Introduction

This book continues as volume 7 of a multi-compendium on *Edible Medicinal and Non-Medicinal Plants*. It covers plants with edible flowers whose floral parts including the stalk and flower nectar are eaten as conventional or functional food, as spice, and may provide a source of food colourant, additive or nutraceuticals. According to Health Canada (2002), a *functional food* is similar in appearance to, or may be, a conventional food that is consumed as part of a usual diet and is demonstrated to have physiological benefits and/or reduce the risk of chronic disease beyond basic nutritional functions, i.e. they contain bioactive compound. A *nutraceutical* is a product isolated or purified from foods that is generally sold in medicinal forms not usually associated with foods and is demonstrated to have a physiological benefit or provide protection against chronic disease. Biologically active components in functional foods that may impart health benefits or desirable physiological effects include the following: carotenoids (β -carotene, lutein, lycopene), dietary fibres (β -glucans, soluble fibre), fatty acids (omega fatty acids, conjugated linoleic acid), flavonoids (anthocyanins, flavanols, flavanones, flavonols, proanthocyanidins), isothiocyanates, phenolic acids, plant sterols, polyols and prebiotics/probiotics (fructooligosaccharides—inulin), vitamins and phytoestrogens (isoflavones—diadzein, genistein). Many plants with edible flowers contain many of these bioactive components and essential mineral elements (Mlcek and Rop 2011; Rop et al. 2012), carbohydrates and amino acids in the flowers and

other plant parts, imparting a wide array of health benefits and pharmacological properties. According to the Global Industry Analyst Inc., global nutraceuticals market is anticipated to exceed US 243 billion by 2015 (GIA 2012). The United States, Europe and Japan dominate the global market, accounting for a combined market share of more than 85 %. Spurred by the growing affluence, rising disposable income and increasing awareness, particularly in China and India, the Asia-Pacific region is projected to see significant growth in the long term. Functional foods that constitute the faster growing segment in the nutraceuticals market are rising in popularity, as the segment offers a cheaper alternative to dietary supplements. Value-added food products that feature edible flowers offer additional marketing opportunities.

This volume covers selected plant species with edible flowers from families Acanthaceae to Facaceae in a tabular form (Table 1) and 75 such species from the families Amaryllidaceae, Apocynaceae, Asclepiadaceae, Asparagaceae, Asteraceae, Balsaminaceae, Begoniaceae, Bignoniaceae, Brassicaceae, Cactaceae, Calophyllaceae, Caprifoliaceae, Caryophyllaceae, Combretaceae, Convolvulaceae, Costaceae, Doryanthaceae and Fabaceae in detail. Some plants with edible flowers, but are better known for their edible fruits, have been covered in earlier volumes and for other non-floral parts will be covered in subsequent volumes. Other plants with edible flowers from the family Geraniaceae to Zygophyllaceae will be covered in volume 8. The edible flower

Table 1 Plants with edible flowers in the families Acanthaceae to Fagaceae

Scientific name	English/common vernacular name	Flower edible uses	References
Acanthaceae			
<i>Adhatoda vasica</i> Nees	Malabar nut	Flowers are eaten	Sawian et al. (2007)
<i>Beloperone californica</i> Benth.	Red Justicia, Chuparosa	Red flowers are eaten raw or cooked	Clarke (1977), Facciola (1990)
<i>Justicia adhatoda</i> L.	Malabar Nut; Boga Bahak (Assamese); Nongmangkha Angoutba (Manipur)	Flowers are eaten fried in Assam	Patiri and Borah (2007), Yumnum and Tripathi (2012)
<i>Phlogacanthus curviflorus</i> (Wallich) Nees	Dhapa Tita (Assamese)	Young inflorescences and flowers are eaten as vegetables in Assam	Patiri and Borah (2007), Medhi and Borthakur (2012)
<i>Phlogacanthus thyrsoformis</i> (Roxb. ex Hardow) Mabb.	Ronga Bhahak, Titaphul, Titabahak (Assamese); Nongmankha (Manipur)	Flowers are bitter in taste and eaten as roasted vegetable by covering with banana leaf. Sometimes flowers are kept dried for future use. In Manipur, the people use the flowers in a dish called 'kangngou', a dry-fried dish. Another popular dish is 'sumtak', a bitter-tasting dish in which the flowers are fried in oil with small fish	Patiri and Borah (2007), Hauzel (2012)
Phlogacanthus tubiflorus Nees			
<i>Rhinacanthus nasutus</i> (L.) Kurz.	Snake Jasmine; Thong Phan Chang (Thai)	Dry/fresh inflorescences eaten in Assam Flowers reported edible	Medhi and Borthakur (2012) Wongwattanasathien et al. (2010)
<i>Strobilanthes scaber</i> Nees	Raspatia (Assamese); Sam Siphra (Meghalaya)	Flowers are commonly eaten by the Garo communities in assam and in Meghalaya	Patiri and Borah (2007)
Adoxaceae			
<i>Sambucus callicarpa</i> Greene = <i>Sambucus racemosa</i> var. <i>arborescens</i> (Torr. & A. Gray) A. Gray	Red Coast Elder	Flowers are eaten raw or cooked	Huxley et al. (1992), Fern (1992–2003)
<i>Sambucus canadensis</i> L.	American Elder, Canadian Elderberry	Flowers are dried and used for tea	Fernald et al. (1958), Facciola (1990), Barash (1997), Lauderdale and Evans (1999), McCullough (2007)
<i>Sambucus cerulea</i> Raf. = <i>Sambucus nigra</i> var. <i>cerulea</i> (Raf.) B.L. Turner	Blue Elderberry	Blossoms added to pancake to lighten batter and add flavour, used in tea and muffins	Barash (1997), Schofield (2003)
<i>Sambucus gaudichaudiana</i> DC.	White Elderberry	Flowers are eaten raw or cooked	Wikipedia (2012)

<i>Sambucus glauca</i> Nutt. = <i>Sambucus cerulea</i> Raf.	Blue Elderberry, Blue Elder	Blossoms added to pancake to lighten batter and add flavour, also ingredient for cakes and waffles. Dried flowers can be ground and added to baking mixes and flour. Also used for elder fritters	Schofield (2003)
<i>Sambucus javanica</i> Reinw. ex Blume	Chinese Elder	Flowers are eaten raw or cooked	Facciola (1990)
<i>Sambucus melanocarpa</i> A. Gray = <i>Sambucus racemosa</i> var. <i>melanocarpa</i> (A. Gray) McMinn	Black Elder	Blossoms added to pancake to lighten batter and add flavour, also ingredient for cakes and waffles. Dried flowers can be ground and added to baking mixes and flour. Also used for elder fritters	Schofield (2003)
<i>Sambucus mexicana</i> auct. = <i>Sambucus cerulea</i> Raf.	Mexican Elder	Flowers eaten raw or cooked. Flower clusters dipped in batter, fried and sprinkled with sugar. Flowers shaken from stem to add flavour to pancakes, muffins and cakes	Uphof (1968), Clarke (1977), Facciola (1990)
<i>Sambucus microbotrys</i> Rydb. = <i>Sambucus racemosa</i> var. <i>microbotrys</i> (Rydb.) Kearney and Peebles	Red Elder	Flowers eaten raw or cooked	Kunkel (1984), Moerman (1998)
<i>Sambucus nigra</i> L.	Elderberry	Flowers fried in fritters, blossom eaten as sweet fritter or added to steamed fruit, jams, jellies, vinegar, make into elderflower wine, sparkling champagne. Blossoms added to pancake to lighten batter and add flavour, also ingredient for cakes and waffles. Dried flowers can be ground and added to baking mixes and flour. Also for elder fritters	MacNicol (1967), Hedrick (1972), Cribb and Cribb (1975), Tanaka (1976), Low (1989), Facciola (1990), Garland (1993), Burnie and Fenton-Smith (1996), Schofield (2003)
<i>Sambucus pubens</i> Michx. = <i>Sambucus racemosa</i> subsp. <i>pubens</i> (Michx.) House	American Red Elder	Blossoms added to pancake to lighten batter and add flavour	Schofield (2003)
<i>Sambucus racemosa</i> subsp. <i>kamischaticca</i> (E.L. Wolf) Hulten	Red Elder	Blossoms added to pancake to lighten batter and add flavour	Schofield (2003)
<i>Sambucus racemosa</i> L.	Red Elder	Blossoms added to pancake to lighten batter and add flavour	Schofield (2003)
<i>Sambucus sieboldiana</i> (Miq.) Blume ex Graebn.	Elderberry	Buds boiled and eaten as vegetables or used as substitute for tea	Tanaka (1976)
<i>Viburnum edule</i> Raf.	Mooseberry, Highbush Cranberry	Flowers added to pancake and cake batters. Blossoms can also be batter-dipped and fried	Schofield (2003)

(continued)

Table 1 (continued)

Scientific name	English/common vernacular name	Flower edible uses	References
<i>Viburnum trilobum</i> Marshall	American Cranberrybush Viburnum, American Cranberrybush, Kalyna, Highbush, Highbush Cranberry	Flowers can be mixed with pancake or muffin batter or can be made into fritters	Deane (2007–2012u)
Aizoaceae			
<i>Carpobrotus deliciosus</i> (L. Bolus) L. Bolus	Sweet Hottentot Fig, Pigface	Edible flowers, also fruits and leaves (pickled)	King (2007)
<i>Carpobrotus edulis</i> (L.) N.E.Br.	Hottentot Fig, Ice Plant	Edible flowers, also fruits and leaves (pickled)	King (2007)
<i>Carpobrotus glaucescens</i> (Haw.) Schwantes	Coastal Noon Flower, Pigface	Pink flowers eaten, also fruits and leaves (pickled)	King (2007)
Alismataceae			
<i>Limncharis flava</i> (L.) Buchenau	Yellow Burhead	Young unopened inflorescence and peduncle eaten	Ochse and van den Brink (1980), Tanaka and Nguyen (2007), van den Bergh (1994)
<i>Sagittaria latifolia</i> Willd.	Wapato, Duck Potato, Indian Potato	White flowers edible	Deane (2007–2012f)
Amaranthaceae			
<i>Alternanthera sessilis</i> (L.) R.Br. ex DC.	Dwarf Copperleaf, Sessile Joyweed; Chuk-Tsit-Tsoi (Chinese)	Flowers are eaten in China	Facciola (1990), Uphof (1968), Tanaka (1976)
<i>Amaranthus cruentus</i> L.	Blood Amaranth, Purple Amaranth, Red Amaranth	Flowers are used to colour ceremonial maize bread in Guatemala	Facciola (1990)
<i>Amaranthus quitensis</i> Kunth	Ataco, Sangorache	Red inflorescences—source of dye used for colouring chicha and ceremonial maize dishes	Kunkel (1984), Facciola (1990)
<i>Amaranthus</i> sp. (<i>Amaranthus cruentus</i> × <i>Amaranthus powelli</i>)	Hopi Red Dye Amaranth	Water extract of flower clusters used to colour the pink maize wafer bread	Facciola (1990)
<i>Amaranthus viridis</i> L.	Green Amaranth, Slender Amaranth	Leaves, leafy stem and flower cluster used as spinach substitute.	Tanaka (1976), Cribb and Cribb (1987), Kunkel (1984), Ochse and van den Brink (1980), Facciola (1990)
<i>Atriplex canescens</i> (Pursh.) Nutt.	Four-Wing Salt Bush, Grey Sage Bush	Yellow flowers edible	Wilson (2012)
<i>Atriplex</i> spp.	Salt Bush	All parts including flowers are edible	McCullough (2007)
<i>Celosia argentea</i> L.	Plumed Cockscomb, Quailgrass, Soko	Leaves, stem and young inflorescences steamed and eaten as potherb or finely cut and used in soups	Dalziel (1937), Ochse and Bakhuizen van den Brink (1980), Facciola (1990)
<i>Celosia cristata</i> L. = <i>Celosia argentea</i> var. <i>cristata</i> (L.) Kuntze	Toreador Cockscomb; Maendrami Hwajeon (Korean)	Flowers used in 'hwajeon' cake in Korea	Anonymous (2012b)
<i>Chenopodium album</i> L.	Fat Hen	Young inflorescences are cooked	Fernald et al. (1958), Facciola (1990)

<i>Chenopodium bonus-henricus</i> L.	Good King Henry	Young flower buds are cooked	Organ (1960), Hedrick (1972), Facciola (1990)
<i>Chenopodium cornutum</i> (Torr.) Benth. and Hook.f. ex Watson	Goosefoot	Flowers eaten in Arizona	Yanovsky (1936)
<i>Chenopodium ficifolium</i> Sm.	Fig-Leaved Goosefoot	Flower buds eaten in soups, vegetable dishes, fried, roasted or parboiled and as potherb	Tanaka (1976), Facciola (1990)
<i>Chenopodium nuttalliae</i> Saff. = <i>Chenopodium quinoa</i> Willd.	Quinoa; Huauzontle	Flower clusters eaten cooked, used like broccoli; they are considered a gourmet food	Phillips and Rix (1998), Facciola (1990)
<i>Suaeda maritima</i> (L.) Dumort.	Annual Sea Blite	Green flowers eaten	Maisuthisakul et al. (2008), Maisuthisakul (2012)
Amaryllidaceae			
<i>Allium acuminatum</i> Hook.	Hooker's Onion, Tapertip Onion	Flowers raw, used as a garnish on salads	Moerman (1998), Fern (1992–2003)
<i>Allium aflatumense</i> B. Fedtsch.	Ornamental Onion; Kirgislök (Swedish)	Flowers raw, used as a garnish on salads	Fern (1992–2003)
<i>Allium akaka</i> S. G. Gmel. ex Schult. and Schult. F.	None	Flowers raw, used as a garnish on salads	Fern (1992–2003)
<i>Allium altaicum</i> Pall.	Altai Onion; Songino (Mongolia)	Flowers raw, used as a garnish on salads	Fern (1992–2003)
<i>Allium ampeloprasum</i> var. <i>babingtonii</i> (Borrer) Syme = <i>Allium ampeloprasum</i> L.	Babington's Leek, Wild Leek	Flowers raw, used as a garnish on salads. Flowers best used as a flavouring in cooked food	Fern (1992–2003)
<i>Allium ampeloprasum</i> L.	Leek	Flowers raw, used as a garnish on salads	Fern (1992–2003), Sulistiorini and van der Meer (1994)
<i>Allium angulare</i> Pall. = <i>Allium angulosum</i> L.	None	Flowers raw, used as a garnish on salads	Fern (1992–2003)
<i>Allium angulosum</i> L.	Mouse Garlic	Flowers raw, used as a garnish on salads	Fern (1992–2003)
<i>Allium ascalonicum</i> L.	Red Shallots; Hom (Thai)	Young inflorescences eaten	Ochse and van den Brink (1980), Maisuthisakul et al. (2008), Maisuthisakul (2012)
<i>Allium atropurpureum</i> Waldst. and Kit.	Purple-Flowered Onion	Flowers raw, used as a garnish on salads	Fern (1992–2003)
<i>Allium bisceptrum</i> S. Watson	Aspen Onion	Flowers raw, used as a garnish on salads	Fern (1992–2003)
<i>Allium bodeanum</i> auct. = <i>Allium walteri</i> Regel.	None	Flowers raw, used as a garnish on salads	Fern (1992–2003)
<i>Allium bolanderi</i> S. Watson	Bolander's Onion	Flowers raw, used as a garnish on salads	Fern (1992–2003)
<i>Allium brevistylum</i> S. Watson	Short-Style Onion	Flowers raw, used as a garnish on salads	Fern (1992–2003)

<i>Allium dregeanum</i> Kunth	Wild Onion	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium drummondii</i> Regel	Prairie Onion	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium fistulosum</i> L.	Welsh Onion	Flowers eaten raw, used as garnish on salads	Oyen and Soenoeadi (1994), Fern (1992–2003)
<i>Allium flavum</i> L.	Small Yellow Onion	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium galanthum</i> Kar. and Kir.	None	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium geyeri</i> var. <i>tenerum</i> M.E. Jones	Bulbil Onion, Geyer's Onion	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium giganteum</i> Regel	Giant Onion	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium grayi</i> Regel = <i>Allium macrostemon</i> Bunge	Chinese Garlic, Japanese Garlic, Water Garlic	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium hookeri</i> Thwaites	Hooker Chives	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium kunthii</i> G. Don	Kunth's Onion	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium kurrat</i> Schweinf. Ex K. Krause	Kurrat, Egyptian Leek	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium ledebourianum</i> Schult. and Schult. F.	Giant Siberian Chives; Asatsuki (Japanese)	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)

<i>Allium macleanii</i> Baker	Maclean Onion	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium macropetalum</i> Rydb.	Large Flower Onion	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium macrostemon</i> Bunge	Macrostemon Onion, No-Binu	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium moly</i> L.	Golden Garlic	Flowers eaten raw, have a pleasant onion flavour and used as garnish on salads	Fern (1992–2003)
<i>Allium monanthum</i> Maxim.	Wild Chive; Dan Hua Xie (Chinese); Hime Nira (Japanese)	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium mutabile</i> Michx. = <i>Allium canadense</i> var. <i>canadense</i>	Canada Garlic, Meadow Garlic, Wild Onion	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium neapolitanum</i> Cirillo	Daffodil Garlic	Flowers eaten raw or cooked, excellent in salads	Fern (1992–2003)
<i>Allium obliquum</i> L.	Twisted leaf Garlic, Lopsided Ornamental Onion	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium oleraceum</i> L.	Field Garlic	Flowers eaten raw, used as garnish on salads and as flavouring in soups and stews	Facciola (1990), Fern (1992–2003)
<i>Allium orientale</i> Boisse	Oriental Onion	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium oschaninii</i> O. Fedtsch.	French Gray Shallot	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium paradoxum</i> (M. Bieb.) G. Don	Few-Flowered Leek	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium pendulinum</i> Ten.	Italian Garlic	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium platycaule</i> S. Watson	Flat-Stem Onion	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium porrum</i> L. = <i>Allium ampeloprasum</i> L.	Leek, Garden Leek	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium przewalskianum</i> Regel	Ladakh Onion, Flowering Onion, Przewalski's Onion	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium ramosum</i> L.	Flowering Leek, Fragrant-Flowered Garlic	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium roseum</i> L.	Rosy Garlic	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium rubellum</i> M. Bieb	None	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium rubrum</i> Osterh. = <i>Allium geyeri</i> var. <i>tenerum</i> M.E. Jones	Bulbil Onion, Geyer's Onion	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium ruhmerianum</i> Asch. ex E.A. Durand and Barratte	None	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium sacculiferum</i> Maxim.	None	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)

(continued)

Table 1 (continued)

Scientific name	English/common vernacular name	Flower edible uses	References
<i>Allium sativum</i> L.	Garlic	Flower peduncles used as vegetable	Tanaka (1976), Facciola (1990), Woodward (2000), van der Meer and Permadi (1994)
<i>Allium sativum</i> var. <i>ophioscorodon</i> (Link) Döll	Ophio Garlic, Spanish Garlic	Flower peduncles used as vegetable	Facciola (1990), Fern (1992–2003)
<i>Allium schoenoprasum</i> L.	Garden Chives	Flowers eaten fresh, tossed in salads or made into herb vinegars and butters; flowers simmered in soups, eaten in salads or dipped in batter and fried as fritters; flowers eaten in omelette, cheese and fish dishes or used as garnish	Burnie and Fenton-Smith (1996), Schofield (2003), Tanaka (1976), Facciola (1990), Lauderdale and Evans (1999), Roberts (2000), Newman and O'Connor (2009)
<i>Allium schoenoprasum</i> subsp. <i>sibiricum</i> Hayek and Markgraf = <i>Allium schoenoprasum</i> L.	Garden Chives	The bulb, root, leaves and flowers of most <i>Allium</i> plants are edible, although only the bulbs or leaves are usually consumed, depending on species	Facciola (1990)
<i>Allium scorodoprasum</i> L.	Rocambole	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium scorodoprasum</i> subsp. <i>rotundum</i> (L.) Stearn = <i>Allium rotundum</i> subsp. <i>rotundum</i>	Sand Leek; Ail Arrondi (French)	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium semenovii</i> Regel	Semenov's Onion	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium senescens</i> L.	German Garlic	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium sphaerocephalon</i> L.	Round-Headed Leek, Round-Headed Garlic, Ball-Head Onion	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium splendens</i> Willd.ex Schult. and Schult.f.	Glittering Onion; Miyama-Rakkyo (Japanese)	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium stellatum</i> Nutt. Ex Ker Gawl.	Prairie Onion	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium stipitatum</i> Regel	Persian Shallot	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium stracheyi</i> Baker	Dunna, Pharan (Central Himalaya)	Flowers eaten raw; used as a garnish on salads; used as condiment in Central Himalaya	Laferriere (1992), Fern (1992–2003)
<i>Allium suaveolens</i> Jacq.	Fragrant Onion	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium subhirsutum</i> L.	Hairy Garlic	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium textile</i> A. Nelson and J. F. Macbr.	Textile Onion	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium thunbergii</i> G. Don	Japanese Onion	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)

<i>Allium tricoccum</i> Sol.	Wood Leek	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium triquetrum</i> L.	Angled Onion, Three-Cornered Garlic	Flowers eaten raw; juicy with a mild garlic flavour, they make a tasty and decorative garnish on salads	Fern (1992–2003)
<i>Allium tuberosum</i> Rottler ex Spreng.	Garlic Chives	Inflorescence, flowers, unopened flower buds and flower peduncle used in Asian cooking Chive flowers have a mild onion flavour and are surprisingly crunchy. They are widely used tossed in salads, pasta, omelettes and scrambled eggs. They can be added to white fish dishes or to cheese sauce to give that extra bite	Van der Meer (1994), Facciola (1990), Woodward (2000), Tanaka and Nguyen (2007), Newman and O'Connor (2009), Anonymous (2012a)
<i>Allium unifolium</i> Kellogg	One-Leaved Onion	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium ursinum</i> L.	Wild Garlic	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium validum</i> S. Watson	Pacific Onion, Pacific Mountain Onion, Swamp Onion, Wild Onion,	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium victorialis</i> L.	Alpine Leek	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium wallichii</i> Kunth	Jimbur	Flowers eaten raw, used as garnish on salads	Fern (1992–2003)
<i>Allium x proliferum</i> (Moench) Schrad. ex Willd.	Beltsville Bunching Onion, Egyptian Onion, Top Onion	Inflorescence bulbils, bulbs and leaves used as spice	Siedmann (2005)
<i>Narcissus jonquilla</i> L.	Jonquil	Flowers eaten raw or candied and made into desserts	Crowhurst (1972), Facciola (1990)
<i>Tulbaghia alliacea</i> L.f.	Society Garlic	Flowers regarded as a delicacy by the native Zulu women	Facciola (1990), Newman and O'Connor (2009)
<i>Tulbaghia violacea</i> Harv.	Society Garlic	Flowers eaten raw or cooked; added to salads, used as a garnish or as a flavouring in cooked foods	Facciola (1990), Harris (1975)
Anacardiaceae			
<i>Mangifera indica</i> L.	Mango	Flowers are edible	Facciola (1990)
<i>Pistacia terebinthus</i> L.	Turpentine Tree	Flowers edible raw	Deane (2007–2012w)
<i>Spondias malayana</i> Kostermans	Malaysian Hog, Malaysian Mombin Plum	Inflorescence used as food flavouring	Jansen (1999)
<i>Spondias mangifera</i> Willd. = <i>Spondias pinnata</i> (L.f.) Kurz	Hog Plum, Malayan Mombin, Amra, Buah Amra	Tender panicles eaten steamed or dressed as salad, sour flowers used as flavouring	Burkill (1966), Ochse and van den Brink (1980), Facciola (1990)
Anthericaceae			
<i>Dichopogon fimbriatus</i> (R.Br.) J.F. Macbride	Nodding Chocolate Lily		Harden (1993)

(continued)

Table 1 (continued)

Scientific name	English/common vernacular name	Flower edible uses	References
<i>Dichopogon strictus</i> (R.Br.) Baker	Chocolate Lily		Harden (1993)
Apiaceae			
<i>Anethum graveolens</i> L.	Dill	Inflorescences used to flavour pickled cucumbers, onions, vinegar, sauces, gravies, stews, pastries and bread. Flowers added to fish dishes and omelettes or sprinkle over cooked vegetables. Whole flowers are added to pickled gherkins, cucumbers or beetroots	Hedrick (1972), Facciola (1990), Garland (1993), Van den Bergh (1994a, b), Lauderdale and Evans (1999), Newman and O'Connor (2009), Anonymous (2012a)
<i>Angelica archangelica</i> L.	Angelica, Garden Angelica, Holy Ghost, Wild Celery, Norwegian Angelica	Flowers are excellent with fish and the flower stems are especially popular candied; flowers used in pastries, cakes and confectionary	Uphof (1968), Tanaka (1976), Facciola (1990), Deane (2007–2012x)
<i>Anthriscus cerefolium</i> (L.) Hoffm.	Chervil, French Parsley	Flowers used as seasoning	Hedrick (1972), Facciola (1990), Lauderdale and Evans (1999), Newman and O'Connor (2009)
<i>Bunium bulbocastanum</i> L.	Earth Chestnut, Pignut	Flowers and seeds used as condiment	Uphof (1968), Tanaka (1976), Kunkel (1984), Facciola (1990)
<i>Carum carvi</i> L.	Caraway	Flowers used in salads, peach 'pashka'	Roberts (2000)
<i>Cogswellia nudicaulis</i> M.E. Jones	Barestem Biscuitroot	Flowers used as beverage	Yanovsky (1936)
<i>Coriandrum sativum</i> L.	Coriander	The flowers are as adaptable as the leaves in a variety of different dishes. Flowers are scattered over cauliflower, added to the end of a stir-fry or added to cream cheese. A few flowers are scattered over an orange fruit salad to enhance the flavour. Some dishes include aubergine and coriander lunch dish; leeks, kale and coriander flower soup; green bean and potato salad with coriander flowers	Roberts (2000), Newman and O'Connor (2009), Kaisoon et al. (2011), Anonymous (2012a)
<i>Crithium maritimum</i> L.	Samphire, Rock Samphire	Raw blossoms used in salad	Deane (2007–2012q)
<i>Cryptotaenia canadensis</i> (L.) DC.	Honewort, Wild Chervil	Young leaves, stems and flowers eaten raw or cooked as potherb	Tanaka (1976), Kunkel (1984), Facciola (1990)
<i>Cryptotaenia japonica</i> Hassk.	Mitsuba, Japanese Honewort, Japanese Parsley	Flowers are edible cooked	Deane (2007–2012p)
<i>Daucus carota</i> L.	Carrot, Queen Anne's Lace, Wild Carrot	The flower clusters can be french fried to produce a carrot-flavoured gourmet's delight	Facciola (1990)
<i>Ferula assa-foetida</i> L.	Asafoetida, Devil's Dung	Immature flower heads eaten fresh	Garland (1993)

<i>Foeniculum vulgare</i> Mill.	Fennel, Sweet Fennel	Flowers used in fruit pies	Barash (1997), Lauderdale and Evans (1999), Roberts (2000), Newman and O'Connor (2009)
<i>Heracleum lanatum</i> Michx.	Cow Parsnip, Indian Celery, Pushki	Young flowers eaten	Yanovsky (1936)
<i>Heracleum maximum</i> Bartr.	Common Cow Parsnip	Flower stalks and leaf petioles peeled and eaten fresh	Perry (1952), Turner et al. (1980)
<i>Heracleum sphondylium</i> subsp. <i>montanum</i> (Schleich. ex Gaudin.) Briq. = <i>Heracleum lanatum</i> Michx.	Cow Parsnip, Indian Celery, Pushki	Young flowers are eaten	Uphof (1968), Usher (1974), Tanaka (1976)
<i>Levisticum officinale</i> W.D.J. Koch	Lovage, Garden Lovage	Flowers are eaten	Facciola (1990), Lauderdale and Evans (1999)
<i>Lomatium macrocarpum</i> (Hook. & Arn.) J.M. Coul. and Rose = <i>Lomatium hallii</i> (S. Watson) J.M. Coul. and Rose	Bigseed Biscuit Root, Bigseed Lomatium	Tea prepared from flowers	Facciola (1990)
<i>Lomatium nudicaule</i> (Pursh) J.M. Coul. and Rose	Beach Dill, Hogfennel, Indian Celery, Naked Desert Parsley, Naked-Stemmed Pestle Parsnip, Wild Celery,	An infusion of leaves, stems and flowers used as a beverage	Hedrick (1972), Facciola (1990)
<i>Myrrhis odorata</i> (L.) Scop.	Sweet Cicely, Cicely, Greater Chervil, Roman Plant, Cow Chervil, Smooth Cicely, Sweet Fern, British Myrrh, Shepherd's Needle, Sweets	The sweet anise-flavoured flowers are lovely added to apple, plum or rhubarb tarts	Brown (2011)
<i>Pimpinella saxifraga</i> L.	Black Caraway, Burnet Saxifrage, Greater Burnet, Saxifrage Burnet	Flower heads made into wine	Facciola (1990)
<i>Saposhnikovia divaricata</i> (Turcz.) Schischk.	Siler Root, Fang Feng (Chinese)	Leaves, flowers boiled used as tea	Hu (2005)
<i>Smyrniolum olusatrum</i> L.	Alexanders, Black Lovage	Flower buds eaten raw, added to salads	Larkcom (1980), Loewenfeld and Back (1978)
<i>Smyrniolum perfoliatum</i> L.	Perfoliate Alexanders	Flower buds eaten raw, added to salads	Larkcom (1980), Loewenfeld and Back (1978)
<i>Trachyspermum roxburghianum</i> (DC.) H. Wolff	Wild Celery; Ajmod (Hindi); Ajamodika (Sanskrit); Phakchee Rai, Phak Sangae (Thai)	Young plants are harvested and consumed fresh as side dish or added to soup. Dried whole plant with inflorescence is used as spice to flavour curries	Jircas (2010)
<i>Zizia aurea</i> W.D.J. Koch.	Golden Alexanders	The flowers, minus pedicels, are tossed in green salad. They are also a delicious cooked vegetable when used in a similar manner to broccoli	Facciola (1990)

Table 1 (continued)

Scientific name	English/common vernacular name	Flower edible uses	References
Apocynaceae			
<i>Asclepias asperula</i> (Decne.) Woodson	Antelope Horns	Unopened flower buds eaten cooked. They taste somewhat like peas. They are used like broccoli. Flowers are used as a flavouring and a thickener in soups. The flower clusters can be boiled down to make a sugary syrup	Harrington (1974), Harris (1975), Facciola (1990), Kavasch (2005)
<i>Asclepias galioides</i> H. B. K.	Bedstraw Milkweed	Young buds eaten by boys of Zufii Indians of New Mexico	Yanovsky (1936)
<i>Asclepias hallii</i> A. Gray	Purple Silkweed	Flower buds eaten raw or cooked, taste like peas	Balls (1962), Usher (1974)
<i>Asclepias incarnata</i> L.	Swamp Milkweed	Unopened flower buds eaten cooked. They taste somewhat like peas. They are used like broccoli. Flowers are used as a flavouring and a thickener in soups. The flower clusters can be boiled down to make a sugary syrup	Yanovsky (1936), Uphof (1968), Usher (1974), Facciola (1990)
<i>Asclepias lanceolata</i> Walter	Purple Silkweed	Flowers edible	Wikipedia (2012)
<i>Asclepias mexicana</i> Cav.	Mexican Milkweed	Young blossoms eaten cooked	Yanovsky (1936), Kunkel (1984)
<i>Asclepias ovalifolia</i> Decne.	Oval-Leaved Milkweed, Dwarf Milkweed	Unopened flower buds eaten cooked. They taste somewhat like peas. They are used like broccoli. Flowers are used as a flavouring and a thickener in soups. The flower clusters can be boiled down to make a sugary syrup	Hedrick (1972), Harris (1975), Facciola (1990), Kavasch (2005)
<i>Asclepias pumila</i> (A. Gray) Vail.	Low Milkweed	As above	Harrington (1974), Facciola (1990), Kavasch (2005)
<i>Asclepias purpurascens</i> L.	Purple Milkweed	Flower buds eaten raw or cooked	Usher (1974), Elias and Dykeman (2009)
<i>Asclepias quadrifolia</i> Jacq.	Fourleaf Milkweed	Unopened flower buds eaten cooked. They taste somewhat like peas. They are used like broccoli. Flowers are used as a flavouring and a thickener in soups. The flower clusters can be boiled down to make a sugary syrup	Harrington (1974), Harris (1975), Kavasch (2005)
<i>Asclepias rubra</i> L.	Red Silkweed	The flower clusters can be boiled down to make a sugary syrup	Coffey (1993)

