broccolini, 40, 598, 624–626
 Broken Bones Plant, 37
 Bronze Bluebell, 47
 Broom, 62, 66, 531
 Brown Hemp, 28
 Bruisewort, 24, 204
 Brush Caper Berry, 48
 Brussels sprouts, 576, 579, 586, 597, 601, 611
 Buah Amra, 9
 Bucayo, 63
 Buckley's Yucca, 22
 Buffalo Gourd, 53
 Buffalo Herb, 65
 Bulberry, 57
 Bulbil Onion, 6, 7
 Bulb Onion, 6
 Bull Clover, 68
 Bull's Eye, 213
 Bur Artichoke, 28, 291
 Buriti Palm, 17
 Burma Creeper, 698
 Burmese Rosewood, 836, 839
 Burnet Saxifrage, 11
 Burning Bush, 52
 Burr Medic, 65
 Bush Banana, 13
 Busnay, 15
 Busy Lizzie, 35, 550
 Busy Lizzy, 548
 Butterbur, 31
 Buttercup Squash, 54
 Butter Daisy, 30
 Butterfly Ash, 60, 754
 Butterfly Needles, 25
 Butterfly Pea, 62, 773, 779, 780, 784
 Butterfly Pea Flower, 773
 Butterfly Tree, 60, 743, 754
 Butterfly Weed, 13
 Butternut Squash, 54

C

Cabbage, 237, 265, 576, 579, 585, 586, 597, 599, 610
 Cabbage Leaf Mustard, 40
 Cactus Dahalia, 28
 Cactus Pear, 46
 Caisin, 42
 Caixin, 41, 42
 Calabashes, 54
 Calabash Gourd, 54
 Calabrese, 41, 594, 606

- Calcivirus, 357
Calendula, 25, 70, 213, 214, 220, 226–228, 230, 235, 237
California Burclover, 65
California Clover, 65
Californian Redbud, 62
Cambodian Palm, 16
Camel's Foot, 60, 743
Camel's Foot Tree, 60, 754
Camomile, 24, 26, 397
Camphor Geranium, 473
Canada Garlic, 7