<i>Asclepias speciosa</i> Torr.	Showy Milkweed	Flowers eaten raw or boiled in Montana and California; buds boiled for soup or with meat	Yanovsky (1936), Balls (1962), Usher (1974)
<i>Asclepias syriaca</i> L.	Common Milkweed, Milkweed	Unopened flower buds eaten cooked. They taste somewhat like peas. They are used like broccoli. Flowers are used as a flavouring and a thickener in soups. The flower clusters can be boiled down to make a sugary syrup. Flowers stewed by Chippewa Indians	Yanovsky (1936), Harrington (1974), Harris (1975), Facciola (1990), Moerman (1998), Kavasch (2005)
<i>Asclepias tuberosa</i> L.	Butterfly Weed, Canada Root, Chigger Flower, Chiggerflower, Fluxroot, Indian Paintbrush, Indian Posy	Flowers produce so much nectar that crystallizes out into small lumps which can then be eaten like sweets. The flower clusters can also be boiled down to make a sugary syrup	Yanovsky (1936), Harrington (1974), Facciola (1990)
<i>Asclepias viridiflora</i> Raf.	Green Milkweed	Flowers eaten and used like common milkweed	Harris (1975), Facciola (1990)
<i>Dregea volubilis</i> (L.f.) Benth. ex Hook.f.	Sneeze Wort; Kratung-Maba (Thai)	Young shoot and inflorescence, which are available year-round, are cooked in a curry with dried, smoked fish	Jircas (2010)
<i>Fernaldia pandurata</i> (A. DC.) Woodson	Loroco, Quilite (El Salvador, Guatemala, Mexico)	Loroco is small green unopened flower buds used as an herb for flavouring in Central America. It is used in salads, rice dishes, stews and sauces. In El Salvador and in Honduras, it is added to the fillings in 'pupusas'	Facciola (1990), Morton et al. (1990)
<i>Holostemma rheedii</i> Wall.	Palay Keeray (Tamil); Pala Kura (Telugu)	Flowers eaten in India (Deccan)	Shortt (1887–1888), Watt (1908)
<i>Hoya viridiflora</i> (R.Br.) Griff	Hoya; Cooringee Keeray (Tamil)	Flowers eaten uncooked or prepared into a 'bhaji'. Flower powder (said to be pollen) is removed from the flowers and used in the preparation of 'Dhoklas', a small, thick bread	Shortt (1887–1888), Gammie (1902), Paton and Dunlop (1904), Watt (1908)
<i>Leichhardtia australis</i> R.Br. = <i>Marsdenia australis</i> (R.Br.) Druce	Doubah, Bush Banana	Flowers, leaves, shoots, roots seed eaten	Low (1989)
<i>Leptadenia hastata</i> Vatke = <i>Leptadenia lancifolia</i> (Schumacher & Thonn.) Decne.	Idar; Cheila, Kayilla, Hayilla (Konsogna, Ethiopia); Moroh (Somali)	Flowers and tender shoots eaten like spinach	Dalziel (1937), Hedrick (1972), Facciola (1990)
<i>Morrenia odorata</i> (Hook. & Arn.) Lindl.	Milkweed Vine, Latex Plant, Strangler Vine	The flowers are very sweet and floral and can be eaten raw	Deane (2007–2012n)
<i>Orbea namaquensis</i> (N.E.Br.) Leach	Carion Flower, Orbea; Aasblom, Bokhoring (Afrikaans)	Flowers eaten	Aiyambo (2010)

<i>Pergularia daemia</i> (Forsk.) Chiov.	Trellis-Vine; Uтарan, Sagovani, Aakasan, Gadaria Ki Bel, Jutak (Hindi)	Flowers cooked as potherbs	Fox et al. (1982), Tanaka (1976), Facciola (1990)
<i>Plumeria obtusa</i> L.	Frangipani, Temple Flower, Pagoda Tree	Flowers popular in omelettes, fried, in salads, as dried herbal tea. The crispy and tasty flavour of the tempura style fried flowers may accompany 'Khanom Jeen Nam Ya' (Chinese spaghetti with fish curry soup). Flowers also eaten in sweetmeats	Wetwityaklung et al. (2008), Wongwattanasathien et al. (2010), Kaisoon et al. (2011)
<i>Plumeria rubra</i> L.	Frangipani, Temple Flower, Temple Tree, Tree of Life, West Indian Jasmine,	Flowers used as above	Burkill (1966), Kunkel (1984), Hu (2005)
<i>Rhyncharhena linearis</i> (Decne.) K.L. Wilson	Climbing Purple-Star, Purple Pentatropae	Flowers and buds eaten	Cribb and Cribb (1975)
<i>Telosma cordata</i> (Burm.f.) Merr.	Chinese Violet, Cowslip Creeper, Fragrant Telosma, Tonkin Creeper, Tonkin Jasmine; Thiên Lý, Hoa Lý, Hoa Lý (Vietnamese)	Flowers and young leaves eaten	Tanaka and Nguyen (2007)
<i>Telosma minor</i> (Andrews) Craib = <i>Telosma cordata</i> (Burm.f.) Merr.	Chinese Violet, Cowslip Creeper, Fragrant Telosma, Tonkin Creeper, Tonkin Jasmine	Flowers eaten raw or cooked in light curry, steamed or fried	Pongpangan and Poobrasert (1985), Wetwityaklung et al. (2008), Kaisoon et al. (2011)
<i>Telosma procumbens</i> (Blanco) Merrill	Cowslip Creeper; Latok (Tagalog), Cam Tháo Đá Bia (Vietnamese)	Flowers eaten in the Philippines	Van den Bergh (1994a, b)
<i>Vallaris heynei</i> Spreng. = <i>Vallaris solanacea</i> (Roth) O Kuntze	Bread Flower	Flowers eaten in Thailand	Burkill (1966), Facciola (1990)
<i>Vallaris solanacea</i> (Roth) O Kuntze	Bread Flower	Flowers eaten in Thailand	Van den Bergh (1994a, b)
<i>Wattakaka volubilis</i> (L.f.) Stapf = <i>Dregea volubilis</i> (L.f.) Benth. ex Hook.f.	Green Milkwood Climber	Young leaves, tender stem and green flowers cooked locally as vegetables	Pongpangan and Poobarasert (1985)
<i>Wrightia tinctoria</i> R.Br.	Dyers' Oleander, Pala Indigo Plant, Sweet Indrajao	Flowers are edible	Jukema et al. (1992)

Aponogetonaceae			
<i>Aponogeton distachyos</i> L.f.	Cape Pond Lily, Cape Asparagus, Water Hawthorn; Waterblommietjie (Afrikaans)	Flowering spike—pickled or used as a spinach or asparagus substitute. The flowers are used as a flavouring and flower buds used as a key ingredient in tempura, 'waterblommietjes' and in the traditional South African dish of 'waterblommietjie bredie' (lamb stew)	Uphof (1968), Hedrick (1972), Facciola (1990), Roberts (2000)
Araceae			
<i>Amorphophallus</i> spp.	Corpse Flower, Snake Plant; Buk (Thai)	Non-stinking flowers cooked for food	Pongpangan and Poobarasert (1985)
<i>Lasia spinosa</i> (L.) Thaw.	Spiny Taro; Chengmora (Assam); Phak Naam (Thai)	Flower spadix eaten cooked as vegetable	Patiri and Borah (2007)
<i>Peltandra virginica</i> (L.) Schott	Green Arrow Arum	Spadix (the flowering stem) and berries—cooked. A great delicacy, but they must be thoroughly well cooked otherwise they are poisonous	Uphof (1968), Hedrick (1972), Tanaka (1976)
<i>Schismatoglottis calyptrata</i> (Roxb.) Zollinger and Moritz	Guang Xi Luo Yan (Chinese); Dujaruk (Malay)	Inflorescences are eaten	Van den Bergh (1994a, b)
<i>Spathiphyllum phrynifolium</i> Schott.	Lirio, Busnay	Tender inflorescences eaten raw or used in soups or fried in egg batter	Martin and Ruberté (1975), Williams (1981), Facciola (1990)
<i>Typhonium trilobatum</i> (L.) Schott.	Bengal Arum, Lobed Leaf Typhonium; Syam Kachu, Sam Ghas, Sam Kochu (Assamese)	Spadix are eaten cooked as vegetable by Bodo and Rajbongshi people in Assam	Patiri and Borah (2007)
<i>Wolffia globosa</i> (Roxb.) Hartog and Plas	Asian Watermeal, Tropical Watermeal; Pham, Khai Nae, Khai Nam (Thai)	Inflorescences are eaten	Dadaung et al. (2011)
Araliaceae			
<i>Aralia armata</i> (Wallich ex G. Don) Seemann	Guang Dong Sonu Mu (Chinese); Tang Nok (Thai)	Young leaves, unopened flowers cooked, excellent	Pongpangan and Poobarasert (1985)
<i>Eleutherococcus gracilistylus</i> (W.W.Sm.) S.Y. Hu = <i>Eleutherococcus nodiflorus</i> (Dunn) S.Y.Hu	Wu Jia Pi, Xi Zhu Wu Jia (Chinese)	Flowers are edible	Kunkel (1984)
<i>Trevesia palmata</i> (Roxb. ex Lindl.) Vis.	Snowflake Aralia; Taang Luang (Thai)	Young flower buds, available by the end of rainy season, are eaten after cooking in hot and spicy curry in Thailand. Flower buds eaten cooked by Garos and Bodos peoples in Assam and in Meghalaya	Tanaka (1976), Facciola (1990), Patiri and Borah (2007), Jircas (2010), Medhi and Borthakur (2012)

Scientific name	English/common vernacular name	Flower edible uses	References
Arecaceae			
<i>Arenga ambong</i> Becc. = <i>Arenga undulatifolia</i> Becc.	Ambung, Aren Gelora	Buds are edible	Brown (1954), Tanaka (1976), Facciola (1990)
<i>Arenga engleri</i> Becc.	Formosan Sugar Palm	Buds are eaten, sap from inflorescence made into sugar	Tanaka (1976), Facciola (1990)
<i>Arenga pinnata</i> (Wurm) Merr.	Sugar Palm, Arenga Palm, Areng Palm, Black-Fibre Palm, Gomuti Palm, Aren	Sap from cut inflorescence stalk extracted to make palm sugar, jaggery, almost sap juice to make fresh drink, saguir or lightly fermented beverage, vinegar inflorescence peduncle tap for treacle, sugar, alcohol, toddy, tuba and vinegar; bids are cooked as a vegetable or pickled	Uphof (1968), Ochse and van den Brink (1980), Jones (1984), Facciola (1990), Smits (1996)
<i>Astrocaryum mexicanum</i> Lieb. ex Mart.	Chocho, Waree Palm	Flowers edible	Haynes and McLaughlin (2000)
<i>Borassus aethiopum</i> Mart.	African Fan Palm, African Palmyra Palm, Deleb Palm, Ron Palm, Toddy Palm, Black Rhun Palm, Ronier Palm	Sap from cut inflorescence stalk extracted to make palm sugar, jaggery Sap from cut inflorescence provides a drink; sap also processed into wine, alcohol or vinegar and dried into sugar cakes	Tanaka (1976), Jones (1984), Facciola (1990), Haynes and McLaughlin (2000)
<i>Borassus flabellifer</i> L.	Asian Palmyra Palm, Toddy Palm, Sugar Palm, Cambodian Palm	Sap from cut inflorescence stalk extracted to make palm sugar, jaggery, almost sap juice to make lightly fermented beverage, toddy	Menninger (1977), Jones (1984), Morton (1988), Facciola (1990), Haynes and McLaughlin (2000)
<i>Calyptronoma dulcis</i> (C. Wright ex Griseb.) L.H. Bailey = <i>Calyptronoma plumeriana</i> (Mart.) Lourteig	Manaca, Palma Manaca (Spanish)	Flowers used for making candy in Cuba	Kunkel (1984), Facciola (1990)
<i>Caryota urens</i> L.	Fish Tail Palm	Sap from cut inflorescence stalk extracted to make palm sugar, jaggery	Jones (1984)
<i>Chamaedorea costaricana</i> Oerst.	Parlour Palms	Young inflorescences (flower stems) are eaten raw, deep fried in batter or boiled or use in soups in Costa Rica	Williams (1981), Facciola (1990)
<i>Chamaedorea elegans</i> Mart.	Parlour Palm, Neanthe Bella Palm	Unopened inflorescences eaten raw or cooked	Haynes and McLaughlin (2000)
<i>Chamaedorea graminifolia</i> H. Wendl.	Pacaya, Xiat Palm	Unopened flower clusters eaten in salads, folded into egg batter and fried or used as boiled vegetables in Central America	Uphof (1968), Tanaka (1976), Williams (1981), Facciola (1990)

<i>Chamaedorea tepejilote</i> Liebm.	Pacaya Palm, Tepejilote Palm	Selectively propagated plants are grown for the young male inflorescences called 'pacaya' eaten raw, boiled or fried in egg batter	Hedrick (1972), Williams (1981), Facciola (1990), Haynes and McLaughlin (2000)
<i>Cocos nucifera</i> L.	Coconut	Sap from cut inflorescence stalk extracted to make palm sugar, jaggery, almost sap juice to make lightly fermented beverage, toddy, vinegar Yg infl enclosed in spathe eaten in lalab	Ochse and van den Brink (1980), Jones (1984)
<i>Collinia elegans</i> (Mart.) Liebm. ex Oerst. = <i>Chamaedorea elegans</i> Mart.	Parlour Palm, Neanthe Bella Palm,	Young unexpanded flower spikes eaten like asparagus	Uphof (1968), Hedrick (1972), Facciola (1990)
<i>Copernicia cerifera</i> (Arruda) Mart. = <i>Copernicia prunifera</i> (Mill.) H.E. Moore	Carnauba Wax Palm	Young inflorescence eaten	Tanaka (1976), Kunkel (1984), Facciola (1990)
<i>Corypha utan</i> Lam.	Gebang Palm, Ibus	Sap from inflorescence used to make wine and sugar	Haynes and McLaughlin (2000)
<i>Euglossona utilis</i> Becc.	Kadjatoa	Purple flower pollen used as condiment	Haynes and McLaughlin (2000)
<i>Guilielma gasipaes</i> (Kunth) L.H. Bailey = <i>Bactris gasipaes</i> Kunth var. <i>gasipaes</i>	Peach Palm, Pejibaye	Flowers may be chopped and added to salads	Facciola (1990)
<i>Hyphaene petersiana</i> Klotzsch ex Mart.	African Ivory Nut Palm	Palm wine made by fermenting mesocarp pulp and from sap by tapping flower bud (nondestructive)	Haynes and McLaughlin (2000)
<i>Iriartea ventricosa</i> Mart. = <i>Iriartea deltoidea</i> Ruiz and Pav.	Stilt Palm, Copa Palm, Barrigona Palm, Huacrapona	Flowers yield an ash used as a substitute for common salt in Guiana, Brazil	Tanaka (1976), Kunkel (1984), Facciola (1990)
<i>Mauritia flexuosa</i> L.f.	Buriti Palm, Wine Palm	Sap from the inflorescence is drunk or made into palm wine or sugar	Hedrick (1972), Cavalcante (1977), Facciola (1990)
<i>Nannorrhops ritchiana</i> (Griff.) Aitch.	Mazari Palm	Young inflorescences eaten	Watt (1908), Hedrick (1972), Tanaka (1976), Facciola (1990)
<i>Nypa fruticans</i> Wurm	Mangrove Palm, Nipa, Nipa Palm, Nipah, Golpata (Bangladesh, India)	Inflorescences cooked in nipa syrup to produce an energy-giving sweetmeat	Hedrick (1972), Facciola (1990)
<i>Oncosperma filamentosum</i> (Kunth) Blume = <i>Oncosperma tigillarum</i> (Jack) Ridl.	Nibung, Nibong, Nibung Palm	Flowers used to flavour rice in Malaysia	Burkill (1966), Hedrick (1972), Tanaka (1976), Facciola (1990)
<i>Phoenix canariensis</i> Chabaud	Canary Island Date Palm	Sap from cut inflorescence stalk extracted to make palm sugar	Jones (1984)

(continued)

Table 1 (continued)

Scientific name	English/common vernacular name	Flower edible uses	References
<i>Phoenix dactylifera</i> L.	Date Palm	Sap from cut inflorescence stalk extracted to make palm sugar, jaggery; male inflorescence eaten as delicacy	Jones (1984), Facciola (1990)
<i>Phoenix reclinata</i> Jacq.	Sengal Dat Eplam, Wild Date Palm; Wilde-Dadelboom (Afrikaans)	Sap from cut inflorescence stalk extracted to make palm sugar	Jones (1984)
<i>Phoenix sylvestris</i> (L.) Roxb.	Silver Date Palm, Toddy Palm, Wild Date Palm, India Date Palm, Date-Sugar Palm	Sap from cut inflorescence stalk extracted to make palm sugar	Jones (1984)
<i>Raphia hookeri</i> G. Mann and H. Wendl.	Raffia Palm, Wine Palm	Juice produced after removing immature inflorescence used to make wine	Hedrick (1972), Kunkel (1984), Facciola (1990), Haynes and McLaughlin (2000)
<i>Raphia vinifera</i> P. Beauv.	Bamboo Palm; King Bamboo Palm	Juice produced after removing immature inflorescence used to make wine	Hedrick (1972), Kunkel (1984), Facciola (1990), Haynes and McLaughlin (2000)
<i>Rhopalostylis sapida</i> (Sol. ex G. Forst.) H. Wendl. and Drude	Nika Palm, Nikau Palm	Young inflorescence eaten	Hedrick (1972), Facciola (1990)
<i>Trachycarpus fortunei</i> (Hook.) H. Wendl.	Chusan Palm, Chinese Windmill Palm	Unopened inflorescences eaten raw or cooked. The fresh flowers and terminal bud are also consumed	Hedrick (1972), Tanaka (1976), Stuart (1979), Facciola (1990), Haynes and McLaughlin (2000)
Aristolochiaceae			
<i>Aristolochia bracteata</i> Retz.	Dutchman's Pipe, Worm Killer; Um-Glaigla (Arabic)	Flowers used as a tea substitute in southern Kordofan, Sudan	Abdelmuti (1991) (cited by Freedman 2013)
<i>Asarum canadense</i> L.	American Wild Ginger	Flowers used as flavouring, have fragrance and taste liken to ginger	Facciola (1990)
Asparagaceae			
<i>Agave attenuata</i> Salm-Dyck	Century Plant, Foxtail Agave	Young fat flower stalks roasted	King (2007)
<i>Agave americana</i> L.	Aguamiel, Century Plant, Maguey, American Aloe	The sweet sap from the flowering stem is drunk or fermented into an alcoholic beverage pulque which open distillation yields the spirit mescal. Kickapoo Indians baked the flower stalks on hot stones and made into 'quite'	Facciola (1990), Deane (2007–2012a)
<i>Agave angustifolia</i> Haw.	Caribbean Agave	Young fat flower stalks roasted	King (2007)
<i>Agave atrovirens</i> Karw.ex Salm-Dyck	Century Plant, Maguey	Flower stalks roasted and eaten	Facciola (1990), Deane (2007–2012a)

<i>Agave cantala</i> (Haw.) Roxb. ex Salm-Dyck	Cantala, Bombay Aloe, Cebu Maguey, Manila Maguey	Flower stalks roasted and eaten	Deane (2007–2012a)
<i>Agave chrysantha</i> Peebles	Golden-Flowered Agave	Flower stalks roasted and eaten	Deane (2007–2012a)
<i>Agave complicata</i> Trel. ex Ochoa = <i>Agave americana</i> subsp. <i>americana</i>	Century Plant	Flower stalks roasted and eaten	Deane (2007–2012a)
<i>Agave crassipina</i> Trel. = <i>Agave salmiana</i> subsp. <i>crassipina</i> (Trel.) Gentry	Giant Agave, Pulque Agave	Flower stalks roasted and eaten	Deane (2007–2012a)
<i>Agave deserti</i> Engelm.	Desert Agave, Mescal, Century Plant, Maguey	Flowers and buds are eaten. Young flower stalks are baked until they form a sweet, starchy cake called 'mescal'. Nectar from flowers consumed directly by Indians	Tanaka (1976), Clarke (1977), Facciola (1990)
<i>Agave palmeri</i> Engelm.		Flower stalks roasted and eaten	Deane (2007–2012a)
<i>Agave parryi</i> Engelm.	Century Plant, Parry's Agave	Young fat flower stalks roasted and eaten, nectar from the flowering stalk made into a sweet syrup	Facciola (1990), Deane (2007–2012a)
<i>Agave salmiana</i> Otto ex Salm-Dyck	Pulque Agave, Century Plant	Flower stalks cut for 'quite' which is sold in the streets and chewed like sugarcane in southwestern America	Uphof (1968), Facciola (1990), Deane (2007–2012a)
<i>Agave shawii</i> Engelm.	Shaw's Agave, Century Plant	Sweet nectar is used in California	Yanovsky (1936)
<i>Agave shrevei</i> Gentry		Flower stalk eaten	Laferriere et al. (1991)
<i>Agave sisalana</i> Perrine	Century Plant	Flowers can be boiled or roasted. The stalks before they blossom in summer can also be roasted and taste like molasses. The sap obtained after removal of the stalk can be used to make tequila. Flower nectar can be used to make sauces or sugar and bottled	Deane (2007–2012a)
<i>Agave</i> spp.	Century Plant	Flowers edible	Stangland (2004), McCullough (2007)
<i>Agave stricta</i> Salm-Dyck	Century Plant, Needle Agave, Needle Leaf Agave, Globe Agave, Hedgehog Agave, Hedgehog Century Plant	Flowers lightly cooked and dipped in egg batter for frying	King (2007)
<i>Agave tequilana</i> F.A.C. Weber	Blue Agave, Century Plant	Flowers used as above	Deane (2007–2012a)
<i>Agave utahensis</i> Engelm.	Utah Agave, Century Plant	Flower stalks edible	Harrington (1974), Facciola (1990), Deane (2007–2012a)
<i>Agave vivipara</i> auct. non. = <i>Agave angustifolia</i> Haw.	Century Plant	Flowering stalks eaten in India	Watt (1908)

Table 1 (continued)

Scientific name	English/common vernacular name	Flower edible uses	References
<i>Aloe barteri</i> Baker = <i>Aloe tenuifolia</i> Lam.	African Aloe	Blossoms used as a soup vegetable in West Africa	Irvine (1952), Uphof (1968)
<i>Aloe candelabrum</i> A. Berger = <i>Aloe ferox</i> Mill.	Bitter Aloe, Red Aloe; Bitteraalwyn, Bergaalwyn (Afrikaans); Inhlaba (Zulu); Ikhalá (Xhosa)	Flowers sucked for nectar	Fox et al. (1982), Facciola (1990)
<i>Aloe chabaudii</i> Schönland		Flowers eaten as vegetables	Kunkel (1984), Facciola (1990)
<i>Aloe ferox</i> Mill	Cape Aloe, Bitter Aloe, Red Aloe (English); Bitteraalwyn, Bergaalwyn (Afrikaans); Inhlaba (Zulu); Ikhalá (Xhosa)	Flowers sucked for sweet nectar, sippable blossoms	Fox et al. (1982), Facciola (1990), Deane (2007–2012u)
<i>Aloe greatheadii</i> Schönland	Spotted Aloe; Transvaalaalwyn, Grasaalwyn (Afrikaans); Kgopane (Tswana)	Flower buds are a delicacy after being boiled	Kunkel (1984), Facciola (1990), Deane (2007–2012u)
<i>Aloe littoralis</i> Baker	Mopane Aloe; Bergaalwyn, Windhoekaalwyn, Mopanie-Aalwyn (Afrikaans)	Flowers used as potherbs	Fox et al. (1982), Facciola (1990)
<i>Aloe macrocarpa</i> Tod.	Aloe	Flowers eaten as vegetable	Fox et al. (1982), Facciola (1990)
<i>Aloe marlothii</i> A. Berger	Mountain Aloe	Flowers with nectar that can be consumed, sippable blossoms	Fox et al. (1982), Facciola (1990), Deane (2007–2012u)
<i>Aloe zebrina</i> Baker	Zebra Leaf Aloe, Spotted Aloe	Edible flowers and buds after being boiled. In Angola, they are pressed into cakes	Fox et al. (1982), Facciola (1990), Deane (2007–2012u)
<i>Aspidistra sutepensis</i> K. Larsen	Lilao (Thai)	Steamed flowers eaten as vegetable	Pongpangan and Poobrasert (1985), Maisuthisakul et al. (2008), Maisuthisakul (2012)
<i>Clitocyba brevifolia</i> (Engelm.) Rydb. = <i>Yucca brevifolia</i> Engelm.	Joshua Tree	Young flower buds roasted on hot coals	Yanovsky (1936)
<i>Convallaria keiskei</i> Miq.	Lily of the Valley, Susuran; Kimigage-So (Japanese)	The flowers and flower buds are preserved in salt or mixed with leaf tea and drunk	Tanaka (1976), Kunkel (1984), Facciola (1990)
<i>Convallaria majalis</i> L.	Lily of the Valley, Convall-Lily, Convallaria, Jacob's Ladder	In some parts of Germany, a wine is prepared from the flowers mixed with raisin	Grieve (1971), Facciola (1990)
<i>Dasyllirion texanum</i> Scheele	Texas Sotol, Sotol	Central bud roasted in mescal pits and used as food by Indians or made into a beverage	Uphof (1968), Facciola (1990)
<i>Dasyllirion wheeleri</i> S. Watson ex Rothr.	Common Sotol, Desert Spoon, Sotol	As above	Uphof (1968), Facciola (1990)

<i>Dichelostemma pulchellum</i> (Salisb.) Heller = <i>Dichelostemma congestum</i> (Sm.) Kunth.	Wild Hyacinth	Flowers eaten raw make a nice decoration in the salad bowl	Moerman (1998), Facciola (1990)
<i>Dichopogon finbriatus</i> (R.Br.) J.F. Macbr.	Nodding Chocolate Lily	Flowers are edible	Steenbeeke (2001)
<i>Dichopogon strictus</i> (R.Br.) J.G. Baker	Chocolate Lily Grass Lily	Flowers eaten raw; chocolate scented	Cribb and Cribb (1987)
<i>Hesperoyucca whipplei</i> (Torr.) Trel.	Chaparral Yucca	Flowers boiled and eaten	Yanovsky (1936), Tanaka (1976), Facciola (1990)
<i>Hosta</i> spp.	Plantain Lily	Flowers are edible	Deane (2007–2012k, t)
<i>Lomandra longifolia</i> Labill.	Longleaf Mat-Rush	Flowers eaten raw. Tiny creamy flowers eaten taste like peas with flower fragrance, flowers soaked in lemon juice, strained and base juice used as a fruit drink	Cribb and Cribb (1987), Low (1989)
<i>Lomandra</i> spp.	Mat Rush	Tiny creamy flowers eaten	Low (1989)
<i>Ornithogalum pyrenaicum</i> L.	Prussian Asparagus	Young unexpanded inflorescence cooked and served like asparagus vegetables	Grieve (1971), Facciola (1990)
<i>Ornithogalum umbellatum</i> L.	Star of Bethlehem	Flowers eaten baked in bread	Fernald et al. (1958), Hedrick (1972), Facciola (1990)
<i>Peltosanthus tetra</i> Andrews	China Lily; Cu Hua Qiu Zi Cao (Chinese)	The edible part is the inflorescence. This indigenous vegetable has become very popular and more cultivated in some rural areas of northern Thailand	Chaikla et al. (2011)
<i>Polianthes tuberosa</i> L.	Tuberose	Flowers eaten cooked; used in vegetable soups or added to the substrate of 'kecap', an Indonesian soy sauce. The flowers are the source of tuberosa-flower water	MacNicol (1967), Tanaka (1976), Facciola (1990), Roberts (2000)
<i>Samuela carnosana</i> Trel. = <i>Yucca carnosana</i> (Trel.) McKelvey	Palma Barreta	Young flower clusters eaten boiled or roasted in Mexico	Uphof (1968), Tate (1976), Facciola (1990)
<i>Sansevieria gracilis</i> N.E.Br.	Sansevieria	Flowers are edible	Kunkel (1984), Facciola (1990)
<i>Thysanotus patersonii</i> R.Br.	Fringed Lily	Flowers are edible	SERCUL (2011)
<i>Veltheimia bracteata</i> Harv.ex Baker	Winter Red Hot Poker, Forest Lily	Flowers eaten like spinach	Hedrick (1972), Kunkel (1984), Facciola (1990), Deane (2007–2012v)

(continued)

Table 1 (continued)

Scientific name	English/common vernacular name	Flower edible uses	References
<i>Yucca aloifolia</i> L.	Aloe Yucca, Spanish Bayonet	Flowers edible raw or cooked. They are delicious raw or can be dried, crushed and used as a flavouring. Flowering stem is peeled and boiled, used like asparagus	Morton (1977), Kunkel (1984), Facciola (1990)
<i>Yucca angustissima</i> Engelm. ex Trevir.	Narrow/leaf Yucca	As above	Harrington (1974)
<i>Yucca baccata</i> Torr.	Banana Yucca, Datil Yucca, Spanish Bayonet	Flower buds edible cooked. The older flowers are best as they are rich in sugar. The flowers, harvested before the summer rains, have been used as a vegetable. Flowering peduncles eaten cooked	Yanovsky (1936), Hedrick (1972), Sweet (1962), Harrington (1974), Clarke (1977), Facciola (1990), Stangland (2004), Elias and Dykeman (2009)
<i>Yucca brevifolia</i> Engelm.	Joshua Tree	Flowers edible cooked. The flower buds, before opening, can be parboiled in salt water to remove the bitterness, drained and then cooked again and served like cauliflower. The opened flowers are rich in sugar and can be roasted and eaten as candy	Tanaka (1976), Tate (1976), Facciola (1990)
<i>Yucca constricta</i> Buckley	Buckley's Yucca	Flowers edible raw or cooked. Delicious raw, they can also be dried, crushed and used as a flavouring. Flowering stem eaten cooked and used like asparagus	Bird (1990)
<i>Yucca elata</i> (Engelm.) Engelm.	Soap Tree Yucca	As above	Tate (1976), Kunkel (1984), Bird (1990), Moerman (1998)
<i>Yucca elephantipes</i> Regel	Spineless Yucca, Soft-Tip Yucca	Petals edible after removal of bitter anthers, used in salad and fried in batter	Uphof (1968), Facciola (1990)
<i>Yucca filamentosa</i> L.	Spoonleaf Yucca, Adam's Needles, Eve's Thread	Blossoms are edible raw or boiled. Flowers also dried, crushed and used as a flavouring. Petals used as garnish and salad. One Mexican dish is sauteed yucca flowers with chipotle	Hedrick (1972), Kunkel (1984), Bird (1990), Belsinger (1990), Facciola (1990), Newman and O'Connor (2009), Deane (2007–2012e, 2007–2012zb)
<i>Yucca filifera</i> Chadaub	Palm China, China Palm	Flowers edible raw or cooked. Delicious raw, they can also be dried, crushed and used as a flavouring. Flowering stem cooked and used like asparagus	Bird (1990)
<i>Yucca glauca</i> Nutt.	Soapweed Yucca	Flowers eaten raw in salad or cooked as potherbs, flower stalk cooked and inner portion eaten	Yanovsky (1936), Harrington (1974), Facciola (1990)
<i>Yucca gloriosa</i> L.	Spanish Dagger	Flowers edible raw or cooked. They are delicious raw and can also be dried, crushed and used as a flavouring. Flowering stem cooked and used like asparagus	Bird (1990)

<i>Yucca harrimaniae</i> Trel.	Spanish Bayonet, Spanish Dagger	As above	Harrington (1974), Bird (1990)
<i>Yucca mohavensis</i> Sarg. = <i>Yucca schidigera</i> Roehl ex Ortgies	Mojave Yucca	Flowers boiled for food, flowers eaten raw or used in jellies	Yanovsky (1936), Tanaka (1976), Facciola (1990)
<i>Yucca recurvifolia</i> Salisb. = <i>Yucca gloriosa</i> var. <i>recurvifolia</i> (Salisb.) Engelm.	Curveleaf Yucca; Pendulous Yucca	Flowers eaten raw or cooked. They are delicious raw, and can also be dried, crushed and used as a flavouring. A crisp crunchy texture, the flowers are very substantial and need to be well chewed. Flowering stem cooked and used like asparagus	Fern (1992–2003), Wikipedia (2012)
<i>Yucca rupicola</i> Scheele	Twisted-Leaf Yucca	As above	Wikipedia (2012)
<i>Yucca schidigera</i> Roehl ex Ortgies	Mojave Yucca	Young flowering stems chopped and cooked like asparagus or baked like a sweet potato	Bird (1990), Facciola (1990)
<i>Yucca smalli</i> ana Fernald = <i>Yucca flaccida</i> Haw.	Adam's Needle	Flowers eaten raw or cooked. They are delicious raw and can also be dried, crushed and used as a flavouring. Flowering stem cooked and used like asparagus	Bird (1990)
<i>Yucca</i> spp.	Yucca		
<i>Yucca whipplei</i> Torr. = <i>Hesperoyucca whipplei</i> (Torr.) Tre.	Our Lord's Candle	Flowers eaten raw or cooked	Uphof (1968), Usher (1974)
Asteraceae			
<i>Achillea borealis</i> Bong. = <i>Achillea millefolium</i> L. subsp. <i>borealis</i> (Bong.) Breitung	Milfoil	Flowers used as below	Schofield (2003)
<i>Achillea millefolium</i> L.	Common Yarrow, Sneezewort, Soldier's Friend, Thousand-Leaf	Flowers used in herbal teas and lemonade; flowers fried in butter sprinkled with sugar or orange juice. An essential oil derived from the flowering tops is used commercially for flavouring soft drinks and alcoholic drinks	Uphof (1968), Grieve (1971), Facciola (1990), Schofield (2003)
<i>Achillea ptarmica</i> (Willd.) Rupr. Ex Heimerl	Sneeze-Wort, Pearl Sneeze-Wort	Flowers used as above	Schofield (2003)
<i>Achillea sibirica</i> Ledeb. = <i>Achillea alpina</i> L.	Chinese Yarrow; Nokogiri-Sou (Japanese)	Flowers used as above	Schofield (2003)
<i>Achyrocline satureioides</i> (Lam.) DC.	Alecrim Da Parede, Macela, Marcala Do Campo (Brazil)	Flowers used for flavouring bitter spirits	Seidemann (2005)
<i>Acemella oleracea</i> (L.) R.K. Jansen	Para Cress, Toothache Plant, Szechuan Buttons	Flowers eaten	Wetwityaklung et al. (2008), Ochse and van den Brink (1980), Deane (2007–2012p)

(continued)

Table 1 (continued)

Scientific name	English/common vernacular name	Flower edible uses	References
<i>Actinea odorata</i> (A. Gray) Kuntze = <i>Actinella odorata</i> (DC.) A. Gray	Bitterweed	Infusion of flowering tops used as beverage in Texas	Yanovsky (1936)
<i>Ageratum conyzoides</i> L.	Billygoat-Weed, Chick Weed, Goatweed, Whiteweed	Fragrant flowers and foliage used for scenting coconut oil in south eastern Polynesia	Facciola (1990), Brown (2011)
<i>Anthemis nobilis</i> L. = <i>Chamaemelum nobile</i> (L.) All.	Camomile, Chamomile, Roman Chamomile, English Chamomile, Low Chamomile	Flower used to flavour food and brewed into tea. Flowers have a sweet apple flavour	Newman and O'Connor (2009)
<i>Arctium lappa</i> L.	Great Burdock, Gobo	Pith of flower stalk eaten raw in tossed salads, boiled as potherb or made into confection	Facciola (1990), Roberts (2000)
<i>Arctium minus</i> (Hill.) Benth.	Lesser Burdock, Beggars Buttons	Pith of flower stalk eaten raw in tossed salads or cooked as asparagus	Harrington (1974), Facciola (1990), Roberts (2000)
<i>Argyranthemum frutescens</i> (L.) Sch. Bip.	Marguerite Daisy	Flowers edible	Rop et al. (2012)
<i>Artemisia absinthium</i> L.	Wormwood	Flowering tops used to counter grassiness of goose and duck dishes	Uphof (1968), Grieve (1971), Facciola (1990)
<i>Artemisia ludoviciana</i> Nutt.	Prairie Sage, White Sage, Gray Sage, White Sagebrush, Mountain Sage	The flower heads can be used as seasoning or to make a tea	Dean (2007–2012s)
<i>Artemisia vulgaris</i> L.	Mugwort	Flowering tops added to beer or steeped into tea	Fernaldet al. (1958), Grieve (1971), Facciola (1990)
<i>Aster kantoensis</i> Kitam.	Kawara-Nogiku (Japanese)	Flowers eaten	Kunkel (1984)
<i>Aster koraiensis</i> Nakai	Korean Starwort	Flowers eaten	Kunkel (1984)
<i>Balsamorhiza deltoidea</i> Nutt.	Puget Balsam Root, Deltoid Balsam Root	Flower stalk eaten as cooked vegetables	Dean (2007–2012s)
<i>Balsamita major</i> Desf. = <i>Tanacetum balsamita</i> L.	Costmary, Bible-Leaf, Alecost, Balsam Herb, Bible Leaf, Mint Geranium	Flower petals used for conserve	Grieve (1971), Larkcom (1980), Facciola (1990)
<i>Balsamorhiza sagittata</i> (Pursh) Nutt.	Arrowleaf Balsam Root, Oregon Sunflower	Young immature flower stalks peeled and inner pith eaten	Hedrick (1972), Facciola (1990)
<i>Bellis perennis</i> L.	Common Daisy, Common Lawn Daisy, Daisy, English Daisy, European Daisy, True Daisy, Bruisewort	Flowers eaten with lettuce or greens, salad, crystallized or petals garnish on cakes. Flower and petals eaten in salads, flower buds eaten in sandwiches, soups and salads, preserved in vinegar used as substitute for capers	Hedrick (1972), Cribb and Cribb (1987), Larkcom (1980), Facciola (1990), Barash (1997), Lauderdale and Evans (1999), Newman and O'Connor (2009)

<i>Berlandiera lyrata</i> Benth.	Chocolate Daisy, Chocolate Flower, Lyreleaf Greeneyes, Green-Eyed Lyre Leaf	Flowers used for seasoning foods	Yanovsky (1936), Facciola (1990)
<i>Bidens alba</i> (L.) DC.	Spanish Needles, Beggar's Tick, Butterfly Needles, Harry Beggarticks	Blossoms excellent for salad, they hold their flavour while cooking and can be added to a variety of dishes	Deane (2007–2012d)
<i>Bidens bigelovii</i> A. Gray	Bigelow's Beggarticks	Infusion of flowering tops used as beverage in Texas	Yanovsky (1936)
<i>Calendula arvensis</i> (Vaill.) L.	Field Marigold	Flower heads pickled	Kunkel (1984), Facciola (1990)
<i>Calendula officinalis</i> L.	Calendula, Pot Marigold, English Marigold, Poet's Marigold	Flowers used in salad, soup, butter, sauce, drinks, cookie; fresh petals are chopped and added to salads. The dried petals have a more concentrated flavour and are used as a seasoning in soups, cakes, omelette, curry, custard, etc. An edible yellow dye is obtained from the petals and used as a saffron substitute to colour and flavour rice, soups, stews, cheese, cakes, puddings	Organ (1960), Uphof (1968), Facciola (1990), Garland (1993), Barash (1997), Lauderdale and Evans (1999), Roberts (2000), Lust (2001), Newman and O'Connor (2009), Micek and Rop (2011)
<i>Carduus nutans</i> L.	Musk Thistle, Nodding Thistle	Pith of flowering stem, boiled, salted and dressed. Dried flowers used in some countries as rennet to curdle milk	Fernald et al. (1958), Facciola (1990)
<i>Carlina acanthifolia</i> All.	Carlina Thistle	Flowering head cooked; used as a globe artichoke substitute	Hedrick (1972), Tanaka (1976), Kunkel (1984), Facciola (1990)
<i>Carlina acaulis</i> L.	Stemless Carlina Thistle	Flowers used as above	Kunkel (1984), Facciola (1990)
<i>Carlina vulgaris</i> L.	Carlina Thistle	Flowers used as above	Hedrick (1972), Tanaka (1976), Kunkel (1984), Facciola (1990)
<i>Carthamus tinctorius</i> L.	Safflower, Dyer's Saffron False Saffron	Bitter flower petals used as saffron substitute for colouring bread, butter and liqueurs and also used in herbal tea	Yanovsky (1936), Uphof (1968), Grieve (1971), Tanaka (1976), Facciola (1990), Hu (2005), Newman and O'Connor (2009)
<i>Centaurea cyanus</i> L.	Cornflower, Bachelor's Button, Bluebottle, Boutonniere Flower, Hurtstickle, Cyani Flower	Flowers edible raw or cooked. The fresh florets can be used in salads, as a vegetable or a garnish. An edible blue dye is obtained from the flowers, used for colouring sugar, gelatin and confections. Flowers are ideal for mixing with other flowers to make attractive confetti for sprinkling over salads, omelettes and pasta dishes	Facciola (1990), Bown (1995), Lauderdale and Evans (1999), Roberts (2000), Newman and O'Connor (2009), Rop et al. (2012), Anonymous (2012a)

Table 1 (continued)

Scientific name	English/common vernacular name	Flower edible uses	References
<i>Centaurea nigra</i> L.	Black Knapweed, Lesser Knapweed, Common Knapweed	Flower petals eaten raw, added to salads	Facciola (1990)
<i>Chamaemelum nobile</i> (L.) All.	Roman Chamomile, Chamomile, Garden Chamomile, Ground Apple, Low Chamomile	Fresh or dried flowers used to flavour sherry in Spain, used in herbal tea	Grieve (1971), Garland (1993), Barash (1997), Facciola (1990), Lauderdale and Evans (1999), Newman and O'Connor (2009)
<i>Chamomilla aurea</i> J. Gray = <i>Matricaria aurea</i> (Loefl.) Sch. Bip.	Golden Chamomile, Hungarian Chamomile	Dried flower heads brewed into an aromatic tea, also used for flavouring fine liqueurs of the French types viz. Benedictine and D.O.M., a source of essential oil for food industry	Uphof (1968), Morton (1976), Facciola (1990)
<i>Chamomilla recutita</i> (L.) Rauschert = <i>Matricaria chamomilla</i> L.	German Chamomile, Camomile, Scented Mayweed, Wild Chamomile, Hungarian Chamomile	Flowers used in herbal teas	Garland (1993), Burnie and Fenton-Smith (1996)
<i>Chrysanthemum coronarium</i> L.	Garland Chrysanthemum, Chrysanthemum Coronarium Greens, Edible Chrysanthemum Coronarium, Chop-Suey Greens, Crown Daisy	Flowers petals are used fresh, blanched briefly and added to salads, soups or pickles and eaten with fish, or dried and used in teas. A fragrant pickle known as 'kikumi' is made from the petals in Japan	Harrington (1974), Tanaka (1976), Facciola (1990), Dasuki and van den Bergh (1994), Lauderdale and Evans (1999), Woodward (2000), Roberts (2000), Newman and O'Connor (2009)
<i>Chrysanthemum frutescens</i> L. = <i>Argyranthemum frutescens</i> (L.) Sch. Bip.	Marguerite Daisy	Flowers edible	Rop et al. (2012)
<i>Chrysanthemum indicum</i> L.	Mother Chrysanthemum, Mother Daisy, Winter Aster, Ground Apple, Whig Plant; Manzanilla (Spanish)	Flower heads pickled in vinegar	Tanaka (1976), Facciola (1990)
<i>Chrysanthemum leucanthum</i> L. = <i>Chrysanthemum vulgare</i> (Vail.) Lam.	Oxeye Daisy	Unopened flowers can be marinated and used like capers. They are also used in salad and as condiment with fish or stuffed in a chicken breast	Newman and O'Connor (2009), Anonymous (2012c)
<i>Chrysanthemum morifolium</i> Ramat.	Chrysanthemum, Florist Chrysanthemum, Hardy Garden Mum	Edible leaves and flower heads boiled served as salads with fish and tofu and seasoned with vinegar and soy sauce. Flowers also prepared as tempura, pickled, dried or added to soups. Flower petals brewed into 'tangu', an aromatic tea	Tanaka (1976), Clarke (1977), Facciola (1990), Lauderdale and Evans (1999)
<i>Chrysanthemum parthenium</i> (L.) Pers. = <i>Tanacetum parthenium</i> (L.) Sch. Bip.	Feverfew	Flowers edible	Rop et al. (2012)

<i>Chrysanthemum sinense</i> Sabine = <i>Chrysanthemum morifolium</i> Ramat.	See <i>Chrysanthemum morifolium</i>	In China leaves and flowers eaten in soups	Read (1946)
<i>Chrysanthemum spatiosum</i> L.H. Bailey = <i>Chrysanthemum coronarium</i> L.	See <i>Chrysanthemum coronarium</i>	Used as for Florist <i>Chrysanthemum</i>	Facciola (1990), Dasuki and van den Bergh (1994), Woodward (2000)
<i>Chrysanthamnus confinis</i> Greene = <i>Ericameria nauseosa</i> subsp. <i>consimilis</i> (Greene) G.L. Nesom and G.I. Baird	Douglas Rabbitbrush	Flower buds eaten with salt in New Mexico	Yanovsky (1936)
<i>Cichorium intybus</i> L.	Chicory, Raddichio, Endive, Succory	Blue flowers crystallized and used to decorate cakes and puddings; flowers can be used in salads, fresh or pickled. The fresh flowers have a mild lettuce flavour and make a decorative addition to salads, while flower buds can be pickled. Picked blooms look attractive frozen in ice cubes and added to drinks	Fernald et al. (1958), Larkcom (1980), Facciola (1990), Burnie and Fenton-Smith (1996), Lauderdale and Evans (1999), Roberts (2000), McCullough (2007), Newman and O'Connor (2009)
<i>Cirsium arvense</i> (L.) Scop	Canadian Thistle	Flower stalk boiled and eaten as vegetables	Uphof (1968), Launert (1981), Facciola (1990)
<i>Cirsium eriophorum</i> (L.) Scop.	Woolly Thistle	Flower buds cooked used as a globe artichoke substitute	Hedrick (1972), Kunkel (1984), Facciola (1990)
<i>Cirsium oligophyllum</i> (Franch. & Sav.) Matsum.	Nohara Azami (Japanese)	The flower heads are fried or used in salads	Facciola (1990)
<i>Cirsium palustre</i> (L.) Coss.ex Scop.	Marsh Thistle, European Swamp Thistle	Flower stalks eaten in salad or boiled as vegetables	Fernald et al. (1958), Griewe (1971), Harrington (1974), Facciola (1990)
<i>Cirsium tanakae</i> (Franch. & Sav.) Matsum. = <i>Cirsium oligophyllum</i> (Franch. & Sav.) Matsum.	Nohara Azami (Japanese)	Flower heads fried or used in salad in East Asia	Tanaka (1976), Facciola (1990)
<i>Cirsium vulgare</i> (Savi.) Ten.	Spear Thistle, Common Thistle	Unopened flower heads eaten, receptacle cooked and served like artichoke, young flower stalks eaten, dried flower used as substitute for rennet in curdling milk for cheese making	Fernald et al. (1958), Harrington (1974), Clarke (1977), Kunkel (1984), Cribb and Cribb (1987), Facciola (1990)
<i>Cnicus benedictus</i> L.	Blessed Thistle	Flower heads, harvested before the flowers open, have been used as a globe artichoke substitute	Stuart (1987)
<i>Cosmos bipinnatus</i> Cav.	Garden Cosmos, Mexican Aster	Petals source of carotenoids for the food industry	Tinoi et al. (2006)

Table 1 (continued)

Scientific name	English/common vernacular name	Flower edible uses	References
<i>Cosmos sulphureus</i> Cav.	Cosmos, Sulphur Cosmos, Yellow Cosmos, Orange Cosmos, Klondike Cosmos	Flowers used in salad	Kaisoon et al. (2011, 2012)
<i>Crotalaria juncea</i> L.	Brown Hemp, Indian Hemp, Sunn Hemp; O-Hawaii Maton (Manipur)	Young shoots and inflorescences eaten in Manipur India	Yunnum and Tripathi (2012)
<i>Cynara cardunculus</i> L.	Cardoon, Artichoke Thistle, Cardone, Cardoni, Carduni, Cardi	Flower bases steamed, cooked; fleshy receptacle of unopened flower head, dried flowers used as substitute for rennet in making Serra cheese in Portugal. Some dishes included pickled artichokes, artichoke with mint and yoghurt, artichoke dip	Hedrick (1972), Cribb and Cribb (1987), Low (1989), Facciola (1990), Van den Bergh (1994a, b), Roberts (2000), Newman and O'Connor (2009)
<i>Cynara humilis</i> L.	Wild Artichoke, Artichoke Thistle; Alcachofra-Brava (Portuguese); Alcachofa, Alcachofa De Campo (Spanish)	Flower receptacle used in preparation of a popular tangine stew. In Morocco, the dreid flowers used as rennet in coagulating rape, a kind of sweetened junket	Wolfert (1973), Facciola (1990)
<i>Cynara scolymus</i> L. = <i>Cynara cardunculus</i> subsp. <i>flavescens</i> Wiklund	Globe Artichoke, Bur Artichoke, Artichoke Thistle	Flower buds steamed, basal fleshy portion of phyllaries (involucral bracts) of the capitula and young receptacle used as vegetables. Fleshy receptacle of unopened flower head used as substitute for rennet	Van den Bergh (1994a, b), Low (1989), Hu (2005)
<i>Dahlia juarezii</i> Van der Berg = <i>Dahlia coccinea</i> Cav.	Dahlia, Cactus Dahalia, Single-Flowered Dahlia	Flowers used in salads, cream, cheese, dahlia dip, sundried tomato and dahlia bread	Roberts (2000)
<i>Dahlia pinnata</i> Cav.	Dahlia, Garden Dahlia	The flower petals are used in salads	Kunkel (1984), Facciola (1990)
<i>Dahlia rosea</i> Cav. = <i>Dahlia pinnata</i> Cav.	See <i>Dahlia pinnata</i>	Flowers used in salads, cream, cheese and dahlia dip, sundried tomato and dahlia bread	Hedrick (1972), Roberts (2000)
<i>Dahlia</i> spp.	Dahlia	Used as above	Roberts (2000)
<i>Dendranthema grandiflorum</i> (Ramat.) Kitam.	Chrysanthemum, Garden Mum, Hardy Mum, Cushion Mum	The flower heads or petals are parboiled and served as a salad with tofu and seasoned with vinegar or soya sauce. They can also be prepared as tempura, pickled, dried or added to soups	Read (1946), Uphof (1968), Facciola (1990), Newman and O'Connor (2009)
<i>Dendranthema indicum</i> (L.) Des Moul.	Chrysanthemum, Winteraster	The flower heads are pickled in vinegar	Uphof (1968), Kunkel (1984), Facciola (1990)
<i>Dendranthema vestitum</i> (Hemsl.) Ling = <i>Chrysanthemum vestitum</i> (Hemsl.) Stapf.	Ju-Hua (Chinese)	Dried flowers used in herbal teas	Hu (2005)

<i>Dendranthema morifolium</i> (Ramat.) Tzvel.	Florists Chrysanthemum, Hardy Garden Mum; Ju Hau (Chinese)	Ligulate florets used for special Chinese delicacy, dried florets used for chrysanthemum tea, in Korea rice wine flavoured with chrysanthemum flowers is called 'gukwaju', florets mix with a thick snake meat soup	Hu (2005), Wikipedia (2012)
<i>Dicoria brandegeei</i> A. Gray = <i>Dicoria canescens</i> A. Gray	Desert Twinbugs	Flowers and seeds ground for food in Arizona	Yanovsky (1936)
<i>Echinacea purpurea</i> (L.) Moench	Eastern Purple Coneflower, Purple Coneflower, Echinacea, Snakeroot	Some dishes include Echinacea Pane bagnò (bathed bread) decorated with fresh echinacea petals and a wedge of lemon; American Indian savoury Echinacea spread, Echinacea and melon fruit salad	Roberts (2000)
<i>Emilia sonchifolia</i> (L.) DC.ex DC.	Lilac Tasseflower, Red Tassel Flower, Cupid's Shaving Brush, Emilia, Purple Sow Thistle, Flora's Paintbrush	The whole plant, including the unopened flowers, can be eaten raw or cooked	Cribb and Cribb (1987)
<i>Erechtites hieracifolia</i> (L.) Raf.	American Burnweed, Fireweed, Pilewort	Young inflorescence head, flowering top eaten raw or steamed and served with rice	Rifai (1994)
<i>Erechtites valerianifolia</i> (Link ex Wolf) Less ex DC.	Brazilian Fireweed, Tropical Burnweed, Ceylon Thistle, Fireweed, Fireweed Daisy	Young inflorescence head, flowering top eaten raw or steamed and served with rice	Burkill (1966), Ochse and van den Brink (1980), Cribb and Cribb (1987), Facciola (1990), Rifai (1994)
<i>Galacites tomentosa</i> Moench	Purple Milk Thistle	Tender flower stalk eaten	Hedrick (1972), Facciola (1990)
<i>Galinsoga parviflora</i> Cav.	Gallant Soldier, Potato Weed, Yellow Weed, Galinsoga	The leaves, stem and flowering shoots eaten raw or cooked and eaten as a potherb, or added to soups and stews	Fernald et al. (1958), Harrington (1974), Cribb and Cribb (1987), Facciola (1990), Elias and Dykeman (2009)
<i>Gundelia tournefortii</i> L.	Galgol, Tumbleweed, Tumble Thistle	The thick flowering stem, with the young and still undeveloped flower buds, is sold in the local markets in Jerusalem. It is a sought after vegetable, cooked like globe artichokes	Hedrick (1972), Kunkel (1984), Wright (2001)
<i>Gynura nepalensis</i> DC.	Cholesterol Spinach; Tera Paibi (Manipur)	Young shoots and inflorescences are eaten	Yumnum and Tripathi (2012)
<i>Helianthus annuus</i> L.	Common Sunflower, Sunflower, Mirasol	Young flower buds are steamed and served like globe artichokes with butter and vinegar; petals of openend flowers can be used	Hedrick (1972), Harrington (1974), Facciola (1990), Garland (1993), Barash (1997), Lauderdale and Evans (1999), Roberts (2000)
<i>Helianthus tuberosus</i> L.	Jerusalem Artichoke, Sunroot, Sunchoke, Earth Apple, Topinambour	Flower reported edible	King (2007)

Table 1 (continued)

Scientific name	English/common vernacular name	Flower edible uses	References
Betulaceae			
<i>Alnus oregona</i>	Oregon Alder	Catkins eaten raw or cooked have a bitter flavour; added to soups, dried and powdered as a spice, or nibbled raw	Schofield (2003)
<i>Alnus rhombifolia</i> Nutt.	White Alder	Flowers used as above	Schofield (2003)
<i>Alnus rubra</i> Ong.	Red Alder	Flowers used as above	Schofield (2003)
<i>Alnus sinuata</i> (Regel.) Rydb.	Sitka Alder	Flowers used as above	Schofield (2003)
<i>Alnus tenuifolia</i> Nutt.	Mountain Alder	Flowers used as above	Schofield (2003)
<i>Alnus viridis crispa</i> (Aiton.) Turrill.	American Green Alder	Flowers used as above	Schofield (2003)
<i>Betula glandulosa</i> Michx.	Scrub Birch	Flowers used as above	Schofield (2003)
<i>Betula kenaica</i> W.H. Evans	Kenai Birch	Flowers used as above	Schofield (2003)
<i>Betula nana</i> L.	Dwarf Birch	Flowers used as above	Schofield (2003)
<i>Betula occidentalis</i> Hook.	Water Birch	Flowers used as above	Schofield (2003)
<i>Betula papyrifera</i> Marshall	Paper Birch	Flowers used as above	Schofield (2003), Facciola (1990)
<i>Betula pendula</i> Roth.	Silver Birch	Young catkins eaten	Bryan and Castle (1975), Schofield (2003)
<i>Betula pubescens</i> Ehrh.	White Birch	Young catkins eaten	Bryan and Castle (1975), Schofield (2003)
Bignoniaceae			
<i>Catalpa bungei</i> C.A. Meyer	North China Catalpa; Qiu Shu (Chinese)	Unopened buds pickled, flowers stir-fried	Hu (2005)
<i>Catalpa kaempferi</i> Sieb. and Zucc. = <i>Catalpa ovata</i> G. Don	Chinese Catalpa	In China, fresh or dried flowers washed, thoroughly boiled and eaten with oil and salt	Read (1946)
<i>Catalpa ovata</i> G. Don	Chinese Catalpa	Flowers and young pods eaten cooked	Facciola (1990)
<i>Chilopsis linearis</i> (Cav.) Sweet	Desert Willow	The blossoms used for food	Moerman (1998)
<i>Dolichandrone rheedii</i> (Spreng.) Seem. = <i>Dolichandrone spathacea</i> (L.f.) Schum.	Mangrove Trumpet Tree; Thakut (Burmese)	Flowers eaten in Myanmar	Tanaka (1976)
<i>Dolichandrone serrulata</i> (Wall. DC.) Seem.	Khae Khao (Thai); Thakut (Burmese)	Flowers eaten	Wetwiyaklung et al. (2008), Maisuthisakul et al. (2008), Maisuthisakul (2012)

<i>Dolichandrone stipulata</i> (Wall.) Benth. and Hook.f. = <i>Markhamia stipulata</i> (Wall. Seem.)	Mahlwa (Burmese); Xi Nan Mao Wei Mu (Chinese)	Flowers eaten in Myanmar	Hedrick (1972), Facciola (1990)
<i>Heterophragma adenophyllum</i> (Wall. Ex G. Don) Seem. Ex Benth. and Hook. f. = <i>Haplophragma adenophyllum</i> (Wall. Ex G. Don.) Dop	Karenwood; Khae Khon (Thai)	Flowers, young fruit, slightly bitter, cooked as vegetables	Pongpangan and Poobarasert (1985)
<i>Markhamia stipulata</i> (Wall.) Seem. ex K. Schum.	Khae Hang Kang (Thai)	Flowers, young fruit cooked as vegetables	Pongpangan and Poobarasert (1985)
<i>Millingtonia hortensis</i> L.f.	Indian Cork Tree, Tree Jasmine	Flowers edible	Wongwattanasathien et al. (2010)
<i>Oroxylum indicum</i> (L.) Kurz.	Broken Bones Plant, Indian Trumpet Flower, Midday Marvel, Tree of Damocles; Kotodu, Boongli (Assamese)	In Andhra Pradesh and Assam, the flowers are cooked and eaten as vegetables. In Java, the young leaves, flowers and the bark of the trunk are eaten uncooked with rice usually prepared as 'sambal pepoh'	Ochse and van den Brink (1980), Patiri and Borah (2007), Reddy et al. (2007), Medhi and Borthakur (2012)
<i>Spathodea campanulata</i> Beauv.	African Tulip Tree, Fire Bell	Flowers eaten in Thailand	Wetiyaklung et al. (2008)
Bixaceae			
<i>Cochlospermum fraseri</i> Planch.	Kapok Bush	Flowers eaten in salad	Low (1991)
Boraginaceae			
<i>Anchusa azurea</i> Mill.	Anchusa, Italian Bugloss, Alkanet, Wild Bugloss	Flowers eaten raw. make an excellent and decorative addition to the salad bowl, or used as a garnish	Larkcom (1980), Facciola (1990)
<i>Anchusa capensis</i> Thunb.	Cape Forget-Me-Not	Prized blue flowers eaten in salads, including seafood, fruit, potato, vegetable and tossed green salads, also used in cold drinks, pasta, puddings, custards, icing and hot and cold soups	Kunkel (1984), Facciola (1990)
<i>Anchusa officinalis</i> L.	Alkanet, Common Bugloss, Common Alkanet, Common Anchusa, Alkanet, Bee Bread, Ox's Tongue, Starflower, Common Borage, Orchanet, Spanish Bugloss, Enchusa, Lingua Bovina, Blue Bugloss	Flowers eaten raw. An excellent and decorative addition to the salad bowl, or used as a garnish	Facciola (1990)

(continued)

Table 1 (continued)

Scientific name	English/common vernacular name	Flower edible uses	References
<i>Borago officinalis</i> L.	Borage, Starflower	Flowers used in vegetable and fruit salads or used to garnish soups or to decorate desserts, cakes and pudding. Flowers impart flavour to summer fruit drinks (punch, compote), beer, cider and wine. Flower petals used to colour vinegar blue. Flowers make an excellent choice for freezing in ice cubes and floating on iced tea. Petals have a cucumber taste and the stamens add a hint of sweetness	Hedrick (1972), Launert (1981), Chiej (1984), Facciola (1990), Garland (1993), Barash (1997), Lauderdale and Evans (1999), Roberts (2000), Newman and O'Connor (2009)
<i>Cordia dichotoma</i> G. Forst.	Fragrant Manjack, Snotty Gobbles, Glue Berry, Pink Pearl, Bird Lime Tree, Indian Cherry, Clammy Cherry	Flowers are eaten	Cribb and Cribb (1987), Tanaka (1976), Facciola (1990)
<i>Cordia myxa</i> L.	Assyrian Plum, Sebasten, Large Sebasten, Lasora (Hindi), Uddhala (Tamil), Sleshmataka (Sanskrit)	Flowers eaten as vegetables	Dalziel (1937), Hedrick (1972), Facciola (1990)
<i>Echium vulgare</i> L.	Blue Devil, Blue Echium, Blue Thistle, Blue Weed, Blueweed, Common Viper's Bugloss, Common Vipersbugloss, Viper's Bugloss	Flowers are candied and added to salads	Deane (2007–2012t)
<i>Mertensia bella</i> Piper	Beautiful Bluebells, Oregon Lungwort	Flowers eaten raw as snacks or added to salad	Schofield (2003)
<i>Mertensia ciliata</i> (James ex Torr.) G. Don	Mountain Bell, Tall Fringed Bluebells, Streamside Bluebells	Flowers used as above	Schofield (2003), Wikipedia (2012)
<i>Mertensia longiflora</i> Greene	Mall Bluebells, Long Bluebells	Flowers used as above	Schofield (2003)
<i>Mertensia maritima</i> (L.) Gray	Oysterleaf, Oysterplant, Sea Bluebells	Flowers used as above	Schofield (2003)
<i>Mertensia oblongifolia</i> (Nutt.) G. Don = <i>Cerinthodes oblongifolia</i> (Nutt.) Kuntze	Oblongleaf Bluebells, Sagebrush Bluebells	Flowers used as above	Schofield (2003)
<i>Mertensia paniculata</i> (Aiton) G. Don = <i>Cerinthodes paniculatum</i> Kuntze	Tall Lungwort, Tall Bluebell	Flowers used as above	Schofield (2003)
<i>Myosotis sylvatica</i> Ehrh. ex Hoffm.	Forget-Me-Not, Wood Forget-Me-Not	Blossoms are added to salads, used as a garnish, and make excellent candied blossoms	Deane (2007–2012o)
<i>Pentaglottis sempervirens</i> (L.) Tausch.	Evergreen Alkanet, Green Alkanet, Evergreen Bugloss, Alkanet	Flowers edible raw, have a mild flavour and mucilaginous texture and are mainly used as an ornament in fruit drinks and salads	Larkcom (1980), Launert (1981), Facciola (1990)

Brassicaceae			
<i>Alliaria petiolata</i> (M. Bieb.) Cavara and Grande	Garlic Mustard	Flowers eaten raw	Elias and Dykeman (2009)
<i>Arabis alpina</i> L.	Alpine Rock Cress	Flowers eaten raw or cooked and have a cress-like flavour	Tanaka (1976), Kunkel (1984), Facciola (1990), Deane (2007–2012u, x)
<i>Arabis lyrata</i> L. = <i>Arabidopsis lyrata</i> (L.) O'Kane and Al-Shehbaz	Kamchatka Rockcress	Buds are used as salad garnish or boiled in water and served with butter and parmesan cheese	Schofield (2003)
<i>Argula</i> sp.	Rocket, Roquette	Light yellow flowers are sprinkled on salads or put afloat in soups to add a bit of pepper	Deane (2007–2012d)
<i>Armoracia rusticana</i> P. Gaertn., B. Mey. and Scherb.	Horseradish	Flowers edible sprinkle onto salad	Deane (2007–2012p)
<i>Barbarea orthoceras</i> Ledeb.	American Yellowrocket, American Wintercress	Flower buds used as salad garnish or boiled and eaten with butter and parmesan cheese	Schofield (2003)
<i>Barbarea vulgaris</i> R. Br.	Bittercress, Yellow Rocketcress	Flowering stems are harvested before the flowers open and cooked like broccoli	Fernald et al. (1958), Facciola (1990)
<i>Brassica alboglabra</i> L.H. Bailey = <i>Brassica oleracea</i> (Alboglabra Group); <i>Brassica oleracea</i> L. cv. group Chinese Kale	Chinese Kale, Kai Lan	Open and unopened flowers, stalks and shoots eaten	Larkcom (1980), Sagwansupyakom (1994), Woodward (2000)
<i>Brassica campestris</i> L. = <i>Brassica rapa</i> L.	Field Mustard; Hangan (Manipur)	In Northeast India, the flowers are a delicacy; they are used to make a vegetable soup. The flowers are cleaned and boiled without any herbs, not even salt, and the soup is consumed in a mug along with meals. It is slightly bitter	Hauzel (2012)
<i>Brassica carinata</i> A. Braun	Abyssinian Cabbage	Immature flowering stems cooked; used like broccoli	Larkcom (1980), Facciola (1990)
<i>Brassica chinensis</i> L. = <i>Brassica rapa</i> L. cv. group Pak Choi	Chinese Cabbage, Pak Choi	Flowers eaten	Larkcom (1980), Tay and Toxopeus (1994)
<i>Brassica cretica</i> Lam. = <i>Brassica oleracea</i> var. <i>botrytis</i> L., <i>Brassica oleracea</i> L. cv. group Cauliflower	Cauliflower	Immature flowering head eaten raw or cooked	Uphof (1968), Simons (1975), Hu (2005), Newman and O'Connor (2009)
<i>Brassica juncea</i> var. <i>crispifolia</i> L.H. Bailey = <i>Brassica juncea</i> subsp. <i>juncea</i>	Curled Mustard	Flowers and young flowering stems eaten raw or cooked	Larkcom (1980)
<i>Brassica juncea</i> var. <i>foliosa</i> L.H. Bailey = <i>Brassica juncea</i> subsp. <i>juncea</i>	Plain-Leaved Mustard; Da Wang Jie (Chinese); Setsuriko (Japanese)	Flowers used as above	Larkcom (1980)

(continued)

Table 1 (continued)

Scientific name	English/common vernacular name	Flower edible uses	References
<i>Brassica juncea</i> var. <i>multiceps</i> N. Tsen and S.N. Lee = <i>Brassica juncea</i> subsp. <i>juncea</i>	Nine-Headed Mustard, Red in Snow, Serrated-Leaved Mustard, Multishoot Mustard	Flowers used as above	Larkcom (1980)
<i>Brassica juncea</i> var. <i>napiiformis</i> (Paillieux & Bois) Kitam = <i>Brassica juncea</i> subsp. <i>juncea</i>	Turnip-Rooted Mustard	Flowers used as above	Larkcom (1980)
<i>Brassica juncea</i> var. <i>tumida</i> N. Tsen and S.N. Lee = <i>Brassica juncea</i> L. Czern	Sichuan Pickled Mustard, Sichuan Swollen Stem Mustard, Big Stem Mustard, Yangtze River Mustard	Flowers used as above	Larkcom (1980)
<i>Brassica juncea</i> (L.) Czern.	Brown Mustard	Flowers used as above	Larkcom (1980)
<i>Brassica juncea</i> var. <i>rugosa</i> (Roxb.) Kitam. = <i>Brassica juncea</i> subsp. <i>juncea</i>	Cabbage Leaf Mustard, Heading Leaf Mustard, Broad-Leaved Mustard, Swatow Mustard	Flowers used as above	Larkcom (1980)
<i>Brassica napus</i> L.	Rape, Oilseed Rape	Inflorescences used like broccoli	Uphof (1968), Tanaka (1976), Facciola (1990)
<i>Brassica nigra</i> (L.) K. Koch	Black Mustard	Young flower clusters used like broccoli	Uphof (1968), Grieve (1971), Facciola (1990)
<i>Brassica oleracea</i> (Acephala Group) = <i>Brassica oleracea</i> L. cv. group Kale	Kale, Collard, Flowering Kale	Unopened flower clusters called broccolini used like broccoli	Facciola (1990), Kraft and Kraft (1977)
<i>Brassica oleracea</i> (Alboglabra Group) = <i>Brassica oleracea</i> L. cv. group Chinese Kale	Chinese Broccoli, Chinese Kale, Kai Lan	Leaves, flowers, flower stalks and young inflorescences steamed, stir-fried, cooked with oyster sauce or used in 'sukiyaki'. Florets cut from stems dipped in tempura batter and deep fried	Herklots (1972), Tanaka (1976), Kraft and Kraft (1977), Facciola (1990), Larkcom (1991), Sagwansupyakorn (1994)
<i>Brassica oleracea</i> (Botrytis Group) = <i>Brassica oleracea</i> L. cv. group Cauliflower	Cauliflower; Kobi Yhamchet (Manipur)	Immature flower heads eaten raw in salads, boiled, steamed, braised, fried, used in soups and casseroles and prepared as tempura, etc.; flower stalks make excellent eating, made into soups	Tanaka (1976), Larkcom (1980), Facciola (1990), Van der Vossen (1994), Newman and O'Connor (2009), Yunnum and Tripathi (2012)
<i>Brassica oleracea</i> (Italica Group) = <i>Brassica oleracea</i> L. cv. group Broccoli	Broccoli, Cape Broccoli, Sprouting Broccoli	Immature flower heads eaten raw in salads, boiled, steamed, sauteed, prepared as tempura, marinated, serve as au gratin or with a cream sauce	Facciola (1990), Van der Vossen (1994), Lauderdale and Evans (1999), Newman and O'Connor (2009)
<i>Brassica oleracea</i> var. <i>palmifolia</i> DC. = <i>Brassica oleracea</i> (Palmifolia Group)	Jersey Kale	Young flowering shoots eaten raw or cooked	Fern (1992–2003)

<i>Brassica oleracea</i> var. <i>asparagoides</i> DC. = <i>Brassica oleracea</i> L.	Nine-Star Perennial Broccoli	Flowering shoots used as above	Fern (1992–2003)
<i>Brassica oleracea</i> var. <i>italica</i> Plenck = <i>Brassica oleracea</i> (Italica Group), <i>Brassica oleracea</i> L. cv. group Broccoli	Broccoli, Calabrese; Ye-Hua (Chinese)	As for broccoli	Van der Vossen (1994), Hu (2005), Newman and O'Connor (2009)
<i>Brassica oleracea</i> var. <i>viridis</i> L. = <i>Brassica oleracea</i> (Viridis Group)	Collards, Cow Cabbage, Kale, Tall Kale, Tree Kale, Fodder Kale	Young flowering shoots eaten raw or cooked	Fern (1992–2003)
<i>Brassica parachinensis</i> Bailey = <i>B. rapa</i> L. cv. group Caisin	Caisin, Choi Sum	Young flowering shoots – raw or cooked	Larkcom (1980, 1991), Opeña and Tay (1994)
<i>Brassica pekinensis</i> (Lour.) Rupr. = <i>Brassica rapa</i> (Pekinensis Group), <i>Brassica rapa</i> L. cv. group Chinese Cabbage	Chinese Cabbage, Celery Cabbage, Peking Cabbage, Petsai	Young flowering shoots eaten raw or cooked	Larkcom (1980), Kuo and Toxopeus (1994)
<i>Brassica perviridis</i> (L.H. Bailey) L.H. Bailey = <i>Brassica rapa</i> (Perviridis Group)	Mustard Spinach, Komatsuna	Young flowering shoots eaten raw or cooked	Larkcom (1980, 1991)
<i>Brassica rapa</i> Ruvo Group	Broccoli Raab, Runip Broccoli, Rapini	Flowering stem and leaves pleasantly bitter taste, eaten boiled, steamed, braised, sautéed or served with pasta, potatoes, Italian sausages, etc.	Kraft and Kraft (1977), Halpin (1978), Facciola (1990)
<i>Brassica rapa</i> Sarson Group	Sarson, Toria	Flower cluster used for culinary purposes, flower stalks cooked as vegetables	Tanaka (1976), Facciola (1990)
<i>Brassica rapa</i> var. <i>parachinensis</i> (L.H. Bailey, Hanelt. = <i>Brassica rapa</i> (Caisin Group)	Choysum, Caixin, False Pakchoi	Mature inflorescence, flowers and flowering shoots and leaves eaten cooked, steamed or stir-fried	Opeña and Tay (1994)
<i>Brassica rapa</i> L.	Field Mustard, Wild Turnip, Turnip Mustard, Turnip Rape	Immature flower clusters served like broccoli	Crowhurst (1972), Tanaka (1976)
<i>Brassica rapa</i> var. <i>campestris</i> (L.) Peterm. = <i>Brassica rapa</i> L.	Oil Rape Shoot; Yoi-Cai-Tia (Chinese)	Flowering shoots eaten	Hu (2005)
<i>Brassica rapa</i> var. <i>nippoponica</i> L.H. Bailey = <i>Brassica rapa</i> (Nippoponica Group)	Potherb Mustard, Mibuna Salad Green, Kyoto Salad Green Japanese Salad Green; Mizuna, Mibuna (Japanese)	Immature flowering shoots and leaves cooked like broccoli	Larkcom (1980, 1991)

(continued)

Table 1 (continued)

Scientific name	English/common vernacular name	Flower edible uses	References
<i>Brassica rapa</i> var. <i>parachinensis</i> (L.H. Bailey) Hanelt = <i>Brassica rapa</i> (Caisin Group)	False Pak Choi, Choysum, Caixin, Caisin	Immature flowering shoots and leaves cooked like broccoli	Larkcom (1980, 1991), Woodward (2000), Hu (2005)
<i>Brassica rapa</i> var. <i>purpurea</i> (L.H. Bailey) Kitam. = <i>Brassica rapa</i> L.	Red Oil Rape, Purple-Stem Mustard; Hon Tsai Tai (Chinese)	Flowering shoots and leaves eaten	Larkcom (1991), Hu (2005)
<i>Brassica rapa</i> var. <i>rosularis</i> (Tsen & Lee) Hanelt = <i>Brassica rapa</i> L. subsp. <i>chinensis</i> (L.) Hanelt	Flat Cabbage, Flat Pak Choi, Rosette Pakchoi, Spoon Mustard, Tatsoi	Flowering shoots and leaves eaten	Larkcom (1991)
<i>Brassica</i> spp.	Wild Mustard	Flower buds used as salad garnish or boiled and eaten with butter and parmesan cheese	Schofield (2003), Newman and O'Connor (2009)
<i>Bunias orientalis</i> L.	Turkish Warty Cabbage, Turkish Rocket, Hill Mustard	Flower buds and flowering stems eaten raw or cooked	Phillips and Rix (1998)
<i>Cakile edentula</i> (Bigelow) Hook.	American Sea Rocket	Flower buds combined with milder greens used as potherb	Fernad et al. (1958), Facciola (1990)
<i>Cakile maritima</i> Scop.	Sea Rocket, European Seacroket	Leaves, stems, flower buds and immature seedpods eaten raw or cooked	Grieve (1971), Hedrick (1972), Facciola (1990)
<i>Cardamine heptaphylla</i> (Vill.) O.E. Schulz.	Seven-Leaf Toothwort, Pinnate Coral Root	Flowers eaten raw	Fern (1992–2003)
<i>Cardamine hirsuta</i> L.	Hairy Bittercress, Nursery Weed, Common Bitter Cress, Splitting Jenny, Flickweed	Leaves and flowers eaten raw or cooked, mainly used as a garnish or flavouring in salads etc., but are also sometimes used as a potherb	Hedrick (1972), Tanaka (1976), Larkcom (1980), Facciola (1990)
<i>Cardamine kitaibelii</i> Bech.	Kitaibel's Bittercress	Flowers eaten raw	Fern (1992–2003)
<i>Cardamine pentaphyllos</i> (L.) Crantz	Showy Toothwort	Flowers eaten raw	Fern (1992–2003)
<i>Cardamine pratensis</i> L.	Lady's Smock, Cuckoo Flower	Flowers and flower buds with a pungent cress-like flavour eaten raw as a pleasant nibble and also add a delicious flavour to salads	Facciola (1990), Fern (1992–2003)
<i>Cochlearia anglica</i> L.	English Scurvy Grass	Flower heads eaten raw in salads and sandwiches	Facciola (1990)
<i>Crambe maritima</i> L.	Sea Kale	The flowering shoots used like sprouting broccoli; they are quite nice raw and delicious when lightly steamed	Fern (1992–2003)
<i>Crambe orientalis</i> L.	Oriental Sea Kale	Flower stalks prepared like broccoli	Hedrick (1972), Facciola (1990)

<i>Diplotaxis muralis</i> (L.) DC.	Annual Wall Rocket, Stinking Wall-Rocket, Stink-Weed, Cross-Weed, Sand-Rocket, Wall-Mustard	The flowers and the leaves have a spicy, peppery flavour and are delicious added to a salad and rice or sprinkled over cooked French beans. Whole flowers added to 'taramasalata' and serve with brown toast	Anonymous (2012a)
<i>Eruca sativa</i> Mill. = <i>Eruca vesicaria</i> (L.) Cav.	Rocket Salad, Arugula, Roquette	Flowers are used as a garnish; the flowers and the leaves have a spicy, peppery flavour and are delicious added to a salad and rice or sprinkled over cooked French beans. Add whole flowers to 'taramasalata' and serve with brown toast	Kraft and Kraft (1977), Halpin (1978), Facciola (1990), Lauderdale and Evans (1999), Newman and O'Connor (2009), Anonymous (2012a)
<i>Eruca vesicaria</i> var. <i>sativa</i> (Mill.) Thell. = <i>Eruca vesicaria</i> (L.) Cav.	Rocket Arugula	Flowers eaten raw (make a nice garnish on the salad bowl)	Larkcom (1980), Facciola (1990), Lauderdale and Evans (1999)
<i>Eutrema wasabi</i> (Sieb.) Max. = <i>Eutrema japonicum</i> (Miq.) Koidz.	Japanese Horse Radish, Wasabi	Flowers soaked in salt water mixed with sake lees to make a popular pickle called 'wasabi-zuke'	Tanaka (1976), Facciola (1990)
<i>Hesperis matronalis</i> L.	Sweet Rocket, Dame's Violet	Flowers add spicy flavour to salads and fruit dishes. It combines well with chicken dishes and many fish recipes. Flowers can also be made into a flavoursome hot tea	Deane (2007–2012n), Anonymous (2012a), McVicar (2003)
<i>Lepidium densiflorum</i> Schrad.	Common Pepperweed, Prairie Peppergrass, Peppergrass	Flower buds used as salad, garnish, or boiled and eaten with butter and parmesan cheese	Schofield (2003)
<i>Lobularia maritima</i> (L.) Desv.	Sweet alyssum	Flowers can be used as flavouring herb in salads or other dishes	Facciola (1990), Deane (2007–2012o, x)
<i>Matthiola incana</i> (L.) R.Br.	Stock	Flowers eaten as a vegetable or used as salad, garnish especially with sweet desserts	Tanaka (1976), Facciola (1990)
<i>Peltaria alliacea</i> Jacq.	Garlic Cress	Flowers eaten raw; make a very tasty addition to summer salads	Fern (1992–2003)
<i>Raphanus landra</i> Moretti ex DC. = <i>Raphanus raphanistrum</i> subsp. <i>landra</i> (Moretti ex DC.) Bonnier and Layens	Radish	Flowers used as above	Fern (1992–2003)
<i>Raphanus maritimus</i> Don = <i>Raphanus raphanistrum</i> subsp. <i>landra</i> (Moretti ex DC.) Bonnier and Layens	Sea Radish	Flowers used as above	Fern (1992–2003)

(continued)

Table 1 (continued)

Scientific name	English/common vernacular name	Flower edible uses	References
<i>Raphanus raphanistrum</i> L.	Wild Radish	Flowers eaten raw, a nice addition to salads. The flower buds are lightly steamed and used as a broccoli substitute	Launert (1981)
<i>Raphanus sativus</i> L.	Radish, European Radish, Jointed Charlock; Lobak (Chinese)	Flower heads eaten as cooked vegetables. Young inflorescences and leaves serve as a vegetable or sepan Flowers add colour to the top of a salad or sprinkle over cooked vegetables to add a little spice	Tanaka (1976), Ochse and Van Den Brink (1980), Larkcom (1980), Facciola (1990), Woodward (2000), Newman and O'Connor (2009), Brown (2011)
<i>Raphanus sativus</i> var. <i>caudatus</i> (L.f) H. Vilms = <i>Raphanus sativus</i> var. <i>mougrii</i> H.W.J. Helm	Radish (English), Hatsuka Daikon (Japanese) Rat-Tail; Radish Phak Khee Huut (Thai)	In Thailand, inflorescences and young fruits are eaten with 'nam phrik' or cooked in the mixed vegetable curry, 'kaeng kae'. Flowers eaten raw, a nice spicy addition to salads	Uphof (1968), Grieve (1971), Tanaka (1976), Larkcom (1980), Facciola (1990), Jircas (2010), Anonymous (2012a)
<i>Raphanus sativus</i> var. <i>niger</i> J. Kern = <i>Raphanus sativus</i> var. <i>sativus</i>	Oriental Radish	Young flower clusters eaten raw or cooked. Flowers have a spicy flavour with a crisp pleasant texture; they make a nice addition to salads or can be used as a broccoli substitute	Launert (1981), Facciola (1990), Fern (1992–2003)
<i>Raphanus sativus</i> var. <i>oleiformis</i> Pers.	Fodder Radish	Flowers used as above	Launert (1981), Facciola (1990), Fern (1992–2003)
<i>Rhynchosinapis wrightii</i> (O.E. Schulz.) Dandy = <i>Coincya wrightii</i> (O.E. Schultz) Stace	Lundy Cabbage	Flowers and young flowering stems eaten raw or cooked	Fern (1992–2003)
<i>Sinapis arvensis</i> L.	Charlock, Wild Mustard, Wild Turnip	Young inflorescence and flowering stems—cooked. A pleasant, cabbage/radish flavour, they can be used as a broccoli substitute	Hedrick (1972), Launert (1981), Facciola (1990), Steenbeeke (2001), Komarov (2004)
<i>Sisymbrium irio</i> L.	London Rocket, Londonrocket, Rocket Mustard	Flowers eaten raw in salad	Bailey (1949), Kunkel (1984), Facciola (1990)
<i>Thlaspi arvense</i> L.	Field Pennycress	Flower buds used as salad garnish, or boiled and eaten with butter and parmesan cheese	Schofield (2003)
Bromeliaceae			
<i>Bromelia pinguin</i>	Wild Pineapple, Wild Pine, Pinguin, Bayonette	Fried inflorescence eaten in El Salvador	Uphof (1968), Williams (1981), Facciola (1990)
<i>Karatas plumieri</i> E. Morren = <i>Bromelia karatas</i> L.	Karatas, Monkey Banana, Pinguin, Pinguin, Pingwing, Plumier Pingwing, Wild Pin	Young inflorescences cooked or used with eggs	Williams (1981)
<i>Tillandsia erubescens</i> Schlecht.	Flor De Encino	Inflorescences eaten reputed to be sweet	Laferriere et al. (1991)

<i>Tillandsia recurvata</i> L.		Inflorescences eaten	Laferriere et al. (1991)
Bursaceae			
<i>Boswellia serrata</i> Roxb. ex Colebr.	Indian Olibanum Tree, Olibanum, Luban, Gond	In India, flowers and seeds eaten by the Bhils peoples	Watt (1908)
Cactaceae			
<i>Epiphyllum oxypetalum</i> (DC.) Haw.	Dutchman Pipe Cactus, Night Queen, Orchid Cactus, Jungle Cactus, Night Blooming Cereus; Tan Hua (Chinese)	Dried open flowers used for making soups	Hu (2005)
<i>Ferocactus acanthodes</i> (Lem.) Britton and Rose	Barrel Cactus	Flower buds eaten cooked	Clarke (1977), Facciola (1990)
<i>Ferocactus viridescens</i> (Nutt. ex Torr. & A. Gary) Britton and Rose	Coast Barrel Cactus	Flower buds edible	Hedrick (1972), Tate (1976), Facciola (1990)
<i>Ferocactus wislizenii</i> (Engelm.) Britton and Rose	Arizona Barrel Cactus	Flower buds eaten cooked	Hedrick (1972), Tate (1976), Facciola (1990)
<i>Hamatocactus hamatocanthus</i> (Muehlenpf.) F.M. Knuth	Turks Head, Lemon Cactus	Unopened flowers soaked overnight in water and boiled or fried	Tate (1976), Uphof (1968), Facciola (1990)
<i>Hylocereus megalanthus</i> (K. Schum. ex Vaupel) Ralf Bauer	Yellow Pitahaya, Midnight Cactus.	Flowers used as below	Lim (2012a)
<i>Hylocereus polyrhizus</i> (F.A.C. Weber) Britton and Rose = <i>Hylocereus lemairei</i> (Hook.) Britton and Rose	Red Pitaya, Red Pitahaya, Dragonfruit, Night Blooming Cereus, Strawberry Pear, Belle Of The Night, Conderella Plant	Unopened flower buds are cooked and eaten as vegetable. The flowers are harvested before anthesis and dried for subsequent use as vegetable in soups	Lim (2012a)
<i>Hylocereus undatus</i> (Haw.) Britton and Rose	Pitahaya, Dragonfruit, Night Blooming Cereus, Strawberry Pear, Belle Of The Night, Conderella Plant; Ba Wang (Chinese)	Flowers used as above vegetable in soups	Morton (1987), Facciola (1990), Hu (2005), Lim (2012a)
<i>Marshalllocerues thurberi</i> (Engelm.) Backeb. = <i>Stenocereus thurberi</i> subsp. <i>thurberi</i>	Organ Pipe Cactus	Petals are eaten in southwestern America	Yanovsky (1936), Tate (1976), Facciola (1990)
<i>Myrtillocactus geometrizans</i> (Mart. ex Pfeiff.) Console	Blue Candle, Whortleberry Cactus, Garambulla Cactus, Garambullo, Bilberry Cactus, Blue Flame, Blue Candle, Blue Myrtle Cactus	Flowers eaten raw in salads or cooked with eggs	Facciola (1990)

(continued)

Table 1 (continued)

Scientific name	English/common vernacular name	Flower edible uses	References
<i>Opuntia basilaris</i> Engelm. and J.M. Bigelow	Bakersfield Beavertail, Beavertail, Branching Beavertail, Elongated Beavertail, Kern Beavertail, Short-Joint Beavertail, Trelease Beavertail, Trelease's Beavertail, Woodbury Beavertail	Flowers and flowerbuds eaten cooked	Yanosky (1936), Facciola (1990)
<i>Opuntia ficus-indica</i> (L.) Mill.	Prickly Pear, Indian Fig, Tuna Cactus, Barbary Fig, Cactus Pear, Christian Fig,	Among all the <i>Opuntia</i> , the Prickly Pear Cactus flower is the most often eaten, not raw but cooked, usually boiled. Their flavour leans towards tart. The blossoms also make a good wine	Deane (2007–2012i), Roberts (2000)
Calycanthaceae			
<i>Chimonanthus praecox</i> (L.) Link	Wintersweet, Japanese Allspice; La Mei Hua (Chinese)	In China, the flowers are thoroughly boiled and eaten with oil and salt. The flower petals are used to flavour and scent tea	Read (1946), Tanaka (1976), Kunkel (1984), Facciola (1990)
Campanulaceae			
<i>Campanula alliarifolia</i> Willd.	Cornish Bellflower	Flowers—a pleasant taste and texture with a slight sweetness	Thomas (1977)
<i>Campanula carpatica</i> var. <i>turbinata</i> (Schott, Nyman and Kotschy) Nyman = <i>Campanula carpatica</i> Jacq.	Carpathian Bellflower, Tussock Bellflower	Flowers—raw or cooked. Slightly sweet, they make a very pleasant and decorative addition to the salad bowl[K]	Fern (1992–2003)
<i>Campanula carpatica</i> Jacq.	Carpathian Bellflower, Tussock Bellflower	Flowers and leaves, flowers used in salads	Fern (1992–2003)
<i>Campanula cochlearifolia</i> Lam	Fairies' Thimbles, Earleaf Bellflower	Flowers added to salad. Flowers eaten raw, added to salad, imparting a pleasant sweetness and a very attractive decoration to a salad	Fern (1992–2003)
<i>Campanula fenestrellata</i> Feer	Adriatic Bellflower	Flowers used as above added to salad	Fern (1992–2003)
<i>Campanula garganica</i> Ten.	Adriatic Bellflower	Flowers used as above	Fern (1992–2003)
<i>Campanula glomerata</i> L.	Crown Of Snow, Snow Crown	Flowers used as above	Fern (1992–2003), Deane (2007–2012q)
<i>Campanula lactiflora</i> M. Bieb.	Milky Bellflower	Flowers used as above	Fern (1992–2003)
<i>Campanula latifolia</i> L.	Giant Campanula, Large Campanula	Flowers used as above	Fern (1992–2003)
<i>Campanula latiloba</i> A. DC. = <i>Campanula grandis</i> subsp. <i>grandis</i>	Latiloba Campanula, Great Bellflower	Flowers used as above	Fern (1992–2003)
<i>Campanula medium</i> L.	Canterbury Bells, Bellflower	Flowers used as above	Fern (1992–2003)

<i>Campanula persicifolia</i> L.	Peach-Leaved Bellflower, Harebell, Willow Bell	Flowers used as above	Fern (1992–2003)
<i>Campanula portenschlagiana</i> Schult.	Dalmation Bellflower	Flowers used as above	Fern (1992–2003)
<i>Campanula poscharskyana</i> Degen	Serbian Bellflower, Trailing Bellflower	Flowers used as above	Fern (1992–2003)
<i>Campanula punctata</i> Lam.	Spotted Bellflower	Flowers and leaves cooked as potherb. The flowers make a decorative and tasty addition to the salad bowl	Read (1946), Tanaka (1976), Kunkel (1984), Facciola (1990), Fern (1992–2003), Dean (2007–2012q)
<i>Campanula pyramidalis</i> L.	Chimney Bellflower	Flowers eaten raw. A nice decorative addition to salads, the flowers have a pleasant sweet flavour	Fern (1992–2003)
<i>Campanula takesimana</i> Nakai = <i>Campanula punctata</i> var. <i>punctata</i>	Korean Bellflower	Flowers used as above	Fern (1992–2003)
<i>Campanula versicolor</i> Andrews	Bellflower	Flowers used as above	Fern (1992–2003), Dean (2007–2012q)
<i>Platycodon grandiflorus</i> (Jacq.) A.DC.	Balloon Flower, Japanese Bellflower, Common Balloon Flower	Blossoms sweet, used in salads, stuffed, candied or dipped in butter	Deane (2007–2012o)
<i>Wahlenbergia ceracea</i> Lothian	Alpine Bluebell, Waxy Bluebells	Flowers may be eaten, making a colourful (albeit tasteless) addition to a salad	Harden (1992), Steenbeeke (2001)
<i>Wahlenbergia communis</i> Carolin = <i>Wahlenbergia capillaris</i> (Lodd.) G. Don.	Tufted Bluebell	Flowers used as above	Harden (1992), Steenbeeke (2001)
<i>Wahlenbergia fluminialis</i> (J.M. Black) E. Wimm. ex H. Eichler	River Bluebell	Flowers used as above	Harden (1992), Steenbeeke (2001)
<i>Wahlenbergia gracilentia</i> Lothian	Annual Bluebell, Hairy Annual Bluebell	Flowers used as above	Harden (1992), Steenbeeke (2001)
<i>Wahlenbergia gracilis</i> (G. Forst.) A.DC.	Australian Bluebell	Flowers edible	Harden (1992), King (2007)
<i>Wahlenbergia graniticola</i> Carolin	Granite Bluebell	Flowers may be eaten, making a colourful (albeit tasteless) addition to a salad	Harden (1992), Steenbeeke (2001)
<i>Wahlenbergia littoricola</i> P.J. Sm.	Coast Bluebell	Flowers used as above	Harden (1992), Steenbeeke (2001)
<i>Wahlenbergia luteola</i> P.J. Sm.	Bronze Bluebell	Flowers used as above	Harden (1992), Steenbeeke (2001)
<i>Wahlenbergia multicaulis</i> Benth.	Tadgell's Bluebell	Flowers used as above	Harden (1992), Steenbeeke (2001)
<i>Wahlenbergia planiflora</i> P.J. Sm.	Bluebell	Flowers used as above	Harden (1992), Steenbeeke (2001)
<i>Wahlenbergia queenslandica</i> Carolin ex P.J. Sm.	Bluebell	Flowers used as above	Harden (1992), Steenbeeke (2001)

Table 1 (continued)

Scientific name	English/common vernacular name	Flower edible uses	References
<i>Wahlenbergia</i> sp.	Native Blue Bells	Flowers used in salads	Cribb and Cribb (1987), Low (1991), Symmons and Symmons (1994)
<i>Wahlenbergia stricta</i> (R.Br.) Sweet	Austral Bluebell, Tall Bluebell, Austral Bluebell	The flowers of <i>Wahlenbergia</i> may be eaten, making a colourful (albeit tasteless) addition to a salad	Harden (1992), Steenbeeke (2001)
<i>Wahlenbergia tumidiflucta</i> P.J. Sm.	Mallee Annual-Bluebell	Flowers used as above	Harden (1992), Steenbeeke (2001)
Cannabaceae			
<i>Humulus lupulus</i> L.	Hops, Common Hop; Pi-Jua-Hua (Chinese)	Pistillate inflorescence used for flavouring beer; buds eaten; dried flower heads used to flavour beer and liquor also used to leaven bread, used in tea, used in aperitif	Garland (1993), Hu (2005)
Capparaceae			
<i>Boscia albitrunca</i> (Burch.) Gilg and Benedict	Shepherd's Tree, Witgatboom, Matoppie	Flower buds pickled and used as caper substitute	Uphof (1968), Fox et al. (1982), Facciola (1990)
<i>Capparis arborea</i> (F. Muell.) Maiden	Native Pomegranate, Wild Lime, Wild Lemon, Brush Caper Berry	Edible flower buds pickled	Cribb and Cribb (1987), Low (1991), Symmons and Symmons (1994)
<i>Capparis decidua</i> (Forssk.) Edgew.	Caper, Kari; Kursan, Murkheit, Sodad, Tundub (Arabic); Meringa (Somali)	Flower bud eaten as potherb or pickled in India, Floral nectar also eaten in Rajasthan, India	Hedrick (1972), Bhandari (1974), Tanaka (1976), Saxena (1979), Facciola (1990)
<i>Capparis ovata</i> Desf. = <i>Capparis spinosa</i> L.	Caper, Caper Berry, Caper Bush	Flower buds can be pickled and used like capers	Kunkle (1984), Facciola (1990)
<i>Capparis sarmentosa</i> A. Cunn. ex Benth.	Climbing Caper	Edible flower buds pickled	Cribb and Cribb (1987), Low (1991), Symmons and Symmons (1994)
<i>Capparis sepiaria</i> L.	Indian Capers, Wild Caper Bush, Hedge Caper Bush	Flower buds can be pickled and used like capers	Tanaka (1976), Facciola (1990)
<i>Capparis spinosa</i> L.	Caper, Caper Berry, Caper Bush	Flower buds pickled and used to flavour sauces, butter, salads, stuffing, fish, meat, cheese and hors d'oeuvres	Hedrick (1972), Facciola (1990)
<i>Capparis spinosa</i> L. var: <i>maritima</i> (Jacq.) K. Schumann = <i>Capparis maritima</i> Jacq.	Caper, Caper Berry, Caper Bush	Pickled flower buds used to complement salty or oily foods, olives, salted meat and fish and to flavour casseroles	Garland (1993), Ong and Siemonsma (1999)
<i>Capparis velutina</i> P.I. Forst.	Kin Kin Scrub, Native Pomegranate	Edible flower buds pickled	Cribb and Cribb (1987), Low (1991), Symmons and Symmons (1994)

<i>Cratava adansonii</i> DC.	Garlic Pear Tree, Three-Leaf Caper, Obuse Leaf Crateva; Kumbok (Thai)	Flowers consumed as food	Wetitayaklung et al. (2008)
<i>Cratava magna</i> (Lour.) DC. = <i>Cratava religiosa</i> G. Forst.	Spider Tree, Sacred Garlic Pear, Three-Leaved Caper; Kum Nam (Thai)	Flowers consumed as food	Wetitayaklung et al. (2008)
<i>Cratava religiosa</i> G. Forst.	Spider Tree, Sacred Garlic Pear, Three-Leaved Caper; Kum Nam (Thai)	In Myanmar, the flowers are pickled and eaten for their digestive action	Hedrick (1972), Uphof (1968), Tanaka (1976), Facciola (1990)
Caprifoliaceae			
<i>Centranthus macrosiphon</i> Boiss	Long-Spurred Valerian, Pretty Betsy, Spur Valerian	Flowers eaten raw	Tanaka (1976)
<i>Lonicera affinis</i> Hook. and Arn.	Wild Honeysuckle, Coastal Honeysuckle; Hama-Nindou (Japanese)	Flowers used as a flavouring in drinks	Kunkel (1984)
<i>Lonicera caprifolium</i> L.	Goat-Leaf Honeysuckle, Italian Honeysuckle, Perfoliate Honeysuckle, Pefoliolate Woodbine	Flowers eaten	McVicar (2003)
<i>Lonicera henryi</i> Hemsley = <i>Lonicera acuminata</i> var. <i>acuminata</i>	Central China Honeysuckle; Xi Ye Ren Dong (Chinese)	Flowering shoots and flowers used for tea	Tanaka (1976), Facciola (1990), Hu (2005)
<i>Lonicera japonica</i> Thunb.	Japanese Honeysuckle; Jin Yin Hua, Er Hua, Shuang Hua (Chinese); Suikazura (Japanese)	Flower and buds used as ingredient in five-flower tea 'wu-hua cha' use in wine in China and beverage in Japan. The petals have also been used for making sorbet dessert. Flowers sucked for their sweet nectar and used as vegetable or made into syrup and puddings	Crowhurst (1972), Tanaka (1976), Facciola (1990), Barash (1997), Lauderdale and Evans (1999), Roberts (2000), Hu (2005)
<i>Patrinia scabiosifolia</i> Fisch. ex Trevir.	Yellow Patrinia, Golden Lace; Omina-Eshi (Japanese)	Flower buds eaten steamed, fried, oil-roasted, preserved, in soups, or parboiled and dried for later use	Tanaka (1976), Facciola (1990)
<i>Patrinia villosa</i> (Thunb.) Juss.	Patrinia; Bai Jiang Cao (Chinese), Otoko-Eshi (Japanese)	Flower buds eaten, fried, preserved or as potherb	Tanaka (1976), Facciola (1990)
<i>Sambucus australasica</i> (Lindl.) Fritsch	Yellow Elderberry	Flowers eaten raw or cooked	Cribb and Cribb (1987), Low (1991)
<i>Valeriana officinalis</i> L.	Valerian, Garden Valerian, Valerian Root	Flowers edible	McVicar (2003)

(continued)

Table 1 (continued)

Scientific name	English/common vernacular name	Flower edible uses	References
<i>Valerianella locusta</i> (L.) Laterr.	Corn Salad, Lamb's Lettuce, Lewiston Cornsalad	Inconspicuous flowers edible and flowering stems eaten raw	Larkcom (1980), Facciola (1990)
Caricaceae			
<i>Carica papaya</i> L.	Papaya	Inflorescence and flowers steamed, eaten with rice or added to soups and stews. In Indonesia, flowers are candied	Ochse and van den Brink (1980), Facciola (1990), Lim (2012a)
Caryophyllaceae			
<i>Dianthus barbatus</i> L.	Sweet William	The flowers can be crystallized. They have a mild flavour and are used as a garnish for vegetable and in fruit salads, cakes, desserts, cold drinks, lemonades butter and lemonade. The petals of Sweet Williams will add zest to ice cream, sorbets, salads, fruit salad, dessert sauces, seafood and stir-fries. It is advisable to remove the white heel at the base of the petal as this has a bitter taste	Facciola (1990), Lauderdale and Evans (1999), Anonymous (2012a)
<i>Dianthus caryophyllus</i> L.	Carnation, Pinks, Chinese Pink, Clove Pink	Flowers can be crystallized. The flower petals have a strong smell of cloves and are candied, used as a garnish in salads, for flavouring fruit, fruit salads, butter, lemonade, etc. They can also be used as a substitute for rose petals in making syrup. Petals preserved in sugar, syrup or vinegar and added to cordial, used to flavour food and drink, wine, tea, marmalade and sorbet. The petals should be removed from the calyx and their bitter white base should be removed	Morton (1976), Facciola (1990), Garland (1993), Barash (1997), Lauderdale and Evans (1999), Anonymous (2012a), Rop et al. (2012)
<i>Dianthus chinensis</i> L.	Dianthus, Pinks, Chinese Pinks	Most dianthus have a pleasant spicy, floral, clove-like taste, especially the more fragrant varieties, and are ideal for decorating or adding to cakes. They also make a colourful garnish to soups, salads and the punch bowl	Lauderdale and Evans (1999), Anonymous (2012a)
<i>Dianthus deltoides</i> L.	Maiden Pinks	Flowers used as above	Barash (1997), Lauderdale and Evans (1999), Anonymous (2012a)
<i>Dianthus plumarius</i> L.	Pink, Modern Border Pink	The petals are used in making cordials, syrups, sauces, salads, vinegars, lemonade and butter. They can be crystallized and used as garnish. Children suck the flowers for their sweet edible nectar	Tanaka (1976), Kunkel (1984), Facciola (1990), Anonymous (2012a)

<i>Dianthus</i> spp.	Carantions, Pinks	Flowers used as above	Lauderdale and Evans (1999), Newman and O'Connor (2009)
<i>Dianthus superbis</i> L.	Fringed Pink	Children suck the flowers for their sweet edible nectar	Tanaka (1976), Kunkel (1984), Facciola (1990), Lauderdale and Evans (1999), Anonymous (2012a)
<i>Paronychia argentea</i> Lam.	Algerian Tea, Silver Nailroot, Silvery Whitlow Wort	Infusion of flower used as tea	Uphof (1968), Facciola (1990)
<i>Paronychia capitata</i> (L.) Lam.	Algerian Tea, Whitlow Wort	Flowers used as substitute for tea	Uphof (1968), Facciola (1990)
<i>Petrohragia prolifera</i> (L.) P.W. Ball and Heywood	Childing Pink, Proliferous Pink	Flowers used as tea	Uphof (1968), Facciola (1990)
<i>Stellaria media</i> (L.) Vill.	Chickweed, Five-Petaled Chickweed, Chickenwort, Craches, Maruns, Winterweed	Flowering top used as vegetable or garnish	Cribb and Cribb (1987), Clarke (1977), Facciola (1990)
Celastraceae			
<i>Celastrus dependens</i> Wall. = <i>Celastrus paniculatus</i> subsp. <i>multiflorus</i> (Roxb.) D. Hou.	Black Ipecac, Black Oil Plant, Black Oil Tree, Celastrus Dependens, Climbing Staff Plant, Climbing Staff Tree, Dhimarbel, Intellect Tree	The young flowers are used as a vegetable	Facciola (1990)
<i>Celastrus paniculatus</i> Willd.	Shubby Bittersweet, Black Ipecac, Black Oil Plant, Black Oil Tree, Celastrus Dependens, Climbing Staff Plant, Climbing Staff Tree, Dhimarbel, Intellect Tree	Young flowers used as vegetable	Kunkel (1984)
Cleomaceae			
<i>Cleome gynandra</i> L.	African Spider Flower, Spider Flower, Shone Cabbage; Phak Sian (Thai)	Young shoots and young inflorescences are fermented in salt water and served with 'nam phrik'. The leaves are also eaten in soup with spareribs	Jircas (2010)
<i>Cleome integrifolia</i> Torr. and A. Gray = <i>Cleome serrulata</i> Pursh.	Rocky Mountain Beeplant, Bee Spider-Flower	Flowers boiled, eaten as potherb	Uphof (1968), Harrington (1974), Facciola (1990)
<i>Cleome monophylla</i> L.	Single-Leaved Cleome	Flowers eaten	Fox et al. (1982), Facciola (1990)
<i>Cleome serrulata</i> Pursh	Rocky Mountain Beeplant, Bee Spider-Flower	Young shoots, leaves and flowers are cooked and used as potherbs. Flowers used in New Mexico and Arizona	Yanovsky (1936), Uphof (1968), Tanaka (1976), Facciola (1990)
Clusiaceae			(continued)

Table 1 (continued)

Scientific name	English/common vernacular name	Flower edible uses	References
<i>Mammea americana</i> L.	Mamee Apple, Mamey	A liqueur called 'Eau de Créole', or 'Crème de Créole', is distilled from the fragrant white flowers	Morton (1987), Facciola (1990)
<i>Mesua ferrea</i> L.	Ceylon Ironwood, Indian Rose Chestnut, Cobra's Saffron, Mesua	Flowers eaten	Wessapan et al. (2007), Wettayaklung et al. (2008)
Combretaceae			
<i>Combretum grandiflorum</i> G. Don	Ohwirennini (Ghana – Akan-Asante); Fu Yayos (Gambia—Diola)	Flowers sucked for the nectar	Dalziel (1937), Facciola (1990)
<i>Combretum paniculatum</i> Vent.	Burning Bush, Forest Flame-Creeper (English); Bambagwena, Mupfurura (Zimbabwe—Shona)	Flowers sucked for the nectar	Dalziel (1937), Facciola (1990)
<i>Combretum platypterum</i> (Welw.) ex M.A. Lawson	Kyeramoa, O-Hwiremo Spaka (Ghana—Akan—Asante)	Flowers sucked for the nectar	Dalziel (1937), Facciola (1990)
<i>Quisqualis indica</i> L. = <i>Combretum indicum</i> (L.) DeFilipps	Chinese Honeysuckle, Drunken Sailor, Quisqualis, Rangoon Creeper, Red Jasmine	Flowers eaten in Thailand	Wettayaklung et al. (2008)
Commelinaceae			
<i>Commelina africana</i> L.	Yellow Commelina	Flowers eaten cooked	Deane (2007–2012n)
<i>Commelina communis</i> L.	Asiatic Dayflower	Leaves, flowers and young shoots eaten raw or cooked	Hedrick (1972), Tanaka (1976), Facciola (1990)
<i>Commelina cyanea</i> R.Br.	Native Wandering Jew, Wandering Sailor, Scurvy Weed	Flowers edible	King (2007)
<i>Rhoeo spathacea</i> Sw = <i>Tradescantia spathacea</i> Sw.	Oyster Plant, Moses-in-the-Cradle, Boat Lily, Moses-in-a-Boat; Bang Hua (Chinese)	Leafy shoots and flowers eaten in China	Hu (2005)
<i>Tradescantia virginiana</i> L.	Spiderwort, Indian Paint, Moses in the Bulrushes	Flowers eaten raw. They make an attractive edible garnish and can be made into candy	Fernald et al. (1958), Peterson (1977), Facciola (1990)
Convolvulaceae			
<i>Calonyction aculeatum</i> (L. House) = <i>Ipomea alba</i> L.	Moonflower, Moonlight Flower, Prickly Ipomea, Giant Moon Flower; Yue Guang Hua (Chinese); Terulak (Indonesian)	Leafy shoots and fleshy sepals eaten as potherb, dried flowers used for soup and also in pastries in Yunnan. In Indonesia, flowers used fresh or dried in 'kimlo' (a vegetable soup)	Ochse and van den Brink (1980), Hu (2005), Ng (2011)
<i>Calonyction album</i> (L. House) = <i>Ipomea alba</i> L.	Moonflower, Moonlight Flower; Prickly Ipomea, Giant Moon Flower; Yue Guang Hua (Chinese); Terulak (Indonesian)	As above	Burkill (1966), Martin and Ruberté (1975), Ochse and van den Brink (1980), Facciola (1990), Ng (2011)

<i>Ipomoea alba</i> L.	Moonflower, Moonlight Flower, Prickly Ipomoea, Giant Moon Flower; Yue Guang Hua (Chinese); Terulak (Indonesian)	As above	Hu (2005), Ng (2011)
Costaceae			
<i>Cheilocostus speciosus</i> (J. Koenig) C.D. Specht	Cane-Reed, Crape Ginger, Crepe Ginger, Elegant Costus, Malay Ginger, Spiral Flag, Spiral Ginger, Wild Ginger	Flowers edible in salad or as garnish	Carle (1995), Chan (1998)
<i>Costus barbatus</i> Suess.	Spiral Ginger, Red Tower Ginger	Flowers used as above	Carle (1995), King (2007)
<i>Costus erythrophyllus</i> Loes.	Blood Red Spiral Costus, Oxblood Ginger, Violet Spiral Flag	Flowers used as above	Carle (1995), King (2007)
<i>Costus productus</i> Gleason ex Maas	Costus Ginger, Dwarf Orange Ginger, Orange Tulip Ginger, Spiral Ginger	Flowers used as above	Carle (1995), Campbell (2006), NTBG (2013)
<i>Costus</i> spp.	Spiral Gingers	Many species, each with distinct citrus flavours—added to salads	Carle (1995), King (2007)
Cucurbitaceae			
<i>Benincasa hispida</i> (Thunberg ex Murray) Cogniaux cv-group Fuzzy Gourd Group	Fuzzy Gourd, Fuzzy Melon, Hairy Gourd, Hairy Melon	Young leaves and flower buds are steamed and eaten as a vegetable or are added as a flavouring to soups. Young shoots, flowers and fruits are consumed as vegetable in various parts of Thailand and Indonesia	Facciola (1990), Huxley et al. (1992), Jircas (2010), Lim (2012b)
<i>Benincasa hispida</i> (Thunberg ex Murray) Cogniaux cv-group Wax Gourd Group	Wax Gourd, Chinese Winter Melon, Wax Gourd; Fak, Fang (Thai)	As above	Jircas (2010), Lim (2012b)
<i>Benincasa hispida</i> Thunb.	Hairy Melon, Hairy Wax Gourd	Flowers, fruits and leaves relished as vegetables	Ochse and Bakhuizen van den Brink (1980), Facciola (1990), Woodward (2000), Lim (2012b)
<i>Cucurbita argyrosperma</i> C. Huber.	Cushaw, Green-Stripe Cushaw, Japanese Pie Pumpkin, White Cushaw, Silver Seed Gourd,	Flowers eaten cooked	Facciola (1990)
<i>Cucurbita filitcifolia</i> Bouché	Siam Pumpkin, Thin Vermicelli Pumpkin, Asian Pumpkin, Fig Leaf Gourd, Pie Melon, Malabar Gourd, Thai Marrow	Flowers are eaten	Widjaja and Sukprakam (1994), Lim (2012b)
<i>Cucurbita foetidissima</i> Kunth	Buffalo Gourd	Flowers said to be edible after preparation	Facciola (1990)

(continued)

Table 1 (continued)

Scientific name	English/common vernacular name	Flower edible uses	References
<i>Cucurbita maxima</i> Duchesne ex Lam.	Squash, Pumpkin, Buttercup Squash	Flowers, fruits and leaves relished as vegetables	Widjaja and Sukprakarn (1994), Newman and O'Connor (2009), Lim (2012b)
<i>Cucurbita mixta</i> Pangalo = <i>Cucurbita argyrosperma</i> Huber.	Cushaw Pumpkin, Squash	Flowers edible	Widjaja and Sukprakarn (1994)
<i>Cucurbita moschata</i> (Duchesne ex Lam.) Duchesne ex Poiret	Squash, Pumpkin, Butternut Squash, Long Island Cheese Pumpkin; Fak Thong (Thai), Kabocha (Japanese)	Young leaves unopened flower Mature fruit is commonly used as ingredient of various kinds of spicy vegetable soups. Young shoots, flowers and fruits are also eaten	Herklots (1972), Ochse and van den Brink (1980), Facciola (1990), Widjaja and Sukprakarn (1994), Newman and O'Connor (2009), Jircas (2010), Lim (2012b)
<i>Cucurbita pepo</i> L.	Squash, Gourd, Pumpkin, Vegetable Marrow, Zucchini, Calabashes, Acorn Squash, Summer Pumpkin, Autumn Pumpkin	Flowers, fruits and leaves relished as vegetables	Widjaja and Sukprakarn (1994), Barash (1997), Lauderdale and Evans (1999), Newman and O'Connor (2009), Lim (2012b)
<i>Cucurbita</i> spp.	Pumpkin, Squash, Vegetable Marrow, Zucchini, Calabashes, Acorn Squash	Flowers used in desserts and puddings	Barash (1997), Newman and O'Connor (2009), Dean (2007–2012a)
<i>Lagenaria siceraria</i> (Molina) Standley	Bottle Gourd, Calabash Gourd	Young tender fruits, young shoots, leaves and flower buds of non-bitter varieties eaten as vegetables in Asia and Africa	Lim (2012b)
<i>Luffa aegyptiaca</i> P. Miller	Bath Sponge, Smooth Luffa, Dish Cloth Gourd, Sponge Gourd	Flowers, buds, young fruits and leaves relished as vegetables	Lim (2012b)
<i>Luffa acutangula</i> (L.) Roxb.	Angled Luffa	Flowers, buds, young fruits and leaves relished as vegetables	Herklots (1972), Facciola (1990), Jansen et al. (1994), Woodward (2000), Lim (2012b)
<i>Luffa cylindrica</i> (L.) M. Roem. = <i>Luffa aegyptiaca</i> P. Miller	Bath Sponge, Smooth Luffa, Dish Cloth Gourd, Sponge Gourd	Flowers, buds, young fruits and leaves relished as vegetables	Herklots (1972), Ochse and van den Brink (1980), Facciola (1990), Jansen et al. (1994), Lim (2012b)
<i>Momordica charantia</i>	Bitter Gourd, Bitter Melon	Fragrant yellow blossoms can be used for flavouring	Reyes et al. (1994), Lim (2012a, b)
<i>Momordica cochinchinensis</i> Loureiro	Giant Spine Gourd (English), Nanban Kikarasuuri (Japanese), Fak Khao (Thai), Gac (Vietnamese)	In Thailand, young fruits, shoots and flowers are ingredient of curry. After boiling, they are eaten with chilli sauces and rice. Young shoots are fried with oyster sauce with pork or shrimp	Jircas (2010), Lim (2012b)

Cycadaceae				
<i>Cycas siamensis</i> Miq.	Silver Cycas, Thai Silver Cycas; Prong (Thai)	Core of young conical flower bud eaten after prolonged cooking	Pongpangan and Poobarasert (1985)	
Cyperaceae				
<i>Scirpus lacustris</i> L. = <i>Schoenoplectus lacustris</i> (L.) Palla.	Great Bulrush	Pollen mixed with meal for making bread	Harrington (1974), Facciola (1990)	
<i>Scirpus paludosus</i> A. Nelson = <i>Bolboschoenus maritimus</i> subsp. <i>paludosus</i> (A. Nelson) T. Koyama	Alkali Bulrush	Pollen mixed with meal for making bread by Indian tribes	Fernand et al. (1958), Upholf (1968), Facciola (1990)	
<i>Scirpus validus</i> Vahl = <i>Schoenoplectus tabernaemontani</i> (C.C. Gmel.) Palla	Tall Bulrush, Great American Bulrush	Pollen used in soups and bread	Fernand et al. (1958), Tanaka (1976), Facciola (1990)	
Dilleniaceae				
<i>Dillenia indica</i> L.	Chulta, Dillenia, Elephant-Apple, Hondapare Tree, Indian Catmon; San Plao, Matad (Thai)	In India (Deccan and Garhwal Himalayas) innermost sepals used to flavour food and eaten. A syrup is made from the flower sepals	Pongpangan and Poobarasert (1985), Watt (1908), Patiri and Borah (2007), Lim (2012b)	
<i>Dillenia pentagyna</i> Roxb.	Karmal, Dog Teak, Dillenia, Nepali Elephant Apple; Agachi (Garo); Dieng Soh Karbam (Khasi)	Flowers India (Bombay Presidency): flowers especially the fleshy calyces and fruits eaten as vegetable in Assam. Flower buds have a pleasant acid flavour, eaten raw or cooked in Oudh and Central India	Gamie (1902), Seal, (2012), Patiri and Borah (2007)	
<i>Dillenia philippinensis</i> Rolfe	Philippine Catmon, Philippine Dillenia	Flowers used as flavouring for sour fish soup	Lim (2012b)	
<i>Dillenia serrata</i> Thunb.	Dengen, Dongi Bolusu, Songi (Borneo)	Yellow carpels eaten	Lim (2012b)	
Dioscoreaceae				
<i>Dioscorea pentaphylla</i> L.	Five-Leaved Yam	Flowers eaten in the Deccan, India	Watt (1908)	
Dipterocarpaceae				
<i>Dipterocarpus obtusifolius</i> Teijsm. ex Miq.	Hiang (Thai); Mai Xat (Laotian)	Flowers sour, edible raw	Pongpangan and Poobarasert (1985)	
<i>Shorea talura</i> Roxb.	Lac Tree, Lac Tree Of South India; Payom (Thai)	Flowers eaten cooked	Pongpangan and Poobarasert (1985)	
Doryanthaceae				
<i>Doryanthes excelsa</i> Corrêa	Gymea Lily, Flame Lily	Flower stalk, young flower heads were eaten after steaming as a traditional aboriginal food	Low (1989), Kapitany (2012)	(continued)

Table 1 (continued)

Scientific name	English/common vernacular name	Flower edible uses	References
Ericaceae			
<i>Acrotiche attenuata</i> F. Muell.	Trailing Ground-Berry	Abundant flower nectar sucked by children	Cribb and Cribb (1987)
<i>Acrotiche prostrata</i>	Trailing Ground-Berry	Abundant flower nectar sucked by children	Cribb and Cribb (1987)
<i>Acrotiche serrulata</i> (Labill.) R.Br.	Honeypots, Heath	Tiny flowers eaten	Low (1989)
<i>Agapetes variegata</i> (Roxb.) D. Don ex G. Don	Agapetes	Flowers cooked eaten with rice in India	Altschul (1973), Facciola (1990)
<i>Arctostaphylos glauca</i> Lindl.	Bigberry Manzanita	Blossom eaten as nibbles	Deane (2007–2012q)
<i>Arctostaphylos manzanita</i> Parry	Common Manzanita, Whiteleaf Manzanita	Blossom eaten as nibbles	Deane (2007–2012q)
<i>Arctostaphylos nevadensis</i> A. Gray	Pinemat Manzanita	Blossom eaten as nibbles	Deane (2007–2012q)
<i>Arctostaphylos parryana</i> Lemmon	Parry Manzanita	Blossom eaten as nibbles	Deane (2007–2012q)
<i>Arctostaphylos patula</i> Greene	Greenleaf Manzanita	Blossom eaten as nibbles	Deane (2007–2012q)
<i>Arctostaphylos pungens</i> Kunth	Pointleaf Manzanita	Blossom eaten as nibbles	Deane (2007–2012q)
<i>Arctostaphylos tomentosa</i> (Pursh.) Lindl.	Downy Manzanita	Blossom eaten as nibbles	Deane (2007–2012q)
<i>Azalea indica</i> L.	Pink Azalea	Flowers edible	Tanaka (1976)
<i>Azalea oldhamii</i> (Maxim.) Mast. = <i>Rhododendron oldhamii</i> Maxim.	Rhododendron, Azalea	Flower petals sometimes eaten	Tanaka (1976)
<i>Calluna vulgaris</i> (L.) Hull	Common Heather, Heather	Dried flower heads made a good tea	Hedrick (1972), Facciola (1990)
<i>Erica cerinthoides</i> L.	Fire Erica, Fire Heath, Red Hairy Heath	Flowers sucked for nectar	Kunkel (1984)
<i>Gaultheria appressa</i> A. W. Hill	White Waxberry	The swollen calyx of the flower is succulent, surrounding the seed at maturity. It is somewhat bitter and has little to recommend it as a food	Harden (1992), Steenbeeke (2001)
<i>Gaultheria viridicarpa</i> I. Telford and J.B. Williams	Waxberry	As above	Harden (1992), Steenbeeke (2001)
<i>Ledum columbianum</i> Piper = <i>Rhododendron columbianum</i> (Piper) Harmaja.	Pacific Labrador Tea	Light delicate beverage made by boiling over leaves and or flowers	Schofield (2003)
<i>Ledum glandulosum</i> Nutt.	Western Labrador Tea	As above	Schofield (2003)
<i>Ledum palustre</i> ssp. <i>decumbens</i> (Aiton) Hultén = <i>Ledum palustre</i> var. <i>decumbens</i> Aiton	Labrador Tea	As above	Schofield (2003)

<i>Ledum palustre</i> ssp. <i>groenlandicum</i> (Oeder) Hultén = <i>Rhododendron groenlandicum</i> (Oeder) Kron and Judd.	Labrador Tea	As above	Schofield (2003)
<i>Melichrus procumbens</i> (Cav.) Druce	Honeypot, Jam-Pot Jam-Tart Heath	Small blossoms make sweet tea and have an abundant nectar	Cribb and Cribb (1987), Low (1989)
<i>Melichrus urceolatus</i> R.Br.	Urn-Heath	Abundant nectar	Cribb and Cribb (1987)
<i>Rhododendron arboreum</i> Sm	Red Rhodendron; Lali Gurans (Nepali); Burans (Garhwali); Eras (Kumaoni); Adrawal (Punjab); Billi (Tamil); Pu (Kannada); Kattupoo Varasu (Malayalam)	The fresh and dried flowers have a sweet and sour taste and are used in the preparation of squash, jams, jellies and local pleasant brew drank daily as refreshing appetizer and also to prevent high-altitude sickness. Fresh petals are used to prepare a chutney known as 'barah ki chutney'	Gupta (1962), Hedrick (1972), Tanaka (1976), Pradhan and Lachungpa (1990), Facciola (1990), Namrata et al. (2011), Srivastava (2012)
<i>Rhododendron indicum</i> (L.) Sweet	Rhododendron, Southern Indica Hybrid Azaleas; Otakumi Tutuji (Japanese)	Flowers eaten raw or cooked	Tanaka (1976), Kunkel (1984), Facciola (1990)
<i>Rhododendron kaempferi</i> Planch.	Torch Azalea, Kaempferi Azalea	Flowers eaten raw or cooked	Tanaka (1976), Kunkel (1984), Facciola (1990)
<i>Rhododendron lapponicum</i> (L.) Wahlenb.	Lapland Rosebay	Flower tops used as substitute for tea	Hedrick (1972)
<i>Rhododendron mucronulatum</i> Turcz.	Korean Rhodendron; Ying Hong Du Juan (Chinese); Jindallae (Korean)	Flower petals used in Hwajeon flower glutinous rice cake	Tanaka (1976), Wikipedia (2012)
<i>Richea scoparia</i> Hooker f.	Scoparia, Alpine Richea	Flowers sucked for nectar	Schaeffer and Fletcher (2012)
<i>Styphelia</i> sp.	Five Corners	Flower sucked for nectar	Low (1989)
<i>Vaccinium myrtilloides</i> Michx.	Bilberry, Bulberry, Whortleberry, Huckleberry, Hurtleberry, Blueberry, Trackleberry, Whinberry, Bleaberry, Airelle, Fraughan	The flowers can be eaten raw or used to make preserves	Moerman (1998)
<i>Vaccinium vaciniaceum</i> (Roxb.) Steumer.	Tu Guan Xiao Lun Ye Yue Ju (Chinese)	The acid-tasting flowers are used in curries	Kunkel (1984)
<i>Epigaea repens</i> L.	Mayflower, Trailing Arbutus	Flowers have a spicy slightly acid flavour; they are eaten as a wayside nibble or are added to salads as a thirst quencher	Tanaka (1976), Kunkel (1984), Facciola (1990)
Euphorbiaceae			
<i>Chrozophora plicata</i> (Vahl) A. Juss. ex Spreng.	Giradol	Petals provide a red and blue dye used for colouring liquors, wine, pastries and Dutch cheeses	Uphof (1968), Facciola (1990)

Table 1 (continued)

Scientific name	English/common vernacular name	Flower edible uses	References
<i>Croton corymbulosus</i> Engelm. = <i>Croton pottsii</i> var. <i>pottsii</i> (Klotzsch) Müll. Arg.	Leatherweed	Infusion of flowering tops used as beverage in Texas	Yanovsky (1936)
<i>Euphorbia hirta</i> L.	Common Spurge, Asthma Weed, Hairy Spurge, Garden Spurge; Pakhang Leiton (Manipur)	Young shoots and inflorescences eaten	Yunnum and Tripathi, (2012)
<i>Euphorbia pulcherrima</i> Willd. ex Klotzsch	Poinsettia, Christmas Star, Christmas Flower, Painted Leaf, Lobster Plant, Mexican Flameleaf, Crown of the Andes	Young shoot, inflorescence and leaves steamed or stewed	Ochse and van den Brink (1980)
<i>Euphorbia tetragona</i> Haw.	Naboom	Flowers rich in nectar sometimes used in confectionary	Facciola (1990)
<i>Ricinus communis</i> L.	African Coffee Tree, Castor, Castor Bean, Castor Oil, Castor Oil Plant	Young inflorescences boiled	Uphof (1968), Hedrick (1972), Facciola (1990)
Fabaceae			
<i>Acacia aneura</i> F. Muell. ex Benth.	Mulga Acacia	Flowers cooked, often in fritters	Cribb and Cribb (1987)
<i>Acacia concinna</i> (Willd.) DC.	Soap Pod	Flowers used as vegetable	Hedrick (1972), Altschul (1973), Facciola (1990)
<i>Acacia coriacea</i> DC.	Wiry Wattle, Wire Wood	Flowers edible	Wikipedia (2012)
<i>Acacia cultriformis</i> A. Cunn. ex G. Don.	Knife-Leaf Wattle	Flowers cooked, often used in fritters	Cribb and Cribb (1987)
<i>Acacia dealbata</i> Link	Mimosa	Flowers used as above	Cribb and Cribb (1987)
<i>Acacia decurrens</i> Willd.	Acacia Bark, Early Black Wattle, Green Wattle, Sydney Wattle, Wattle Bark, Tan Wattle, Golden Teak, Brazilian Teak	Flowers used as above	Cribb and Cribb (1987)
<i>Acacia farnesiana</i> (L.) Willd.	Farnese Wattle, Mimosa Wattle, Cassie Flower	Flowers edible	Stangland (2004), McCullough (2007), Department of the Army (2009)
<i>Acacia longifolia</i> (Andrews) Willd.	Long-Leaved Wattle, Acacia Trinervis, Aroma Doble, Golden Wattle, Coast Wattle, Sallow Wattle, Sydney Golden Wattle	Flowers cooked, often used in fritters	Cribb and Cribb (1987)
<i>Acacia macradenia</i> Benth.	Zig-Zag Wattle	Flowers edible	King (2007)
<i>Acacia melanoxylon</i> R.Br.	Blackwood, Hickory, Sally Wattle, Tasmanian Blackwood, Mudgerabah	Flowers cooked, often used in fritters	Cribb and Cribb (1987)

<i>Acacia mucronata</i> Wendl.	Narrow-Leaf Wattle	Flowers used as above	Cribb and Cribb (1987), Fern (1992–2003)
<i>Acacia nilotica</i> (L.) Delile	Egyptian Mimosa, Egyptian Thorn	Flowers used as above	MacNicol (1967), Tanaka (1976), Facciola (1990)
<i>Acacia oshanesii</i> F. Muell. and Maiden	Irish Wattle	Wattle flowers steeped in liqueur, coated with sugar and batter before deep frying	Deane (2007–2012w)
<i>Acacia paradoxa</i> DC.	Kangaroo Thorn, Prickly Wattle, Hedge Wattle, Paradox Acacia	Flowers cooked, often used in fritters	Cribb and Cribb (1987)
<i>Acacia podalyriifolia</i> Cunn. ex Don	Silver Wattle, Mt Morgan Wattle	Wattle flowers steeped in liqueur, coated with sugar and batter before deep frying	Cribb and Cribb (1987), Facciola (1990), Deane (2007–2012w)
<i>Acacia pycnantha</i> Benth.	Golden Wattle Broad-Leaved Wattle, Witch	Flowers cooked, often used in fritters	Cribb and Cribb (1987)
<i>Acacia retinodes</i> Schldl.	Retinodes Water Wattle, Swamp Wattle, Wirilda, Ever-Blooming Wattle, Silver Wattle	Flowers cooked, often used in fritters	Cribb and Cribb (1987)
<i>Acacia saligna</i> (Labill.) H.L. Wendl.	Coojong, Golden-Wreath Wattle, Orange Wattle, Blue-Leaved Wattle, Port Jackson Willow	Flowers cooked, often used in fritters	Cribb and Cribb (1987)
<i>Acacia sophorae</i> (Labill.) R.Br.	Boobyalla, Coast Wattle, Coastal Wattle, False Boobyalla, Sallow Wattle	Flowers cooked, often used in fritters	Cribb and Cribb (1987)
<i>Acacia spectabilis</i> A. Cunn. ex Benth.	Mudgee Wattle, Glory Wattle, Pilliga Wattle, Golden Wattle	Wattle flowers steeped in liqueur, coated with sugar and batter before deep frying or mixed into the batter of pikelets and pancakes	Cribb and Cribb (1987), Facciola (1990), Deane (2007–2012w)
<i>Acacia verticillata</i> (L'Hér.) Willd.	Prickly Moses, Prickly Mimosa	Flowers cooked, often used in fritters	Cribb and Cribb (1987)
<i>Aeschynomene aspera</i> L.	Sola, Sola Pith Plant, Pith Plant; Chigonglei (Manipur)	Flowers used extensively in cooking during Cheiraoba, the New Year of the Meitei community in Manipur, India	Hauzel (2012)
<i>Albizia julibrissin</i> Durazz	Mimosa, Persian Silk Tree, Pink Siris, Lenkortan Acacia, Bastard Tamarind	Flowers eaten as a cooked vegetable or crystallized	Kunkel (1984), Facciola (1990)
<i>Arachis pintoi</i> Krapov. and W.C. Gregory	Pinto Peanut, Perennial Peanut, Golden Glory	Yellow flowers are edible	Wallace (2009)
<i>Astragalus multiceps</i> Benth.	Kandiara	The calyx of the flower is eaten and has a sweetish flavour	Kunkel (1984)

<i>Bauhinia variegata</i> L.	Indian Orchid Tree, Bauhinia, Butterfly Ash, Butterfly Tree, Camel's Foot, Camel's Foot Tree, Mountain Ebony, Orchid Tree, Orchidtree, Poor Man's Orchid, Pink Orchid Tree, Purple Orchid Tree, Variegated Orchid Tree, Variegated Orchid-Tree, White Bauhinia, White Camel's Foot, White Variegated Orchid Tree; Yang- Ti Jia (Chinese)	Young flower buds, young leaves and pods eaten in curries in India (Garhwal Himalayas) and salad. Young leaves, flower buds, flowers and young fruits used as vegetables in Hainan island. Flowers used for their nectar; buds and flowers cooked and pickled	Darlington and Ammal (1945), Gupta (1962), Hedrick (1972), Tanaka (1976), Kunkel (1984), Facciola (1990), Hu (2005), Patiri and Borah (2007), Namrata et al. (2011), Deane (2007–2012h)
<i>Caesalpinia gillesii</i> (Hook.) D. Dietr.	Bird-of-Paradise Shrub, Yellow Bird of Paradise Tree	Flower stamens used to adulterate saffron	Facciola (1990)
<i>Caesalpinia pulcherrima</i> (L.) Sw.	Peacock Flower, Pride Of Barbados, Dwarf Poinciana, Barbados Flower-Fence, Red Bird-of-Paradise	Flowers lightly cooked and eaten	Tanaka (1976), Pongpangan and Poobarsert (1985), Facciola (1990), King (2007)
<i>Callistemon</i> spp.	Bottle Brushes	Flower spikes steeped in warm water for the nectar	Schaeffer and Fletcher (2012)

<i>Canavalia ensiformis</i> (L.) DC.	Common Jack Bean, Ensiform Bean	Young leaves, flowers eaten steamed as 'alab'	Ochse and van den Brink (1980)
<i>Canavalia gladiata</i> (Jacq.) DC.	Sword Bean; Thua Phraa, Thua Daap, Thua Faa (Thai); Nataname (Japanese)	The young shoots, young pods and flowers of the sword bean are served blanched with nam 'phrik'. The sour-tasting leaves are put in tom yam soup or eaten blanched with vermicelli and peanut curry. The young pods can be used in curries or fried	Kooi (1994), Saidin (2000), Jircas (2010), Lim (2012b)
<i>Canavalia maritima</i> (Aubl.) Urb. = <i>Canavalia rosea</i> (Sw.) DC.	Beach Bean, Bay Bean, Seaside Jack-Bean, Coastal Jack-Bean, Mackenzie Bean, Wonder Bean	In Malaysia, flowers eaten as flavouring	Burkill (1966), Facciola (1990)
<i>Caragana ambigua</i> Stocks	Pea Shrub	Flowers eaten raw or cooked	Hedrick (1972), Tanaka (1976)
<i>Caragana sinica</i> (Buc'hoz.) Rehder.	Chinese Pea Shrub	Flowers eaten raw or cooked	Uphof (1968), Tanaka (1976), Kunkel (1984)
<i>Cassia auriculata</i> L. = <i>Senna auriculata</i> (L.) Roxb.	Avaram Senna; Ranawara, Avaram (Telugu); Tangedu (Andhra Pradesh)	Flowers eaten as vegetable in Andhra Pradesh, India. Dried flowers used as coffee substitute	Watt (1908), Facciola (1990), Rahmansyah (1992), Reddy et al. (2007)
<i>Cassia fistula</i> L.	Cascara, Golden Shower, Indian Laburnum. Pudding Pipe Tree; Raela (Andhra Pradesh); Sonaru (Assamese)	Flowers eaten in Andhra Pradesh, India; flowers eaten by Santal people; flowers and buds eaten cooked in Assam	Watt (1908), Facciola (1990) Reddy et al. (2007), Patiri and Borah (2007), Lim (2012b)
<i>Cassia garrettiana</i> Craib = <i>Senna garrettiana</i> (Craib) H.S. Irwin and Barneby	Manatapat; Ki Lek Maeng, Khi Lek San, Khi Lek Kao, Samae Sam (Thai)	Young leaves, flowers bitter cooked as food	Pongpangan and Poobarasert (1985)
<i>Cassia hookeriana</i> Hook. = <i>Senna birostris</i> var. <i>hookeriana</i> (Hook.) H.S. Irwin and Barneby	Mutuy (Quechua)	Flowers boiled and eaten in Peru (Vilcanota Valley)	Gade (1975)
<i>Cassia latopetiolata</i> Vogel = <i>Senna versicolor</i> (Vogel) H.S. Irwin and Barneby	Mutuy (Quechua)	Flowers boiled and eaten in Peru (Vilcanota Valley)	Gade (1975)
<i>Cassia occidentalis</i> = <i>Senna occidentalis</i> (L.) Link	Coffee Senna, Negro Coffee, Coffee Weed, Stinking Weed; Khi Lek Phi, Chum Het Lek (Thai)	Flowers eaten as steamed vegetables	Fernand et al. (1958), Ochse and van den Brink (1980), Facciola (1990)
<i>Cassia siamea</i> Lam. = <i>Senna siamea</i> (Lam.) H.S. Irwin and Barneby	Khi Lek Yai (Thai)	Flowers cooked as vegetables by Garos in Lower Assam; flowers cooked in curries in Thailand	Maisuthisakul et al. (2008), Maisuthisakul (2012), Kusamaran et al. (1998), Rojampo and Tepsuwan (1992, 1993), Patiri and Borah (2007), Kaisoon et al. (2011)

Scientific name	English/common vernacular name	Flower edible uses	References
<i>Cassia sophora</i> (L.) Wall. = <i>Senna sophora</i> (L.) Roxb.	African Senna, Pepper Leaved Senna; Kasaunda (Hindi); Phak Wan Ban, Phak Khet, Phak Khlet (Thai)	Flowers eaten in China	Read (1946)
<i>Cassia timoriensis</i> DC = <i>Senna timoriensis</i> (DC.) H.S. Irwin and Barneby	Wild Cassia; Khi Lek Lueat, Khi Lek Pa, Khi Lek Daeng (Thai)	Young leaves, flowers bitter cooked as food	Pongpangan and Poobarasert (1985)
<i>Cassia tomentosa</i> L.f. = <i>Senna multiglandulosa</i> (Jacq.) H.S. Irwin and Bameby	Mutuy (Quechua)	Flowers boiled and eaten in Peru (Vilcanota Valley)	Gade (1975), Facciola (1990)
<i>Cercis canadensis</i> L.	Eastern Redbud, Judas Tree, Redbud Red Bud Tree	Flowers eaten raw in salad, cooked or pickled; unopened buds pickled used as caper substitute	Uphof (1968), Hedrick (1972), Usher (1974), Tanaka (1976), Facciola (1990), Roberts (2000), Newman and O'Connor (2009)
<i>Cercis occidentalis</i> A. Gray	Western Redbud, Californian Redbud	Flowers eaten raw, added to salads, buds pickled	Yanovsky (1936), Facciola (1990)
<i>Cercis siliquastrum</i> L.	Judas Tree, Love Tree	Flowers eaten raw, have a sweetish-acid taste and make a nice addition to the salad bowl	Hedrick (1972), Tanaka (1976), Facciola (1990), Roberts (2000)
<i>Clanthus puniceus</i> (G. Don.) Lindl.	Parrot's Beak, Kaka-Beak Parrot's Bill, Lobster Claw	Flowers have a crisp and leafy taste	D'Cruz (1998)
<i>Clitoria ternatea</i> L.	Butterfly Pea, Blue-Pea and Cordofan-Pea	Flowers used as a food colourant; used in salad, dessert and as vegetable	Hedrick (1972), Burkil (1966), Wetitayaklung et al. (2008), Kaisoon et al. (2011)
<i>Crotalaria glauca</i> Willd.	Grass-Leaved Crotalaria	Flowers eaten as potherb	Hedrick (1972)
<i>Crotalaria longirostrata</i> Hook. and Arn.	Chepil, Chepilin, Chipilin, Longbeak Rattlebox	Flowers eaten	Uphof (1968), Williams (1981), Facciola (1990)
<i>Crotalaria ochroleuca</i> G. Don	Slender Leaf Rattlebox	Flowers eaten	Kunkel (1984), Facciola (1990)
<i>Cytisus scoparius</i> (L.) Link	Scotch Broom, Broom, Hogweed	The flower buds are pickled and used as a substitute for capers. Young buds and flowering tops used in cooking, bitter buds eaten as salad, fresh or pickled, and in herbal tea	Uphof (1968), Grieve (1971), Facciola (1990), Phillips and Foy (1992), Garland (1993)
<i>Diphyssa robinoides</i> Millsp. = <i>Diphyssa carthagenensis</i> Jacq.	Macano, Palo Amarillo	Yellow flowers becomes mucilaginous when steamed and added to beans or tortilla	Facciola (1990)
<i>Dolichos lablab</i> L. = <i>Lablab purpureus</i> (L.) Sweet	Hyacinth Bean, Lablab Bean, Field Bean, Pig-Ears, Rongai Dolichos, Lab-Lab Bean, Poor Man's Bean, Tonga Bean; Kwao-Nam (Thai)	Flowers cooked as vegetables in spicy stir-fry or eaten dipped in spicy chilli sauce	Pongpangan and Poobarasert (1985), Saidin (2000)

<i>Dolichos malosanus</i> Baker = <i>Dolichos kilimandscharicus</i> subsp. <i>kilimandscharicus</i> Taub.	Veld Lupin	Flowers consumed as vegetables by natives	Uphof (1968), Facciola (1990)
<i>Erythrina americana</i> Mill.	American Coral Tree, Naked Coral Tree, Flor De Colorin	In Mexico, the flowers and immature inflorescences are eaten especially in tamales at Easter time	Kunkel (1984), Facciola (1990)
<i>Erythrina berteriana</i> Urb.	Coral Bean, Pito Coral Tree	Flowers and immature inflorescences are eaten with meat, in stews and in egg dishes	Martin and Ruberté (1975), Tanaka (1976), Facciola (1990)
<i>Erythrina flabelliformis</i> Kearney	Coralbean, Southwestern Coral Bean	Flowers reported edible and relished in Mexico	Deane (2007c)
<i>Erythrina glauca</i> Willd. = <i>Erythrina fusca</i> Lour.	Purple Coraltree, Gallito, Bois Immortelle, Bucayo	Flowers folded into batter, cooked and eaten	Williams (1981), Facciola (1990)
<i>Erythrina herbacea</i> L.	Eastern Coral Bean, Cardinal Spear	Flowers eaten cooked	Facciola (1990), Deane (2007–2012c)
<i>Erythrina rubrinervia</i> Kunth	Gallito, Palo De Pito, Palo Santo, Pemmilla De Casa, Peronil	Flowers and flower buds eaten like string beans in El Savador and Guatemala	Altschul (1973), Uphof (1968), Facciola (1990)
<i>Erythrina variegata</i> L.	Variegated Coral Tree, Indian Coral Bean, Tigers-Claw, Variegated Coralbean, Variegated Coraltree, Indian Coraltree, Indian Wiliwili	The flowers and young leaves are edible and cooked like string beans in water	Deane (2007–2012c)
<i>Gliricidia sepium</i> (Jacq.) Walp.	Madre De Cacao, Gliricidia, Mexican Lilac, Mother of Cocoa, Nicaraguan Cacao Shade, Quick Stick, St. Vincent Plum, Tree of Iron	Flowers cooked in egg batter and fried or cooked as potherbs	Williams (1981), Facciola (1990)
<i>Hardenbergia violacea</i> (Schneev.) Stearn	Native Sarsaparilla, False Sarsaparilla Vine	Purple flowers eaten raw	Haslam (2011)
<i>Indigofera pulchella</i> Roxb. = <i>Indigofera cassioides</i> DC.	Cassia Indigo	Flowers occasionally eaten as vegetables	Watt (1908), Tanaka (1976)
<i>Indigofera cassioides</i> DC.	Cassia Indigo	The flowers are occasionally eaten as a vegetable	Kunkel (1984), Facciola (1990)
<i>Indigofera dosua</i> D. Don	Kathewat, Kati, Theot (Hawaiian)	Flowers eaten as potherb in India	Watt (1908)
<i>Indigofera gerardiana</i> Baker = <i>Indigofera heterantha</i> Brandis.	Himalayan Indigo, Gerard's Indigo	Flowers eaten in India (Garhwal Himalayas)	Gupta (1962)
<i>Indigofera hebeptata</i> Baker	Fuzzy Petal Indigo	The flowers and tender immature pods are cooked as a vegetable or pickled	Manandhar (1991)
<i>Indigofera heterantha</i> Brandis	Himalayan Indigo, Indigo Bush	The flowers are boiled and pickled	Manandhar (1991)
<i>Indigofera pseudotinctoria</i> Matsum.	False Indigo	The leaves and flowers are boiled and eaten in China	Read (1946), Tanaka (1976), Kunkel (1984), Facciola (1990)

<i>Kraunhia floribunda</i> (Willd.) Taub. = <i>Wisteria floribunda</i> (Willd.) DC.	Japanese Wisteria	Flowers thoroughly boiled, washed and eaten with oil and salt in China	Read (1946), Deane (2007–2012)
<i>Lablab purpureus</i> (L.) Sweet	Hyalanth Bean, Lablab Bean, Field Bean, Pig-Ears, Rongai Dolichos, Lab-Lab Bean, Poor Man's Bean, Tonga Bean; Kwao-Nam (Thai)	Flowers eaten raw or steamed, or added to soups and stews	Fernald et al. (1958), Hedrick (1972), Pongpangan and Poobrasert (1985), Facciola (1990), Tanaka and Nguyen (2007)
<i>Lathyrus davidii</i> Hance	Chin Yin Hua, Da Shan Li Dou, Jiang Mang Shan Li Dou, Jiang Mang Xiang Wan Dou, Shan Jiang Dou, Shan Chiang Tou (Chinese); Itachi Sasage (Japanese)	Young plant, including the inflorescence is cooked and used as a potherb or added to soups	Tanaka (1976), Kunkel (1984), Facciola (1990)
<i>Lespedeza bicolor</i> Trucz.	Tartary Bush Clover; Hu Zhi Zi (Chinese); Yama-Hagi (Japanese),	Young leafy shoot and flower buds used as tea in China. Flowers eaten boiled or fried in Japan	Tanaka (1976), Kunkel (1984), Hu (2005)
<i>Lespedeza davurica</i> (Laxm.) Schindl.	Ox-Bush Clover, Mongolian Lespedeza; Niu Zhi Zi (Chinese); Daguur Khoshonbut (Mongolian)	Flowers and leaves used for tea in China	Hu (2005)
<i>Leucaena leucocephala</i> (Lam.) de Wit	White Leadtree, Lead Tree, Koa HaoLe, Ekoo, Leucaena, Horse Tamarind, Jumbie Bean, White Popinac, Jumbay	Flowers eaten in Thailand	Kaisoon et al. (2011)
<i>Leucaena glauca</i> (Willd.) Benth. = <i>Leucana leucocephala</i> (Lam.) de Wit	White Leadtree, Lead Tree, Koa HaoLe, Ekoo, Leucaena, Horse Tamarind, Jumbie Bean, White Popinac, Jumbay	Flower buds eaten in salad and cooked as vegetable	Ochse and van den Brink (1980)
<i>Lysiphyllum carronii</i> (F. Muell.) Pedley	Red Bauhinia, Queensland Ebony, Northern Beantree, Carrons Bauhinia	Nectar sucked from flowers	Cribb and Cribb (1987)
<i>Lysiphyllum gilvum</i> (Bailey) Pedley	Bauhinia Tree, Queensland Bean Tree, Bohemia	Flower pounded, mixed with honey and fermented to make an intoxicating drink. Nectar sucked from flowers or soaked in water to make drinks	Low (1991)
<i>Lysiphyllum hookeri</i> (F. Muell.) Pedley	Bauhinia, White; Bauhinia; Pegunny; Ebony, Mountain; Ebony, Queensland; Hooker's Bauhinia; Mountain Ebony; White Bauhinia; Queensland Ebony; Bauhinia	Nectar sucked from flowers	Cribb and Cribb (1987)

<i>Medicago polymorpha</i> L.	California Burclover, Toothed Bur Clover, Toothed Medick, Burr Medic	Flowers eaten raw in salad or cooked as potherb, stir-fried or used in soups	Tanaka (1976), Facciola (1990)
<i>Medicago sativa</i> L.	Alfalfa, Spanish Clover, California Clover, Buffalo Herb, Lucerne, Purple Medic	Flower heads blended with red clover and spearmint or peppermint and brewed into tea	Clarke (1977), Facciola (1990)
<i>Melilotus alba</i> Ledeb. = <i>Melilotus officinalis</i> subsp. <i>alba</i> (Medik.) H. Ohashi and Tateishi	White Melilot, White Sweet Clover	Flowers eaten raw or cooked and used as a vanilla-like flavouring	Kunkel (1984), Facciola (1990)
<i>Melilotus officinalis</i> (L.) Pall.	Melilot, Yellow Sweet Clover, Yellow Melilot, Ribbed Melilot, Common Melilot	Flowers eaten raw or cooked. The flowers and seeds are used as a flavouring. Flower tops are dried and used to scent and flavour sausages and stuffings like rabbit, marinades and beers	Hedrick (1972), Schofield (2003), Garland (1993)
<i>Mimosa pudica</i> L.	Sensitive Plant, Touch-Me-Not, Humble Plant, Shameful Plant; Sleeping Grass, Ant Plant	Flowers crystallized or used for the preparation of distilled flower water	Crowhurst (1972), Facciola (1990)
<i>Mucuna pruriens</i> (L.) DC.	Velvet Bean, Cowitch, Cowhage, Kapikachu		King (2007)
<i>Ononis spinosa</i> L.	Spiny Rest Harrow, Rest Harrow	Flowers eaten raw and used as a decoration on salads	Chiej (1984)
<i>Parkia timoriana</i> (DC.) Merr.	Tree Bean; Yongchak (Manipur)	Young inflorescences and pods eaten	Yunnum and Tripathi (2012)
<i>Phaseolus coccineus</i> L.	Scarlet Runner Bean, Runner Bean, Dutch Runner Bean, Case Knife Bean, Seven Year Bean	Flowers can be eaten raw in salads, adding a mild bean flavour with a hint of nectar, or added to cooked runner bean dishes for decoration	Kunkel (1984), Facciola (1990), Lauderdale and Evans (1999), Newman and O'Connor (2009), Anonymous (2012a), Deane (2007–2012j)
<i>Phaseolus vulgaris</i> L.	Green Beans, Common Bean, Kidney Bean, String Bean, Garden Bean, Field Bean, Haricot	Flowers are edible	King (2007)
<i>Pisum sativum</i> L.	Garden Pea, English Pea, Green Pea, Snap Pea, Sweet Pea, Snow Pea	Flowers are edible raw in salad and have a fresh pea taste	Newman and O'Connor (2009), Deane (2007–2012m)
<i>Psophocarpus tetragonolobus</i> (L.) DC.	Four-Angled Bean, Goa Bean Winged Bean, Princess Bean	Flowers and buds eaten in salads, steamed or batter-fried like tempura, spicy stir-fry or dip in a sambal (spicy chili) paste	Ochse and van den Brink (1980), Facciola (1990), Khan (1994), Woodward (2000), Saidin (2000)
<i>Pterocarpus indicus</i> Willd.	Rosewood, Angsana, Sena, Narra, New Guine Rosewood	Flowers used in salad and other dishes	King (2007)
<i>Pterocarpus marsupium</i> Roxb.	Indian Kino Tree, Malabar Kino, Kino	Seeds and flowers eaten in India (Deccan)	Watt (1908)

<i>Pueraria lobata</i> (Willd.) Ohwi = <i>Pueraria montana</i> (Lour.) Merr. var. <i>lobata</i> (Willd.) Maesen and S.M. Almeida	Kudzu, Kudzu Vine; Ge Gen (Chinese)	Flower and buds used as ingredient in five-flower tea 'wu-hua cha'. Flowers used as vegetables cooked or made into jellies or pickles	Hu (2005), Groen et al. 1996, Fernald et al. (1958), Facciola (1990), Deane (2007–2012k, z)
<i>Robinia hispida</i> L.	Rose Acacia, Britisly Locust, Rose Locust	Flowers edible	McVicar (2003)
<i>Robinia luxurians</i> (Dieck.) Schneid.		Flowers edible raw	Tanaka (1976)
<i>Robinia neomexicana</i> A. Gray	New Mexican Locust	Pink flowers eaten raw without preparation or cooked	Yanovsky (1936), Tanaka (1976), Facciola (1990), Moerman (1998)
<i>Robinia pseudoacacia</i> L.	Black Locust, Foreign Pagoda Tree; Yang Huai (Chinese)	Washed flower mixed with flour, steamed, seasoned and eaten in northern China. Flowers dipped into egg batter and fried, added to pancake batter or made into a pleasant drink	Fernald et al. (1958), Crowhurst (1972), Facciola (1990), Hu (2005)
<i>Saraca bijuga</i> Prain = <i>Saraca indica</i> L.	Ashoka Tree; Sok Nam (Thai); Gapis, Tengalan (Malay)	Flowers are sour and used as potherb	Burkill (1966), Tanaka (1976), Pongpangan and Poobarasert (1985), Facciola (1990), Wessapan et al. (2007)
<i>Saraca indica</i> L.	Ashoka Tree; Sok Nam (Thai); Gapis, Tengalan (Malay)	Flowers eaten in Thailand	Van den Bergh (1994b), Wetitayaklung et al. (2008)
<i>Sarothamnus scoparius</i> (L.) W.D.J. Koch = <i>Cytisus scoparius</i> (L.) Link	Broom, Genista, Irish Broom, Scotch Broom	Flower buds are added to salads, made into wine or pickled in vinegar and used like capers	Grieve (1971), Hedrick (1972), Facciola (1990)
<i>Schotia capitata</i> Bolle	Dwarf Boer-Bean	Flower nectar sucked	Facciola (1990)
<i>Senna siamea</i> (Lam.) Irwin and Barneby	Bombay Blackwood, Kassod Tree	Flowers eaten as food	Wetitayaklung et al. (2008)
<i>Sesbania aegyptiaca</i> Poir. = <i>Sesbania sesban</i> (L.) Merr.	Common Sesban, Egyptian Rattle Pod, Frother, River Bean, Sesban, Sesbania, Egyptian Sesban	Flowers of a wild and sometimes cultivated species eaten in West Africa. Flowers eaten fried with pounded rice or gram	Irvine (1952), Patri and Borah (2007)
<i>Sesbania bispinosa</i> (Jacq.) W. Wright	Prickly Sesban, Spiny Sesbania	Flowers edible	Burkill (1966), Tananka (1976), Facciola (1990)

<i>Sesbania grandiflora</i> (L.) Pers.	Scarlet Wisteria Tree, Vegetable Humming Bird Vegetable Hummingbird (English), Shiro Gocho (Japanese)	Flowers, young fruits, young leaves and pods cooked as vegetables. Pistil removed first In Thailand, the shoots and young leaves are blanched and eaten with 'nam phrik', as are the flowers after the removal of the bitter stamens. The flowers can also be used in 'kaeng som' (sweet and sour curry), fried with pork or prawns or mixed with flour and fried. In Assam, flowers are fried and eaten with pounded rice or gram	Ochse and van den Brink (1980), Pongpangan and Poobarasert (1985), Facciola (1990), Rojanpo and Tepsuwan (1992), Kusamaran et al. (1998), Woodward (2000), Weitayaklung et al. (2008), Hu (2005), Tanaka and Nguyen (2007), Patiri and Borah (2007), Jircas (2010)
<i>Sesbania javanica</i> Miq.	Sesbania-Pea; Sano Kin Dok, Phak Hong Haeng, Si Pree Laa, Sano Hin (Thai)	The young shoots are cooked and eaten with 'nam phrik'. The flowers are eaten either raw, blanched, fried with egg or fermented and are served with nam 'phrik kapi'. Because the flowers contain a carotenoid substance, they are used to give a yellow colour to various desserts such as 'kanom bua loi', which are coloured balls of sticky rice flour cooked in sweetened coconut milk	Tanaka and Nguyen (2007), Weitayaklung et al. (2008), Jircas (2010)
<i>Sesbania roxburghii</i> Merr. = <i>Sesbania javanica</i> (Miq.)	Sesbania-Pea; Sano Kin Dok, Phak Hong Haeng, Si Pree Laa, Sano Hin, Sa No (Thai)	Flowers eaten raw or cooked	Pongpangan and Poobarasert (1985)
<i>Sesbania sesban</i> (L.) Merr.	Common Sesban, Egyptian Rattle Pod, Frother, River Bean, Sesban, Sesbania, Egyptian Sesban	In Nigeria (northern Kano State), flowers and fruits eaten. In Assam, flowers fried and eaten with pounded rice or gram	Dalziel (1937), Tanaka (1976), Mortimore (1989), Facciola (1990), Patiri and Borah (2007)
<i>Sophora viciifolia</i> Hance = <i>Sophora davidii</i> (Franch.) Pavol. <i>Sophora davidii</i> (Franch.) Pavol.	Shrub Pagoda Tree, David's Mountain Laurel; Lang Ya Ci (Chinese) Shrub Pagoda Tree, David's Mountain Laurel	Flowers eaten in China Flowers eaten in China	Hu (2005) Altschul (1973), Tanaka (1976), Facciola (1990)
<i>Sophora japonica</i> L. = <i>Styphnolobium japonicum</i> (L.) Schott.	Japanese Pagoda Tree, Pagoda Tree, Chinese Scholar Tree Yellow Berry, Pagoda Tree	Flower and buds used as ingredient in five-flower tea called 'wu-hua cha' in China and also eaten as food	Read (1946), Altschul (1973), Tanaka (1976), Facciola (1990), Hu (2005)
<i>Tamarindus indica</i> L.	Tamarind	Tree usually grown for its fruit. Young shoots and flowers are eaten as vegetable. The sour taste enhances the taste of many kinds of curries. In western Rajasthan, the leaves, fruits and flowers are eaten. In Nigeria (Kano State, northern), the pods, leaves, fruits, seeds and flowers eaten raw in salads or cooked	Gammie (1902), Tanaka (1976), Ochse and van den Brink (1980), Morton (1987), Mortimore (1989), Facciola (1990), Woodward (2000), Jircas (2010), Lim (2012b)

<i>Trifolium fucatum</i> Lindl.	Sour Clover, Bull Clover, Puff Clover	Flowers and young seedpods eaten raw or cooked	Moerman (1998)
<i>Trifolium hybridum</i> L.	Alsike Clover, Hybrid Clover	Flowers sucked for nectar, added to soup, dip in batter and fry as fritters. Flower heads dried make into tea	Peterson (1977), Facciola (1990), Schofield (2003)
<i>Trifolium incarnatum</i> L.	Crimson Clover, Italian Clover, French Clover	Flower heads steep for brew and tea	Peterson (1977), Facciola (1990)
<i>Trifolium involucreatum</i> Orteg. = <i>Trifolium mucronatum</i> subsp. <i>mucronatum</i> Willd. ex Spreng.	Cusp Clover	Flowers eaten in California	Yanovsky (1936)
<i>Trifolium pratense</i> L.	Red Clover, Beebread, Cow Clover, Cow Grass, Meadow Clover, Purple Clover, Wild Clover.	Flower heads steep for brew, wines and pickles; young flowers used as sandwich filling; flowers sucked for nectar, added to soup, dip in batter and fry as fritters; flower head dried, powdered and sprinkled on boiled rice	Tanaka (1976), Cribb and Cribb (1987), Low (1989), Barash (1997), Lauderdale and Evans (1999), Facciola (1990), Roberts (2000), Schofield (2003), Newman and O'Connor (2009)
<i>Trifolium repens</i> L.	White Clover, Dutch White Clover	Flower heads steeped for brew, wines and pickles; young flowers used as sandwich filling; flowers sucked for nectar	Fernald et al. (1958), Hedrick (1972), Cribb and Cribb (1987), Low (1989), Facciola (1990), Schofield (2003)
<i>Trifolium variegatum</i> Nutt.	Whitetail Clover	Flowers eaten raw and have a sweet flavour	Moerman (1998)
<i>Trifolium virescens</i> Greene = <i>Trifolium fucatum</i> Lindl.	Sour Clover, Bull Clover, Puff Clover	Flowers eaten in California	Yanovsky (1936)
<i>Ulex europaeus</i> L.	Furze, Gorse, Common Gorse	Buds pickled in vinegar and eaten in salads Flowers are a trailside nibble. They can be added to salads, made into tea or used to flavour wine. Oddly, the blossoms smell slightly of coconut but taste like almonds. The bright flowers have also been used for dye, Easter eggs to clothes	Low (1989), Deane (2007–2012y), Grieve (1971), Facciola (1990)
<i>Vicia cracca</i> L.	Tufted Vetch, Cow Vetch, Bird Vetch, Boreal Vetch, Shao Cai (Chinese)	Young shoot including flower buds cooked fresh or dried for winter use in China	Hu (2005)
<i>Vigna luteola</i> (Jacq.) Benth.	Hairy Cowpea, Hairypod Cowpea, Dalrymple Vigna, Deer Pea	Flowers edible cooked	Deane (2007–2012r)

<i>Vigna umbellata</i> (Thunb.) Ohwi and H. Ohashi	Rice Bean, Red Rice Bean	Flowers eaten	King (2007)
<i>Vigna unguiculata</i> subsp. <i>sesquipedalis</i> (L.) Verdc.	Snake Bean, Long Bean Yardlong Bean	Flowers used in spicy stir-fry or cooked in creamy coconut	Saidin (2000)
<i>Wisteria floribunda</i> (Willd.) DC.	Japanese Wisteria	Flowers cooked as food in parts of China	Tanka (1976), Kunkel (1984), Facciola (1990), Deane (2007–2012)
<i>Wisteria frutescens</i> (L.) Poir	American Wisteria	The fresh flowers are eaten in tossed green salads. Flowers also excellent when dipped in batter and fried in oil as fritters	Fernand et al. (1958), Peterson (1977), Facciola (1990)
<i>Wisteria sinensis</i> (Sims) Sweet	Wisteria, Chinese Wisteria; Zi Teng Hua (Chinese)	Flowers and buds washed, mixed with flour, steamed, seasoned and eaten in northern China. Flowers also thoroughly boiled and eaten with oil and salt. The flowers are a common addition to cakes around Peking. Flowers folded into egg batter and made into fritters. Flowers also used for preserves or brewed into wine	Read (1946), MacNicol (1967), Tanaka (1976), Facciola (1990), Hu (2005), Deane (2007–2012)
<i>Wisteria villosa</i> Rehder	Wooly Wisteria	Flowers edible	Tanaka (1976), Kunkel (1984)
Fagaceae			
<i>Castanopsis hystrix</i> Miquel = <i>Castanopsis purpurella</i> subsp. <i>purpurella</i>	Hong Zhui (Chinese)	Catkins eaten	Kunkel (1984)
<i>Fagus grandifolia</i> Ehrh.	American Beech, Beech, Carolina Beech, Gray Beech, Red Beech, Ridge Beech, Stone Beech, White Beech, Winter Beech	Swelling flower buds used for food	Yanovsky (1936)

species dealt with in this volume include both lesser-known, wild and underutilized plants and also common and widely grown ornamentals.

As in the preceding 6 volumes, topics covered include the following: taxonomy (botanical name and synonyms), common English and vernacular names, origin and distribution, agroecological requirements, edible plant part and uses, plant botany, nutritive and medicinal/pharmacological properties with up-to-date research findings and traditional medicinal uses, other nonedible uses and selected/cited references for further reading.

Use of Edible Flowers

Since antiquity right through the Middle Ages and the seventeenth century, flowers have been featured as an integral part of human nutrition in Europe—ancient Rome, medieval France, Victorian England, Middle East—and in Asia particularly in China, India, Thailand and Japan. Flowers have long been used as decorations in food prepared for the nobility. Today, consumption of edible flowers is increasing worldwide (Milcek and Rop 2011; Rop et al. 2012). Edible flowers are becoming more popular as evidenced by the profusion of edible flower cookbooks, culinary magazine articles, scientific papers on edible flowers and television shows. Flowers are consumed in various forms, colours and flavours to enhance the nutritional and sensory qualities of foods. Its qualities, freshness and safety depend on the care taken in its harvesting and storage. Many of the lesser-known edible flowers are harvested in the wild from plants in the forest, wasteland, disturbed sites, near waterways and roadside often occurring as weeds (*Limncharis*, milkweeds, beggarticks, dandelion, *Acacia* spp.). In contrast many of the commonly known edible flowers (e.g. roses, chrysanthemums, carnations, marigolds, daylilies, cornflower) are harvested from cultivated garden ornamentals or culinary herb garden (e.g. chives, *Mentha* spp. borage, rosemary, chamomile).

Edible flowers can be used raw or fresh as a garnish or as an integral part of a dish, such as a vegetable or fruit salad. Today, many restaurant

chefs and innovative home cooks garnish their entrees with flower blossoms for a touch of elegance. Many flowers can be fried in light batter or cornmeal, e.g. squash, zucchini flowers or in fritters (e.g. *Acacia* blossoms). Some flowers can be steamed, boiled, grilled or used in soups and curries. Some flowers can be stuffed or used in stir-fry dishes. Edible flowers can be crystallized, candied; frozen in ice cubes and added to beverages; made into jellies and jams; used to make teas or wines; to flavour liquors, vinegar, oil, honey and scented sugars; added to punch, cocktail and other beverages; and minced and added to cheese spreads, herbal butters, pancakes, crepes and waffles. Many flowers can be used to make vinegars for cooking, marinades or dressings for salads.

Some important rules on the use of edible flowers:

- Flowers have to be accurately identified before eating.
- Do not eat flowers from florists, nurseries, garden centres, fruit orchards or flowers from plants found on the side of the road and in murky waterways because of possible contamination from pesticide sprays, vehicle carbon emissions and industrial and effluent run-off.
- Harvest/pick flowers that are free from diseases, insects, insect damage and soil particles.
- Pick young fresh flowers and buds on dry mornings, before the sun becomes too strong, to retain the bright colours and intense flavours.
- Use flowers immediately for best results or refrigerate in a plastic bag for a few days. Dried, frozen or freeze-dried flowers are best used in infusions or cooked.
- For medium and large flowers like hollyhocks, roses, lilies, calendula, chrysanthemum, lavender, rose, tulip, yucca, hibiscus, lavender, tulip and marigolds, use only the petals and discard stamens, pistil and calyx. The bitter ‘heel’ at the base of the petal should be removed.
- Eat edible flowers in moderation.
- People with hay fever, asthma or allergies should best avoid eating flowers since many allergies are due to sensitivity to pollen of specific plants.

Nutrients and Bioactive Phytochemicals in Flowers

Nutrients and phytochemicals contained in flowers are not markedly different from those found in other plant organs (leaves, stem fruit). Several thousands of compounds have been identified in flowers including nutrients (proteins, carbohydrates, lipids, fibre, minerals, fatty acids, vitamins and essential amino acids), flavonoids, carotenoids, anthocyanins and other phenolic compounds, waxes, resins in the floral parts (petals, sepals, pollens, etc.), in the floral nectar, as fragrance volatiles, and essential oil components monoterpenes, sesquiterpenes esters, alcohols (monoterpene and sesquiterpene alcohols), aldehydes, ketones, phenols, alkanes, esters, lactones, coumarins, ether, oxides, fatty acids, fatty acid derivatives, benzenoids, phenylpropanoids, isoprenoids and nitrogen- and sulphur-containing compounds (Mookherjee et al. 1990; Knudsen et al. 1993; Dobson et al. 1997; Kim et al. 2000; Falzari and Menary 2003; Kaisoon et al. 2011; Mlcek and Rop 2011; Rop et al. 2012; Diraz et al. 2012). The concentrations of these compounds vary throughout the development and maturation of the flower and also during storage after harvesting. Health benefits attributable to antioxidant capacity have been shown to be highly correlated with phenolic compounds (Kaisoon et al. 2011; Rop et al. 2012).

Flower Pollen

The composition of pollen changes from floral species to species, variation in absolute amounts of the different compounds can be very high. The major components of pollens are proteins and amino acid, lipids (fats, oils or their derivatives) (Manning 2001), and sugars (Crane 1990); the nutrient profile in dried bee-collected pollen and dried hand-collected pollen are as follows: water, 11 %, 10 %; crude protein, 21 %, 20 %; ash, 3 %, 4 %; crude fats, 5 %, 5 %; reducing sugars, 26 %, 3 %; nonreducing sugars, 3 %, 8 %; starch, 3 %, 8 %; and undetermined components, 29 %, 43 %, respectively. The minor components of bee-

collected pollens are more diverse (Crane 1990): flavonoids at least 8; carotenoids (at least 11); vitamins C, E B complex (including, niacin, biotin, pantothenic acid, riboflavin (B₂) and pyridoxine (B₆)); minerals—macro-elements (K, Na, Ca, Mg, P, S) and micro-elements (Al, B, Cl, Cu, I, Fe, Mn, Ni, Si, Ti and Zn); all free amino acids; terpenes; nucleic acids DNA, RNA and others; enzymes >100; growth regulators auxins, brassins, gibberellins and kinins; and growth inhibitors. All amino acids essential to humans (phenylalanine, leucine, valine, isoleucine, arginine, histidine, lysine, methionine, threonine and tryptophan) can be found in pollen and most others as well, with proline being the most abundant. Most simple sugars in pollen comprise fructose, glucose and sucrose come from the nectar or honey of the field forager. The polysaccharides like callose, pectin, cellulose, lignin, sporopollenin and others are predominantly pollen components. Protein contents of above 40 % have been reported, but the typical range is 7.5–35 %: typical sugar content ranges from 15 to 50 %, and starch content is very high (up to 18 %) in some wind-pollinated grasses (Schmidt and Buchmann 1992). Low lipid levels (0.6–1.9 % dry mass) are found in bee-collected pollen of eucalypts (Bell et al. 1983; Manning and Harvey 2002), whereas an high level of 32 % dry mass is found for canola pollen by Evans et al. 1987. Pollen has been added to diets for domestic animals and laboratory insects resulting in improvements of health, growth and food conversion rates (Crane 1990; Schmidt and Buchmann 1992).

Floral Nectar

The nectar is a liquid with a sweet taste, comprising sugars, amino acids, nonprotein amino acids, proteins, minerals, lipids, organic acids, phenolic compounds, alkaloids, coumarins, saponins, terpenoids, etc. (Nicolson and Thornburg 2007). The major sugars in nectar are the disaccharide sucrose and the hexose monosaccharides glucose and fructose (Baker 1975; Baker and Baker 1983). Bernadello et al. (1999) found that the floral nectar of 29 species native to Argentinian Patagonia to be hexose dominant (72.41 %) or

hexose rich (17.24 %); a few were sucrose dominant (10.34 %). Though a large majority of floral nectars is dominated by sucrose, glucose and fructose, the pentose sugar xylose is a major nectar sugar in *Protea* and *Faurea*, two related genera of the Proteaceae (Nicolson and van Wyk 1998). Other minor sugars present in trace amounts in nectar include monosaccharides (e.g. mannose, arabinose, xylose), disaccharides (maltose, melibiose) or, more rarely, oligosaccharides (raffinose, melezitose, stachyose) (Baker and Baker 1982a, 1983; Nicolson and Thornburg 2007). Sorbitol is also a frequent constituent of Mediterranean nectars (Petanidou 2005). Minerals have been found in floral nectar (Hiebert and Calder 1983; Heinrich 1989). Potassium was found to be the dominant ion with 35–74 % in nectars; the other cations can be listed up according to their decreasing amounts: Na, Ca, Mg, Al, Fe and Mn (Heinrich 1989). Although all ten essential amino acids are commonly present in floral nectars as free amino acids, some nonessential amino acids such as asparagine and glutamine can occur in much higher concentrations (Nicolson and Thornburg 2007). The presence of amino acids in floral nectars was first reported by Ziegler (1956), later by Lüttge (1961, 1962) and Baker and Baker (1973, 1977, 1986). In *Erythrina* species pollinated by passerine birds, the total amino acid concentrations are far higher than in hummingbird-pollinated species (Baker and Baker 1982b). Few of the nontoxic nonprotein amino acids, including β -alanine, ornithine, homoserine and γ -aminobutyric acid (GABA), are known to accumulate in nectar (Nicolson and Thornburg 2007). The existence of proteins in nectar has been reported long ago (Pryce-Jones 1944; Lüttge 1961). The first enzymatic activity to be identified in nectar was invertase, found in the floral nectar of *Tilia* sp. (Beutler 1935). Other proteins identified in various floral nectars included the following: *trans*-glucosidase in *Robinia pseudoacacia* (Zimmerman 1953); *trans*-fructosidase in *Impatiens holstii* (Zimmerman 1954); phosphatase (Cotti 1962); tyrosinase in *Lathraea clandestina* (Lüttge 1961); mannose-binding lectin and alliinase in *Allium porrum*

(Peumans et al. 1997); and nectarin IV (Naqvi et al. 2005) and nectarin I, II, III and V in *Nicotiana* sp. (Carter and Thornburg 2000; 2004a, b).

The presence of lipids has been reported in numerous floral nectars (Vogel 1971; Baker and Baker 1975; Bernardello et al. 1999). Some major lipids found in floral nectars of *Calceolaria* species (Scrophulariaceae) and in the rhattanys (*Krameria* species, Zygophyllaceae) included β -acetoxo fatty acids of varying chain length between C16 and C20 (Vogel 1971; Seigler et al. 1978). Ascorbic acid (vitamin C) is well known as an antioxidant in floral nectar (Baker and Baker 1975). Phenolic substances are quite widespread in nectars (Baker and Baker 1982a; Gil et al. 1995; Ferreres et al. 1996). European *Eucalyptus* honeys were found to have the following flavonoids: myricetin, quercetin, tricetin, luteolin and kaempferol (Martos et al. 2000) and *Robinia pseudoacacia* flowers to have nectar flavonol rhamnosides as floral markers (Truchado et al. 2008). Alkaloids and allelochemicals have been detected in the nectar of a large number of plants (Hazslinsky 1956; Baker and Baker 1975; Galetto and Bernardello 1992; Detzel and Wink 1993; Adler and Wink 2001). Recently, Singaravelan et al. (2005) reported four secondary alkaloid compounds occurring naturally in floral nectar: nicotine, anabasine, caffeine and amygdalin in many plants including *Nicotiana* spp. and *Tilia cordata* (Singaravelan et al. 2006). While terpenoids do occur in plant nectars (Detzel and Wink 1993), most are produced by cells with specialized metabolic potential that are dispersed throughout the flower (Bergström et al. 1995; Dudareva et al. 1998; McTavish et al. 2000).

Tulbaghia violacea

Scientific Name

Tulbaghia violacea Harv.

Synonyms

Omentaria cepacea (L.f.) Salisb. (inval.), *Omentaria violacea* (Harv.) Kuntze, *Tulbaghia cepacea* var. *maritima* Vosa, *Tulbaghia cepacea* var. *robustior* Kunth, *Tulbaghia violacea* var. *minor* Baker, *Tulbaghia violacea* var. *obtusata* Baker, *Tulbaghia violacea* var. *robustior* (Kunth) R.B. Burb

Family

Amaryllidaceae, also placed in Alliaceae, Liliaceae

Common/English Names

Pink Agapanthus, Society Garlic, Sweet Garlic, Wild Garlic

Vernacular Names

Afrikaans: Wildeknoffel, Wilde Knoffel

Swedish: Tulbaghia

Xhosa: Itswele Lomlambo

Zulu: Isihaga

Origin/Distribution

Society Garlic is native to Natal, Transvaal and the Eastern Cape region in South Africa where it grows in rocky grasslands.

Agroecology

Society Garlic grows best in full sun in a light, well-drained and well-aerated sandy or sandy-loam soils. It tolerates light shade but may not flower much. It requires frequent watering during the growing season but less so during flowering and in the winter months. In winter the root ball should be kept moist with reduced watering. Established plants can survive extended droughts and moderate frosts and light freezes down to -6.7°C .

Edible Plant Parts and Uses

Both the leaves and flowers can be used in salads and other dishes (Facciola 1990; Van Wyk and Gericke 2000; Harris 2004). The edible bulb and leaves have a taste of garlic without the nasty side effect of bad breath. Chopped leaves are used in sauces, soups and salads and as a garnish. The flower buds steeped in vinegar give it a mild garlic flavour and can also be used as a garnish. The Zulus use the leaves and flowers as spinach and as a hot, peppery seasoning with meat and potatoes.

Botany

Society Garlic is a clump-forming herbaceous perennial, 60 cm high by 60 wide (Plates 1 and 2). Its rootstock is an ovoid corm with rhizomatous base, 1.5–2.7 cm long and 1–1.5 cm in diameter. Leaves 8–10, greyish-green, linear, 17–50 cm long, 0.35–0.7 cm wide; apex obtuse; base sheathing grows straight up out of the corm. Scape 39–70 cm long grows up from the centre of the rosette of leaves. Atop the scape sits a large umbel with 8–20 sweet-scented lilac-pink flowers on; pedicels 10–20 mm long arise from the same point (Plates 2 and 3). Flower with a cylindrical perianth tube, 8–10 mm long expanding to six elliptic lobes 6–7 mm long, 1.5–2.8 mm wide, apex acute with slightly in-rolled margin. Corona of three distinct oblong lobes, 2.5–3 mm long, 1–1.5 mm wide with retuse apex; stamens included in perianth tube, upper series 2–2.5 mm below mouth, lower series ± 6 mm from base; anthers 1 mm long; ovary oblong to obovoid, 2.5 mm long, 1.5 mm in diameter; ovules numerous; style 1 mm long, 0.4 mm in diameter; stigma

capitate, small. The fruit, triangular capsules, are grouped into a head, and when ripe, they split to release the flattened, hard black seeds.

Plate 1 Society Garlic foliage

Plate 2 Flowering Society Garlic plant

Plate 3 Society Garlic flowers

Nutritive/Medicinal Properties

Jacobsen et al. (1968) reported the presence of an alkylcysteine sulfoxide lyase and three unidentified S-substituted cysteine sulfoxide derivatives, whereas Burton and Kaye (1992) isolated 2,4,5,7-tetrathiaoctane-2,2-dioxide and 2,4,5,7-tetrathiaoctane from the leaves of *T. violacea*. The amino acid (RSRC)-S-(methylthiomethyl) cysteine-4-oxide was isolated from rhizomes of *Tulbaghia violacea* (Kubek et al. 2002). Its content varied in different parts of the plant (rhizomes, leaves and stems) between 0.12 and 0.24 mg/g fresh weight, being almost equal in the stems and rhizomes. In addition, S-methyl- and S-ethylcysteine derivatives have been detected in minute amounts (<3 µg/g fresh wt) in all parts of the plant. 2,4,5,7-Tetrathiaoctane-4-oxide, the primary breakdown product of the amino acid, was also detected and isolated.

Scientific studies have shown that Society Garlic possesses several biological activities which include antioxidant, antimicrobial, anticancer, antiulcerogenic, antithrombotic and antihypertensive properties.

Antioxidant Activity

The antioxidant capacity (oxygen radical absorbance capacity, ORAC value) and total phenolic content for Society Garlic, *Tulbaghia violacea*, was determined as 1.03 µmol of Trolox equivalents (TE)/g of fresh weight, 7.50 mg of gallic acid equivalents (GAE)/g of fresh weight respectively (Zheng and Wang 2001).

Antihypertensive Activity

Tulbaghia violacea was one of the many active plants with antihypertensive properties as determined by the angiotensin-converting enzyme (ACE) inhibition assay; it contained no tannin (Duncan et al. 1999). *T. violacea* leaves had inhibition levels which were above 50 % (aqueous extract gave 72 % inhibition, ethanol extract exhibited

61 % inhibition), while *T. violacea* roots gave 49 and 27 % inhibition for aqueous and ethanol extracts, respectively, with 25 µg plant extract. This was also confirmed in a recent study. A plant was considered to have potential antihypertensive properties if it inhibited the angiotensin-converting enzyme (ACE) and thus the conversion of angiotensin I to angiotensin II by greater than 50 %, and *T. violacea* was one of eight of 16 plants screened that demonstrated ACE inhibitory activity and satisfied these criteria (Ramesar et al. 2008). *T. violacea* in particular showed promise with regard to ACE inhibition as in-vivo administration of this extract showed only a 2.2 % increase in maximum mean arterial pressure when compared to the 14.5 % increase observed in the control group after coadministration with exogenous angiotensin I. Hypertension is treated with medication, including drugs such as angiotensin-converting enzyme inhibitors (ACEI) and angiotensin II receptor blockers (ARB). These drugs not only lower blood pressure but also offer additional protection to the brain and heart. ACEI, in particular, provides beneficial properties to patients with type 1 diabetes.

The methanol leaf extract of *Tulbaghia violacea* significantly and dose-dependently reduced the systolic, diastolic, and mean arterial blood pressure and heart rate in male spontaneously hypertensive Wistar rats (Raji et al. 2012). Angiotensin I human acetate salt hydrate (ang I, 3.1–100 µg/kg), angiotensin II human (ang II, 3.1–50 µg/kg), phenylephrine hydrochloride (phenylephrine, 0.01–0.16 mg/kg) and dobutamine hydrochloride (dobutamine, 0.2–10.0 µg/kg) all increased the blood pressure dose-dependently. The hypertensive effect of ang I and the heart rate-increasing effect of dobutamine were significantly decreased by their co-infusion with *T. violacea* (60 mg/kg). However, the co-infusion of ang II or phenylephrine with *T. violacea* (60 mg/kg) did not produce any significant change in blood pressure or heart rate when compared to the infusion of either agent alone in the same animal. The reduction in blood pressure may be due to actions of the *T. violacea* methanol leaf extract on the angiotensin-I-converting enzyme (ACE) and β(1) adrenoceptors.

Anti-atherosclerotic Activity

Co-treatment of rats with an atherosclerogenic (Ath) diet (4 % cholesterol, 1 % cholic acid and 0.5 % thiouracil) and *Tulbaghia violacea* methanolic rhizome extracts (250 and 500 mg/kg body weight) for 2 weeks significantly protected against elevated serum triglyceride (TG), total cholesterol (TC), LDL-cholesterol, VLDL-cholesterol and decreased HDL-cholesterol in a dose-dependent manner when compared with the atherogenic control (Olorunnisola et al. 2012). The extracts also lowered elevated thiobarbituric reacting substance (TBARS) and reversed endothelial dysfunction parameters (fibrinogen and total NO levels) and tissue anti-oxidant enzyme activities to near normal. The protective ability of the extract was confirmed by the significant reduction in the activities of serum markers of liver (LDH, AST, ALT, ALP, bilirubin) and kidney damage (creatinine and bilirubin) in extract-treated groups compared with the atherogenic control group. Also, the extracts protected against the development of fatty streak plaques (aorta) and fatty changes in hepatocytes. The observed activities of the extracts compared favourably with standard drug atorvastatin. The results showed that the methanol extract of *Tulbaghia violacea* rhizomes could protect against the early onset of atherosclerosis.

Anticancer Activity

Methanol extracts of *Tulbaghia violacea* leaves and bulbs inhibited growth of MCF-7, WHCO3, HT29 and HeLa cancer cell lines (Bungu et al. 2006). At 250 µg/ml, bulb extracts exhibited higher growth inhibition than leaf extracts in MCF-7 (49.6 %), HT29 (26.0 %) and HeLa cells (54.7 %) relative to untreated controls. In WHCO3, the leaf extract was more active, inhibiting growth by 30.3 %. The growth inhibitory activity of *T. violacea* was due to induction of apoptosis in all four cell lines. This was shown by the staining of cells with Hoechst 33342, indicating fragmented nuclear material and condensed

chromatin. HeLa and MCF-7 cells treated with bulb extract had higher apoptotic indices than the other two cell lines (HeLa, 25.8 %; MCF-7, 19.0 %). Treated cells stained with annexin V but not with propidium iodide (PI), indicating that the extract induced apoptosis and not necrosis. Using Western blotting, cleavage of poly[ADP-ribose] polymerase-1 (PARP-1) was shown in HeLa cells upon exposure to *T. violacea* bulb extract. These findings provide evidence for anticancer activities in *T. violacea*. The induction of apoptosis by the extract is promising for anticancer therapy as it is desirable for anticancer agents to induce apoptosis. The occurrence of morphological and biochemical changes, typical of apoptosis, in Chinese hamster ovary (CHO) cells treated with the aqueous extract from *T. violacea* was demonstrated (Lyantagaye 2013). Three proapoptotic fractions from the *T. violacea* extract were purified, and methyl- α -D-glucopyranoside was found to be the major component. Methyl- α -D-glucopyranoside was confirmed to be active in the induction of apoptosis.

Antimicrobial Activity

Gaidamashivili and Van Staden (2001) reported *T. violacea* to have antibacterial activities against two Gram-positive bacterial pathogens *Staphylococcus aureus* and *Bacillus subtilis*. *B. subtilis* was aggregated by *Tulbaghia violacea* agglutinins at relatively high concentrations. *Tulbaghia violacea* bulb extract was found to be inhibitory to *Candida albicans*, pathogen of oral candidiasis, which is prevalent in HIV patients, exhibiting an MIC value of 3.25 mg/ml (Motsei et al. 2003). The freshwater extract of *Tulbaghia violacea* maintained activity at 4 °C, but not at higher temperatures.

Methanol extracts (5 mg/100 ml) of *Tulbaghia violacea* showed little free radical scavenging activity against DPPH (29 %) and ABTS (20 %) and exhibited a low reducing power (Ntobaki et al. 2008). However, the extract significantly inhibited the activities of lipoxxygenase, xanthine oxidase and other lipid-peroxidative reactions.

Plant extracts exhibited antimicrobial activities against *Staphylococcus aureus*, *Proteus mirabilis* (MIC value <1.0 mg/ml), *Streptococcus faecalis*, *Enterobacter cloacae*, *Escherichia coli*, *Proteus vulgaris* and *Helicobacter pylori* (MIC value=2.0 mg/ml). The extract was able to protect the stomach lining against indomethacin-induced ulceration. They concluded that *Tulbaghia violacea* root extract had little hydrogen atom donor potential and may not break free radical chain reactions but could act as an antioxidant. Its potential in the inhibition of free radical generation, along with its antimicrobial activity, justified its use by traditional Zulu healers for the treatment of peptic ulcers and other stomach ailments.

Tulbaghia violacea and *Tulbaghia alliacea* were found to be rich in marasmin, the precursor of the thiosulfinate marasmicin (Kusterer et al. 2011). Marasmicin has attracted considerable attention because of its antifungal and tuberculostatic activities. Somai and Belewa (2011) found that the aqueous extracts of *Tulbaghia violacea* were antifungal and at 10 mg/ml resulted in sustained growth inhibition of greater than 50 % for both *Aspergillus flavus* and *Aspergillus parasiticus*. *T. violacea* extract inhibited conidial germination in a dose-dependent manner.

The petroleum ether (PE) extracts of micropropagated *T. violacea* plants and dichloromethane (DCM) extracts of outdoor-grown plants showed good antibacterial activity against *Bacillus subtilis*, *Escherichia coli*, *Klebsiella pneumoniae* and *Staphylococcus aureus* (Ncube et al. 2011). PE extracts of micropropagated plants showed the best antibacterial activity with a minimum inhibitory concentration (MIC) of 0.39 mg/ml against *Bacillus subtilis*. Good MIC (<1 mg/ml) and minimum fungicidal concentration (MFC) values of 0.78 mg/ml were only obtained in DCM extracts of outdoor-grown plants against *Candida albicans*. MIC and MFC values for water and ethanol extracts of both micropropagated and outdoor-grown plants were similar and in the range 3.125–12.5 mg/ml. Total phenolics, gallotannins, flavonoids and saponins were significantly higher in micropropagated

plants than in outdoor-grown ones. In all cases, the contents of phytochemical compounds in micropropagated plants were more than twice that of outdoor-grown plants except for condensed tannins.

Antithrombotic Activity

The bulb and leaf extracts of *T. violacea* exhibited antithrombotic activities which were higher than those found in garlic (Bungu et al. 2008). The IC₂₀₀ values for the leaf and the bulb extract were 0.4 and 0.3 mg/ml, respectively, for the thrombin-induced clotting time (TT) assay. The IC₅₀ value was 1.73 mg/ml for the bulb extract of the *T. violacea*. No IC₅₀ was obtained for the leaf extract of *T. violacea*. It was also that *T. violacea* exhibited biological activities which were comparable to garlic. These results indicated that *T. violacea* could be used as an alternative to garlic and that it may contribute to pharmaceutical applications and informal health services.

Androgenic Activity

Treatment of male Balb/C mice testicular cells with *Tulbaghia violacea* (312.5–5,000 µg/ml) significantly increased luteinizing hormone (LH)-induced testosterone production as compared to vehicle-treated control (DMSO), whereas testicular cells without LH treatment showed no significant change in testosterone concentrations (Ebrahim and Pool 2010). The data indicated that *T. violacea* had androgenic properties.

Antidiabetic Activity

In an antidiabetic screening of five South African medicinal plants, the ethanol extracts of *Ruta graveolens* (136.9 %) and *Tulbaghia violacea* (140.5 %) produced the highest increase in glucose utilization in C2C12 muscle cells (van Huyssteen et al. 2011).

Traditional Medicinal Uses

Society Garlic is widely used as a herbal remedy for various ailments in traditional medicine, with leaves and bulbs the most commonly used. Its medicinal uses include: treatment for fever and colds, asthma, tuberculosis, high blood pressure, oesophagus cancer, stomach problems such as gastroenteritis, abdominal pain and acute inflammation and sloughing of the intestinal mucosa; and contraction and subdued reaction of the pupils to stimuli (Duncan et al. 1999; van Wyk and Gericke 2000; Gericke et al. 2002; Lyantagaye 2013; Ntobaki et al. 2008). The fresh bulbs are boiled in water, and the decoctions are taken orally to clear up coughs and colds. The bulb has been used as a remedy for pulmonary tuberculosis and to destroy intestinal worms. The leaves of the plant are used to treat oesophageal cancer. Leaves when crushed on the skin will repel fleas, ticks and mosquitoes. Zulus use the bulb to make an aphrodisiac medicine. The crushed leaves may be used to help cure sinus headaches and to discourage moles from the garden (by their strong smell). The smell repels fleas, ticks and mosquitoes when crushed on the skin.

Other Uses

Society Garlic is a popular container plant and is also cultivated in a sunny border, as a bedding plant and in rock garden. It is reported that Society Garlic, planted in a row or border, will deter moles. Wild garlic is a very good snake repellent, and for this reason the Zulus plant it around their homes.

T. violacea has antimicrobial activity against plant pathogens. Crude methanol extracts of *T. violacea* aerial and below-ground parts were found to exhibit antibacterial and broad-spectrum antifungal activity against plant pathogens (Nteso and Pretorius 2006). The extracts significantly inhibited in-vitro growth of *Clavibacter michiganensis*, *Ralstonia solanacearum* and *Xanthomonas campestris*. The extracts significantly inhibited the mycelial growth of six of the seven test fungi, *Botrytis cinerea*, *Sclerotium*

rolfsii, *Rhizoctonia solani*, *Mycosphaerella pinodes*, *Botryosphaeria dothidea* and *P. Pythium ultimum*, whereas only the below-soil extract inhibited the mycelial growth of *Fusarium oxysporum* significantly.

Comments

Society Garlic is most readily propagated via the division of large clumps of plants.

Plumeria obtusa

Scientific Name

Plumeria obtusa L.

Synonyms

Plumeria obtusa var. *typica* Woodson nom. inval.

Family

Apocynaceae

Malaysia: Frangipani, Kemboja

Mexico: Caxtaxanat, Flor De Mayo, Tenech Coahuil

Panama: Caracucho Colorado

Philippines: Kalasuting-Puti

Peru: Caracucho, Suche

Portuguese: Flor-De-Santo-Antônio

Spanish: Alhelí, Alhelí Cimarrón, Suche

Sri Lanka: Araliya

Swedish: Frangipani

Thai: Dtôn Lân Tom KăAo, Dtôn Lân Tom Lôok Pà-Sôn, Dtôn-Lee-Laa-Wá-Dee

Vietnamese: Đại Lá Tù; Đại Lá Tà; SứLá Tù

Common/English Names

Frangipani, Pagoda Tree, Red Jasmine, Red Jasmine of Jamaica, Red Paucipan, Singapore Frangipani, Singapore Graveyard Flower, Singapore White Plumeria, Temple Tree, White Kalachuche

Origin/Distribution

Plumeria obtusa is indigenous to the Greater Antilles, northern Central America and southern-eastern Mexico to Belize, Florida Keys and the Caribbean.

Vernacular Names

Brazil: Jasmim-De-Caiena, Jasmim-Do-Pará, Jasmin-Manga (**Portuguese**)

Chinese: Hong Ji Dan Hua

Cuba: Lirio Colorado

French: Frangipanier

German: Rote Frangipani

India: Kathgolop (**Bengali**), Champa (**Hindi**), Chaempae (**Konkani**), Khageleihao Angouba (**Manipuri**), Arali (**Tamil**)

Agroecology

Though tropical by nature, when protected from frost, they are well suited to subtropical climates in the United States in states bordered by the Gulf of Mexico, and in southern California. They are prolific in Hawaii. Plumeria are valued as landscape plants and ornamentals and for their flowers. Singapore plumeria has larger flowers compared to *Plumeria rubra*, and the longish petals are almost not overlapping. Leaves do not have

pointed ends like *plumeria rubra* and are rather blunt.

Edible Plant Parts and Uses

Edible flowers consumed as vegetable and used as ingredients in cooking salad and frying (Facciola 1990; Wetwitayaklung et al. 2008; Wongwattanasathien et al. 2010; Kaisoon et al. 2001).

Botany

Large shrub or small tree growing to 5 m high. Stem, branches and leaves with milky sap; branches pale-green, thick and fleshy. Leaves alternate, mostly clustered at branch tips, petiole, obovate to oblong-obovate, to 25 cm long, dark green and shiny adaxially, tertiary venation strongly prominent abaxially, apex rounded (Plates 1, 2, 3 and 4). Inflorescence of axillary or terminal dichotomous cymes (Plates 2 and 3). Flowers large, fragrant, waxy and showy with large deciduous bracts. Calyx 5-lobed, lobes equal or subequal. Corolla salverform or funnel shaped, white, 4 cm across, throat yellow, lobes 5, spreading, slightly recurved. Stamens inserted at or near base of corolla tube (Plates 2, 3 and 4). Ovaries 2, distinct; ovules numerous, multiseriate on each placenta. Style short with obtusely bifid apex. Follicles 2. Seeds many, flat proximally, with a membranous wing.

Plate 1 Leaves clustered at branch tips

Nutritive/Medicinal Properties

Flower Phytochemicals

Forty-seven components were identified in the essential oil of fresh *Plumeria obtusa* flowers, representing 97 % of the oil, with benzyl salicylate

Plate 2 Terminal cymose inflorescence

Plate 4 Close view of flowers and leaves

(39 %), benzyl benzoate (11 %), (2*E*, 6*E*)-farnesol (8 %) and (*E*)-nerolidol (5 %) as major constituents (Kamariah et al. 1999). The remaining identified constituents of the oil (34 %) were found as minor constituents (≤ 3 %). Some of the minor components included geraniol, nonadecane, (*E*)-nerolidol, heneicosane, (2*Z*,6*Z*)-farnesol, (2*E*,6*Z*)-farnesol, (2*E*,6*E*)-farnesol, geranyl linalool, neryl benzoate, geranyl benzoate, benzyl benzoate, myristic acid, benzyl salicylate and hexadecanoic acid. The essential oil of *P. obtusa* flower was found to be rich in benzyl salicylate (45.4 %) and benzyl benzoate (17.2 %) (Norsita et al. 2006). Other components were (*E,E*)-farnesol 4.8 %, methyl stearate 3.7 %, neryl phenylacetate 2.6 %, (*E*)-nerolidol 2.5 %, geraniol 2.3 %, ethyl palmitate 2.2 %, 1-octadecene 2.0 % and linalool 1.9 % with minute content of alkanolic acids.

An iridoid beta-glucoside, namely, plumieride coumarate glucoside, and a β -glucosidase were isolated from *P. obtusa* flower (Boonclarm et al. 2006). The β -glucosidase purified to homogeneity exhibited high specificity for its natural substrate, plumieride coumarate glucoside, hydrolyzing it to its corresponding 13-*O*-coumarylplumieride. The enzyme showed poor hydrolysis of 4-methylumbelliferyl- β -glucoside and esculin and did not hydrolyze alkyl- β -glucosides, glucobioses, cyanogenic- β -glucosides, steroid β -glucosides, nor other iridoid β -glucosides.

The soluble phenolic acids (per g dry weight) identified in *P. obtusa* flower extract were gallic acid 25.5 μ g, protocatechuic acid 3.5 μ g, *p*-hydroxybenzoic acid 21.7 μ g, vanillic acid 20.4 μ g, chlorogenic acid 22.8 μ g, caffeic acid 12.8 μ g, syringic acid 7.4 μ g, *p*-coumaric acid 8.3 μ g, ferulic acid 9.8 μ g, sinapic acid 149.3 μ g and total phenolic acid 281.5 μ g (Kaisoon et al. 2001). The flowers contained 329.9 μ g total bound phenolic acid made up of gallic acid 2.7 μ g, *p*-coumaric acid 17.8 μ g, ferulic acid 144.9 μ g, and sinapic acid 164.5 μ g. The flowers contained 702.5 μ g total soluble flavonoid made up of rutin 500.3 μ g, myricetin 5.06 μ g, quercetin 193.6 μ g and kaempferol 3.58 μ g, and bound flavonoid 46.8 μ g made up of 41.7 quercetin μ g and apigenin 5.1 μ g. The DPPH radical scavenging activity (% inhibition) of soluble and bound

phenolic fraction of the flower was 69.65 and 60.52 %, respectively. The reducing potential of the soluble and bound phenolic fractions of the flower as evaluated by FRAP (ferric reducing antioxidant power) assay (mmol FeSO₄/100 g dry weight) were 26.03 and 60.1 mmol, respectively.

The percentage yield of *P. obtusa* flower extracts by water distillation, steam distillation, water-steam distillation, hexane extraction, petroleum ether extraction, and cold and hot enfleurage were 0.0167, 0.0045, 0.0342, 0.4170, 0.3510, 0.3969 and 12.2400 %, respectively (Pitpiangchan et al. 2009). Different extraction methods yielded different chemical compounds and yield. The major chemical components in the essential oils from all distillation methods and both solvents was benzyl salicylate, but the extracts from cold and hot enfleurage were linalool and n-undecanoic acid, respectively. Nineteen compounds were identified in the flower essential oil from water distillation: benzyl salicylate 31.32 %, benzyl benzoate 18.90 %, (*E*)-farnesol 6.70 %, (*Z*)- β -farnesene 4.85 %, linalool 4.72 %, (*E*)-farnesal 4.37 %, (*Z*)-geraniol 4.36 %, (*E*)-geraniol 3.79 %, (*E*)-citral 3.66 %, heneicosane 2.89 %, (*Z*)-farnesol 2.61 %, 1-octadecanol 2.71 %, (*Z*)-citral 2.02 %, α -farnesene 1.97 %, eicosane 1.65 %, (*E*)-farnesyl acetate 1.33 %, 1-hexadecene 1.22 %, (*E*)-farnesyl acetate 0.61 % and 2-methylpentadecane 0.33 %. Thirteen compounds were identified from steam distillation: benzyl salicylate 27.58 %, (*Z*)-geraniol 13.70 %, (*E*)-geraniol 12.15 %, linalool 11.18 %, benzyl benzoate 9.89 %, (*E*)-farnesol 6.95 %; (*Z*)- β -farnesene 4.68 %, (*E*)-citral 4.60 %, (*Z*)-citral 2.54 %, (*E*)-farnesol 2.36 %, α -farnesene 2.27 %, (*Z*)-farnesol 1.41 % and 1-octadecanol 0.69 %. Twenty-one compounds were found in the essential oil from water-steam distillation: benzyl salicylate 31.90 %, benzyl benzoate 13.28 %, (*E*)-farnesol 9.29 %, linalool 6.49 %, (*Z*)- β -farnesene 5.03 %, (*Z*)-geraniol 4.33 %, (*E*)-farnesal 3.42 %, heneicosane 3.20 %, (*E*)-geraniol 3.12 %, (*E*)-citral 3.09 %, 1-octadecanol 3.04 %, α -farnesene 2.62 %, (*Z*)-farnesol 2.14 %, eicosane 1.95 %, unknown2 1.69 %, (*Z*)-citral 1.66 %, 1-hexadecene 1.40 %, (*E*)-farnesyl acetate 1.05 %, unknown1 0.46 %, 2-methylpentadecane 0.45 % and (*E*)- β -farnesene 0.39 %. Hexane extraction afforded

17 compounds: benzyl salicylate 44.69 %, benzyl benzoate 11.67 %, (*E*)-farnesol 7.22 %, (*Z*)-nerolidol 5.53 %, (*Z*)-geraniol 3.93 %, isoeicosane 3.69 %, linalool 3.66 %, (*E*)-geraniol 3.10 %, (*E*)-farnesal 2.84 %, 1-octadecanol 2.80 %, (*E*)-geranylacetone 2.72 %, α -farnesene 2.56 %, (*Z*)-farnesol 1.74 %, unknown2 1.43 %, 1-hexadecene 0.88 %, unknown1 0.84 % and 2,4-di-*t*-butylphenol 0.69 %. Petroleum ether extraction gave 13 compounds: benzyl salicylate 42.63 %, benzyl benzoate 10.64 %, (*E*)-farnesol 9.49 %, (*Z*)-nerolidol 6.53 %, linalool 6.04 %, (*E*)-geraniol 4.44 %, isoeicosane 4.12 %, (*E*)-geranylacetone 3.96 %, α -farnesene 3.39 %, 1-octadecanol 3.33 %, (*E*)-farnesal 2.72 %, (*Z*)-farnesol 1.54 % and 1-hexadecene 1.16 %. Thirteen compound were obtained by cold enfleurage: linalool 23.13 %, benzyl salicylate 15.62 %, benzyl benzoate 14.73 %, (*E*)-farnesal 9.04 %, (*Z*)- β -farnesene 8.16 %, (*Z*)-geraniol 8.31 %, (*E*)-geraniol 4.69 %, (*Z*)-farnesol 4.67 %, (*E*)-citral 4.14 %, (*E*)-farnesol 3.40 %, (*Z*)-citral 1.87 %, (*E*)-nerolidol 1.42 % and (*E*)- β -farnesene 0.81 %. Twelve compound were obtained by hot enfleurage: *n*-undecanoic acid 31.75 %, benzyl benzoate 9.72 %, benzyl salicylate 9.70 %, (*E,E*)-2,4-dodecadialenal 8.49 %, (*E,E*)-2,4-decadialenal 6.69 %, ethyl pentadecanoate 5.94 %, farnesol 7.91 %, geranyl valerate 4.84 %, unknown1 4.01 %, octanoic acid 3.94 %, linalool 3.80 % and 193 unknown 3.22 %. The major volatile constituents of *Plumeria obtusa* white flowers, Klao Puang (L4), were *L*-linalool, geraniol 17.97 %, neral 12.5 % and benzaldehyde 5.46 % (Chitsamphandhvej 2010).

Fourteen chemical constituents were identified in the essential oil of *P. obtusa* flowers: linalool; farnesol; *trans*-farnesol; benzyl benzoate; tetradecan-1-ol; 2,3-dimethyl butane; nonadecane; heneicosane; 1 heptadecene; benzyl salicylate; 9-eicosene-(*E*); nerolidol; tricosane; and eicosane (Sulaiman et al. 2008).

Phytochemicals in Other Plant Parts

Iridoids isoplumericin, plumericin, plumieride, plumieride coumarate and plumieride coumarate glucoside were isolated from *P. obtusa* plant parts (Coppen and Cobb 1983). Pentacyclic triterpenoids

isolated from *Plumeria obtusa* leaves included betulinic acid, oleanolic acid and ursolic acid, and obtusalin elucidated as 3 β ,27-dihydroxylup-12-ene (Siddiqui et al. 1989); 2 α ,3 β -dihydroxy-24-*p*-*E*-coumaroyloxyurs-12-en-28-oic acid; 3 β -hydroxy-11-oxours-12-en-28-oic acid; 3 β ,24-dihydroxyurs-12-en-28-oic acid; 3 β -hydroxy-28-*p*-hydroxyphenoxyurs-12-en-27-oic acid; 3 β -hydroxy-27-*p*-hydroxyphenoxyurs-12-en-28-oic acid (Siddiqui et al. 1990); kaneroside, olean-drin, α -amyrin, neriucoumaric acid, isoneriucoumaric acid, alphitolic acid, oleanolic acid, methyl *p*-*E*-coumarate, scopoletin and two new triterpenes obtusin and obtusilic acid characterized as the 24-*E* and 27-*Z*-*p*-coumaric esters of the novel 3 β ,24-dihydroxyurs-12-en-28-oic acid and 3 β ,27-dihydroxyurs-12-en-30-oic acid, respectively (Siddiqui et al. 1992); obtusol and zamanic acid elucidated as 3 β ,27-dihydroxyurs-12-ene and 3 β -hydroxyurs-30-*p*-*E*-hydroxycinnamoyl-12-en-28-oic-acid (Siddiqui et al. 1999). Two new iridoids 6''-*O*-acetylplumieride *p*-*E*-coumarate and 6''-*O*-acetylplumieride *p*-*Z*-coumarate and three known iridoids as plumieride, plumieride *p*-*Z*-coumarate and plumieride *p*-*E*-coumarate were isolated from the fresh, whole spring leaves of *Plumeria obtusa* (Siddiqui et al. 1994). Begum et al. (1994) reported the isolation of 32 constituents from *P. obtusa* leaves: 12 new pentacyclic triterpenoids obtusalin, obtusin, obtusinidin, obtusilic acid, obtusidic acid, obtusilidin, obtusilidin, obtusilinic acid, obtusilic acid, obtusilinin, coumarobtusanoic acid, coumarobtusane and obtusilic acid; two new iridoids 6'-*O*-acetylplumieride *p*-*E*-coumarate and 6''-*O*-acetylplumieride *p*-*Z*-coumarate besides the known constituents; 11 pentacyclic triterpenoids betulinic acid, oleanolic acid, ursolic acid, α -amyrin, neriucoumaric acid, isoneriucoumaric acid, alphitolic acid, 3 β ,23-dihydroxyurs-12-en-28-oic acid, 27-*p*-*Z*-coumaroyloxyursolic acid, 27-*p*-*E*-coumaroyloxyursolic acid and oleanolic acid; two cardiac glycosides kaneroside and oleandrin; three iridoids plumieride, plumieride *p*-*Z*-coumarate and plumieride *p*-*E*-coumarate; a cinnamic acid derivative methyl *p*-*E*-coumarate; and a coumarin scopoletin.

Two new iridoid obtusadoids A and B along with eight known compounds plumieridin A; plumieridine; 1 α -plumieride; 15-demethylplumieride;

rel-(3R,3'S,4R,4'S)-3,3',4,4'-tetrahydro-6,6'-dimethoxy[3,3'-bi-2H-benzopyran]-4,4'-diol; gluciflavanoside B; oleanolic acid; and methyl coumarate were isolated from the methanol extract of *Plumeria obtusa* (Saleem et al. 2011).

The following chemical constituents were isolated from the fresh leaves and stem bark of *Plumeria obtusa*: four new triterpenoids dammara-12,20(22)-Z-dien-3-one; dammara-12,20(22)Z-dien-3 β -ol; olean-12-en-3 β ,27-diol; and 27-hydroxyolean-12-en-3-one and 12 known compounds, which included eight triterpenoids dammara-3 β ,20(S),25-triol; urs-12-en-3 β -hydroxy-27-Z-feruloyloxy-28-oic acid; 3 β -hydroxyolean-12-en-28-oic acid; 3 β ,27-dihydroxylupan-29-ene; 3 β -hydroxylupan-29-en-28-oic acid; 3 β -hydroxyursan-12-en-28-oic acid; 3 β -hydroxy-27-*p*-coumaroyloxy-olea-12-en-28-oic acid; and urs-2-en-3-one); an iridoid 1 α -plumieride; a cardenolide 3 α ,14 β -dihydroxy-17 β -card-20(22)-enolide; a fatty acid ester methyl *n*-octadecanoate; and a steroid 3 β -hydroxy- Δ^5 -stigmastane (Siddiqui et al. 2004).

Antiproliferative Activity

Leaf extracts of *Plumeria obtusa* displayed antiproliferative activity using the sulforhodamine B assay (Wong et al. 2011). The dichloromethane, methanol and water extract of *Plumeria obtusa* flowers were found not to be mutagenic for *Salmonella typhimurium* strains TA 98 and TA 100 without metabolic activation (Wongwattanasathien et al. 2010). However, after being treated with sodium nitrite in acid solution, the dichloromethane extract of *Plumeria obtusa* was mutagenic on both tester strains, suggesting that consumers who consume these flowers should avoid any nitrite-containing food items.

Antimicrobial Activity

The essential oil of *P. obtusa* flowers exhibited broad spectrum of inhibition of *Staphylococcus aureus* and *Bacillus cereus* (Gram-positive bacteria), *Candida albicans* and *Candida humicola* (yeast) and *Trichophyton mentagrophytes*,

T. rubrum and *Microsporum canis* (fungi). The largest inhibition zone was 1 against *C. humicola* (Sulaiman et al. 2008).

Antimutagenic Activity

The dichloromethane of *P. obtusa* flowers inhibited the mutagenicity of the reaction product of 1-aminopyrene nitrite model in the absence of metabolic activation on both *Salmonella typhimurium* strains TA 98 and TA 100, while the methanol flower extract exerted similar effect on TA 98 (Wongwattanasathien et al. 2010). The water-flower extract exhibited highest antimutagenic activity on strain TA 98. The results indicated that the flowers were safe to be consumed.

Antiulcerogenic Activity

The methanol stem bark extracts were found to be effective in healing of gastric ulcers induced by pylorus ligation and indomethacin in rats (Singh et al. 2012). The authors attributed this antiulcerogenic effect to reduction in gastric acid secretion and gastric cytoprotection and proton pump inhibition mechanism.

Algicidal Activity

Iridoids isoplumericin, plumericin, plumieride, plumieride coumarate and plumieride coumarate glucoside were isolated from *P. obtusa* plant parts (Coppen and Cobb 1983). All except for plumieride showed algicidal activity. Roots, and in particular the root bark, contained the highest concentrations of iridoids. Isoplumericin and plumericin, the compounds with the strongest algicidal activity, were rarely found in aerial parts. *Plumeria* samples were found to contain two further highly polar, but unidentified, iridoids.

Traditional Medicinal Uses

A total of 24 plant species including *Plumeria obtusa* were used by Bapedi traditional healers to

treat diabetes mellitus in South Africa (Semenya et al. 2012). *Plumeria obtusa* and *Momordica balsamina* were exclusively used to treat diabetes mellitus, and only in the Sekhukhune District.

Other Uses

Plumeria species including *P. obtusa* are suitable for landscape plantings. The flowers of all *Plumeria* species are utilized to make leis in Hawaii. The flowers are also used for making wreaths and garlands.

Comments

Plumeria species may be easily propagated from cuttings of leafless branch tips in spring. Cuttings are allowed to dry at the base before planting in well-drained soil.

world, especially Hawaii, where it flourishes abundantly.

Agroecology

It thrives in tropical to subtropical areas with warm temperature of 20–32 °C and evenly distributed annual rainfall of 1,000–2,000 mm. It is rather drought hardy but will lose its leaves under prolonged drought. In subtropical areas, it needs to be frequently watered in summer but sparingly so in winter. Frangipani does best in well-drained, fertile soils in full sun or partial shade.

Edible Plant Parts and Uses

The fruits and flowers are edible (Burkill 1966; Kunkel 1984; Facciola 1990; Hu 2005). The fruits are reported eaten in the West Indies. The flowers are eaten in sweetmeats and together with betel nut for ague. The flowers are dried and used for herbal teas. It is one of five floral components in the popular Chinese cooling herbal beverage ‘Five Flower Tea.’

Botany

Small, deciduous tree to 8 m high with pale greenish-brown, smooth, thin bark becoming rough with age. Branches swollen and leafy at the tips. Latex copious and milky white. Leaves alternate, glossy dark green on long stout petioles. Lamina simple, elliptic to narrowly elliptic, large, 15–30 cm by 6–8 cm, base acute, apex acute to acuminate, margin entire, glabrous, unicostate with 30–40 pairs of lateral veins (Plates 1, 2, 3 and 4). Inflorescences terminal, 2–3-branched cymes, 2–4-flowered with deciduous bracts. Flowers large and showy, sweetly fragrant, bracteolate, pedicellate, bisexual, actinomorphic, pentamerous, perigynous, 5–7 cm diameter. Calyx synsepalous, five obtuse lobes. Corolla sympetalous, salverform, tube cylindrical, five obovate lobes, contorted, overlapping to the left; lobes pink, red, yellow, or white, with a yellow base (Plates 1, 2, 3, 4 and 5). Stamens 5,

Origin/Distribution

Plumeria rubra is native to Mexico, Central America and Venezuela. From its native range, it has been distributed to all tropical areas of the

Plate 1 Red-flowered cultivar

Plate 2 Acute tip leaves and red-yellow flowers of a bicoloured cultivar

Plate 3 Close view of the red-yellow flowers

epipetalous alternate the lobes, inserted in corolla tube; the anthers ditheous and linear-oblong. Ovaries 2, distinct, half inferior, each ovary 1-carpelled, 1-loculed with parietal placentation, the ovules numerous in each, the style

Plate 5 Close view of white-yellow flowers

1, the stigma single and massive. Fruit follicles linear-oblong, 11–25 × 2–3 cm. Seeds oblong, plano-convex, winged, with thin fleshy endosperm.

Nutritive/Medicinal Properties

Flowers, leaves and bark of *Plumeria rubra* contain many bioactive compound with anti-cancerous, antiinflammatory and antimicrobial activities.

Phytochemicals from Flowers

P. rubra flowers were found to contain tannins, flavonoids, terpenoids, reducing sugars and alkaloids (Egwaikhide et al. 2009). Two iridoid

diastereoisomers were isolated from the flowers of *Plumeria rubra* cv. *acutifolia* (Ye et al. 2008). A new iridoid alkaloid containing a spironolactone unit, plumericidine, was isolated from the flowers of *Plumeria rubra* L. cv. *acutifolia* (Ye et al. 2009). Two anthocyanins cyanidin 3-*O*- β -(2''-glucopyranosyl-*O*- β -galactopyranoside) (75 %) and cyanidin-3-*O*- β -galactopyranoside (20 %) were isolated from ornamental reddish flowers of *Plumeria rubra* (Byamukama et al. 2011).

Norsita et al. (2006a) reported *P. rubra* pink flowers to have the following main volatile constituents: lauric acid (30.8 %), myristic acid (17.4 %), palmitic acid (9.8 %), nonadecane (8.2 %), methyl stearate (5.6 %), linalool (4.8 %), docosane (2.8 %) and tricosane (2.8 %); *P. rubra* orange flowers to have linalool (3.3 %), α -fenchyl alcohol (2.1 %), geraniol (4.1 %), (*E*)-nerolidol (14.4 %), caryophyllene oxide (3.1 %), (*E,E*)-farnesol (4.4 %), benzyl benzoate (8.6 %), myristic acid (2.9 %), 2-phenyl benzoate (3.9 %), benzyl salicylate (20.9 %), 2,6,10,14-teyramethylheptadecane (2.8 %), neryl phenylacetate (4.1 %), palmitic acid (4.4 %) and ethyl palmitate (3.1 %); reddish-orange flowers to have *n*-nonadecane (3.6 %), *n*-heneicosane (4.1 %), tricosane (3.6 %), docosane (2.7 %), pentyl benzoate (4 %), benzyl benzoate (4 %), phenylethyl benzoate (12.3 %), benzyl salicylate (4.1 %), methyl stearate (3.4 %), phenylethyl cinnamate (2 %), lauric acid (11.8 %), myristic acid (3.9 %), palmitic acid (9.3 %) and linalool (5.3 %); *P. rubra* red flowers to have *n*-nonadecane (2 %), methyl stearate (3.3 %), lauric acid (10.6 %), myristic acid (18.9 %), palmitic acid (27.2 %), linoleic acid (20.7 %), linalool (2.1 %) and terpinene-4-ol (3.7 %). Norsita et al (2006b) also reported *P. acuminata* yellowish-white flowers to have the following main volatile components: benzyl salicylate (39 %), benzyl benzoate (17.2 %), (*E*)-nerolidol (10.6 %), neryl phenylacetate (10.5 %), linalool (8.9 %), cinnamyl cinnamate (2.9 %), geraniol (2.6 %) and camphor (1.9 %) and *P. acuminata* yellow flowers to have palmitic acid (36.2 %), linoleic acid (16.8 %), lauric acid (10.4 %), myristic acid (10.3 %), pentacosane (8.1 %), tricosane (0.1 %) methyl stearate

(4.4 %). Earlier Pino et al. (1994) reported the following main volatiles from *P. rubra* var. *acutifolia* flowers: *n*-butyl oleate (13.8 %), *n*-butyl palmitate (11.5 %), methyl palmitate (9.7 %), methyl oleate (9.3 %), linalool (8.2 %), α -terpineol (7.63 %), cinnamyl alcohol (6.3 %), *n*-butyl stearate (5.3 %), benzoic acid (4.3 %), *trans*, *trans*-farnesol (3.2 %) and methyl stearate (2.8 %).

The major volatile constituents of *Plumeria rubra* white-yellow flowers (L2) were L-linalool, benzaldehyde 22.07 %, methyl salicylate 8.1 %, nerolidol 4.65 %, *trans*- β -ocimene 3.28 % and geraniol 3.08 % (Chitsamphandhvej 2010). The major volatile constituents of *Plumeria* sp. pink flowers (L1) were L-linalool 37.61 %, benzene ethanol 20.71 %, *trans*-geraniol 12.66 %, methyl benzoate 8.86 %, benzene acetonitrile 3.73 %, linalool oxide 3.37 % and nerolidol 0.95 %. The major volatile constituents of *Plumeria rubra*, Leung Anghong (L3) flowers, were *trans*- β -ocimene 48.73 %, benzene methanol 12.1 %, benzene ethanol 8.98 %, methyl salicylate 7.18 %, methyl benzoate 6.21 %, L-linalool 4.68 %, *trans*-geraniol 3.06 %, benzene acetonitrile 2.9 %, benzaldehyde 1.46 % and linalool oxide 1.03 %. The major volatile constituents of *Plumeria rubra* red flowers (L5) were isoamyl alcohol 17.96 %, *trans*-geraniol 11.86 %, benzene ethanol 8.51 %, 2-methyl-1-butanol 6.01 %, 2-methyl-2-butanal 4.47 %, benzene acetonitrile 2.34 %, methyl benzoate 1.16 % and L-linalool 1.15 %.

A total of 74 compounds were identified in the essential oil of *Plumeria rubra* forma *acutifolia* (Poir.) Woodson cv. 'Common Yellow' flowers (Omata et al. 1991). Linalool (14.1 %), phenylacetaldehyde (16.1 %), *trans*, *trans*-farnesol (11 %), β -phenylethyl alcohol (8.8 %), geraniol (5.4 %), α -terpineol (2.8 %), neral and geraniol were found to make a major contribution to the floral scent of the flower, the last two comprised 0.9 %. A total of 67 compounds were identified in the essential oil of *Plumeria rubra* 'Irma Bryan' flowers (Omata et al. 1992). β -phenylethyl alcohol (31.6 %), phenylacetaldehyde (12.1 %) and methyl cinnamate (1 %) were found to make a major contribution to the floral spicy scent of the flower, while 2-methylbutan-1-ol (10.5 %) did

not contribute to its scent. Forty-three components were identified from the flower essential oil of *Plumeria rubra* var. *acutifolia* (Li et al. 2006). The main components were fatty acid such as hexadecanoic acid, dodecanoic acid and linoleic acid; other components included terpenoids such as *trans*-nerolidol, β -linalool and *trans*-geraniol. Sixteen compounds were identified from the flower essential oil of *Plumeria rubra* cv. *acutifolia* (Han 2007). The major components in essential oil were nerolidol (20.25 %) and geranyl linalool isomer (10.1 %). Other main content components were heptacosane (7.65 %), tetradecanoic acid (6.73 %), hexadecanoic acid, 2,3-dihydroxypropyl ester (2.98 %) and 1,2-benzenedicarboxylic acid, bis(2-methylpropyl) ester (2.68 %). The main components of the essential oil of *Plumeria rubra* var. *acutifolia* extracted by supercritical carbon dioxide fluid extraction comprised 1, 6, 10-dodecatrien-3-ol; 3,7,11-trimethyl; benzoic acid; 2-hydroxy-, phenylmethyl ester; 1,2-benzenedicarboxylic acid; and bis(2-methylpropyl) ester (Xiao et al. 2011). The last components comprised 66.11 % of the total.

Seven compounds, namely, 2-methylbutan-1-ol, β -phenylethyl alcohol, nonadecane, heneicosane, benzyl salicylate, tetradecanoic acid and phenylacetaldehyde were found in the essential oil of *P. rubra* red flower variety; 19 compounds, namely, α -terpineol, geraniol, β -phenylethyl alcohol, nonadecane, heneicosane, *trans*-farnesol, benzyl benzoate, geraniol, dodecanoic acid, benzyl salicylate, phenylethyl benzoate, tetradecanoic acid, tetracosane, octadecanoic acid, tricosane, docosane, eicosane and phenylacetaldehyde in the yellow flower variety; and 14 compounds in *P. obtusa* (Sulaiman et al. 2008). The major components found in all three species were 2-hydroxybenzoic acid phenylmethyl ester. All three also shared two alkane hydrocarbons, nonadecane and heneicosane.

Phytochemicals from Plant

Albers-Schönberg and Schmid (1961) isolated isoplumericin, β -dihydroplumericin and β -dihydroplumericin along with plumericin from *Plumeria*

rubra var. *alba*. They also isolated β -dihydroplumericinic acid from the same source and also fulvoplumericin (Albers-Schönberg et al. 1962). Stearic acid was isolated from leaf and stem of *P. rubra*, and flavonoids quercetin, quercitrin found in the leaf, flower and stem of *Plumeria rubra* and *Plumeria rubra* var. *alba* (Mahran et al. 1974b).

Taraxasteryl acetate, lupeol, stigmaterol, oleanolic acid, cycloart-22-ene-3 α ,25-diol and rubrinol, a new triterpene of the ursane series, were isolated from whole plants of *P. rubra* (Akhtar et al. 1994). The structure of rubrinol was elucidated as 3 β ,30-dihydroxy-12-ursene. Two new oleanene-type triterpenes 6 α -hydroxy-3-epi-oleanolic acid and 3 α ,27-dihydroxy-olean-12-ene were isolated from *Plumeria rubra* (Akhtar and Malik 1993).

Acidic proteins with molecular masses between 12.5 and 74.5 kDa predominated in laticifers of *P. rubra* (de Freitas et al. 2010). Strong antioxidative activity of superoxide dismutase was detected in *P. rubra* latices, and to a lesser extent ascorbate peroxidase and isoforms of peroxidase were observed. In laticifer cells of *P. rubra*, four proteinases were detected, including cysteine and serine types. A protease with molecular weight of approximately 81.85 kDa was purified from the latex of *Plumeria rubra* plant and given the trivial name, plumerin-R (Chanda et al. 2011). It remained active over a broad range of temperature but had optimum activity at 55 °C and pH 7.0 when casein was used as substrate. Activation of the protease by a thiol-activating agent indicated the presence of sulphhydryl as an essential group for its activity.

Phytochemicals from Leaves

L-(+)-bornesitol was isolated from the leaves of *Plumeria acutifolia* (Nishibe et al. 1971). A new monoterpene alkaloid, (R)-4'-((S)-1-hydroxyethyl)-5,6-dihydro-5'-H-spirocyclopenta[C]pyridine-7,2'-furan)-5'-one, designated as plumerianine; the iridoid 15-demethylplumeride; and three known triterpenes, namely lupeol, uvaol and ursolic acid, were isolated from the methanol extract of *Plumeria acutifolia* leaves (Hassan et al. 2008). *P. rubra* leaves were found to contain tannins, phlobatannins,

saponins, flavonoids, steroids, terpenoids, reducing sugars, carbonyl and alkaloids (Egwaikhede et al. 2009).

Phytochemicals from Stem/Roots

The stem bark was found to contain highest content of plumierid, and *Plumeria rubra* plant contains a higher percentage of plumierid than those of *Plumeria rubra* var. *alba* (Mahran et al. 1974a). Plumerinine, a novel bicyclic lupin alkaloid, was isolated from *Plumeria rubra* stem (Kazmi et al. 1989). The following compounds were isolated from *P. rubra* bark: iridoids, fulvoplumierin, allamcin, allamandin, plumieride, α -allamcidin, 15-demethylplumieride, β -allamcidin and 13-*O-trans-p*-coumaroylplumieride; the lignan, liriodendrin, and 2,5-dimethoxy-*p*-benzoquinone (Kardono et al. 1990b). A novel flavan-3-olglycoside, plumerubroside, was isolated from a water-soluble extract of the stem bark of *Plumeria rubra*, and its structure was elucidated as (2*R*,3*S*)-3,4'-dihydroxy-7,3',5'-trimethoxyflavan-5-*O*- β -D-glucopyranoside (Kardono et al. 1990a). Two new ferulic acid derivatives, 34-hydroxy tetratriacontanyl ferulate and 34-*O*-acetyl tetratriacontanyl ferulate, were isolated, along with plumericin and isoplumericin, from *Plumeria bicolor* stem bark (Dobhal et al. 1999). A new iridoid, 15-demethylisoplumieride acid, was isolated from the bark of *Plumeria rubra* var. *acutifolia* (Barreto et al. 2007).

Four new iridoids, namely, plumeridoids A, B and C and epiplumeridoid C, were isolated from the stem bark of *Plumeria rubra* together with 24 known compounds, namely, 1-(*p*-hydroxyphenyl) propan-1-one; isoplumericin; plumericin; dihydroplumericin; allamcin; fulvoplumierin; allamandin; plumieride; *p-E*-coumaric acid; 2,6-dimethoxy-*p*-benzoquinone; scopoletin; cycloart-25-en- β ,24-diol; 2,4,6-trimethoxyaniline; arjunolic acid; ursolic acid; oleanolic acid; β -amyrin acetate; betulinic acid; lupeol and its acetate; 2,3-dihydroxypropyl octacosanoate, glucoside of β -sitosterol, and a mixture of common sterols (stigmasterol and β -sitosterol) (Kuigoua et al. 2010).

Hamburger et al. (1991) isolated six compounds from the heartwood: plumericin, isoplumericin, protoplumericine A, plumieride, 13-*O-trans-p*-

coumaroylplumieride and 4-hydroxyacetophenone 3 and several additional iridoids: 15-demethylplumieride, α -allamcidin and β -allamcidin.

Antioxidant Activity

Methanol leaf extract of *Plumeria acuminata* was found to possess antioxidant and free radical scavenging activity (Gupta et al. 2007a). The extract inhibited peroxidation of linoleic acid emulsion in a dose-dependent manner. Likewise the effect of the extract on reducing power increased in a dose-dependent manner. In DPPH radical and nitric oxide radical scavenging assays, the extract exhibited maximum activity of 60.42 and 56.38 % inhibition at the concentration of 125 μ g/ml. Further, the extract was found to scavenge the superoxide generated by PMS/NADH-NBT system. The extract also inhibited the hydroxyl radical generated by Fenton's reaction, where the IC₅₀ value of the extract was found to be 74.39 μ g/ml and for catechin the IC₅₀ value was found to be 5.27 μ g/ml.

Anticancer Activity

Six cytotoxic constituents characterized from the bark of *Plumeria rubra*, namely, three iridoids fulvoplumierin, allamcin and allamandin and 2,5-dimethoxy-*p*-benzoquinone from petroleum-ether- and CHCl₃-soluble extracts and iridoid plumericin, and the lignan liriodendrin from the water-soluble extract demonstrated general cytotoxic activity when evaluated against a panel of cell lines composed of murine lymphocytic leukemia (P-388) and a number of human cancer cell-types (breast, colon, fibrosarcoma, lung, melanoma, KB) (Kardono et al. 1990a, b). Five additional iridoids: 15-demethylplumieride, plumieride, α -allamcidin, β -allamcidin and 13-*O-trans-p*-coumaroylplumieride, were obtained as inactive constituents. Of the six compounds isolated from the heartwood, plumericin and isoplumericin exhibited cytotoxic and antibacterial activities, whereas 4-hydroxyacetophenone 3 was weakly cytotoxic (Hamburger et al. 1991). Ethanol leaf extract of *Plumeria rubra* administered orally at

the dose of 200 mg/kg body and 400 mg/kg body weight was found to increase the life span of Ehrlich ascites carcinoma-treated mice and restored the hematological parameters as compared with the untreated Ehrlich ascites carcinoma-bearing mice (Rekha and Jayakar 2011).

Plumericin from *Plumeria rubra* was listed as one of the ten most cytotoxic compounds isolated from 148 medicinal plants listed in Cameroon National Cancer Institute (NCI) database (Kuethe and Efferth 2011). The IC_{50} value for plumericin of 60 NCI cell lines were associated with the microarray-based transcriptome-wide mRNA expression. Gene products identified for plumericin activity were mainly involved in enzymatic activity and transcriptional processes or were structural constituents of ribosomes.

Antimutagenic Activity

The ethanol extract of *Plumeria rubra* leaves contains several bioactive compounds that exhibited antimutagenic activities (Guevara et al. 1996). At a dosage of 2 mg isolate/25 g mouse, unidentified compound A1 reduced the number of micronucleated polychromatic erythrocytes induced by the mutagen, mitomycin C, by 75 %; stigmast-7-enol by 80 %; lupeol carboxylic acid by 57 %; and ursolic acid by 76 %.

Antiinflammatory Activity

The methanol leaf extract also possessed potent antiinflammatory activity (Gupta et al. 2006). It exhibited significant antiinflammatory activity in both acute and chronic experimental animal models. The extract (500 mg/kg/bw) exhibited maximum antiinflammatory effect, that is, 30.51, 47.06, 34.48 and 32.50 % at the end of 3 hours using carrageenan, dextran, histamine and serotonin assays, respectively. Administration of the extract (500 mg/kg/bw) and indomethacin (10 mg/kg/bw) significantly reduced the formation of granuloma tissue induced by cotton pellet method at a rate of 45.06 and 51.57 %, respectively. The effect produced by the extract

was comparable to that of indomethacin, a prototype of a nonsteroidal antiinflammatory agent. The crude methanol extract of *Plumeria rubra* leaves was found to possess antiinflammatory (Rastogi et al. 2009). The antiinflammatory activity was dose dependent and found to be statistically significant at the concentration 100 and 200 mg/kg.

In the passive cutaneous anaphylaxis model, plumerianine isolated from the root bark of *Plumeria acutifolia* elicited a significant dose-dependent decrease in the leakage of Evans blue dye leaked at the site when compared with control (Vijayalakshmi et al. 2011). In the passive paw anaphylaxis model, plumerianine produced as significant dose-dependent decrease in paw volume induced by antiserum. Plumerianine also exhibited significant inhibition of rat paw oedema and granuloma tissue formation, including significant protection of red blood cells against the haemolytic effect of hypotonic solution, an indication of membrane-stabilizing activity. The authors postulated that anti-anaphylactic activity of plumerianine may be possibly due to inhibition of the release of various inflammatory mediators. Antiinflammatory activity of plumerianine may be related to the inhibition of the early phase and late phase of inflammatory events.

Antimicrobial Activity

Rubrinol isolated from the whole plant was found to be active against *Bacillus anthracis*, *Pseudomonas aeruginosa*, *Pseudomonas pseudomallei* and *Corynebacterium pseudodiphthericum* (Akhtar et al. 1994). Ethanol extract of the stem bark exhibited in vitro antimicrobial activity against Gram-positive bacteria (*Bacillus subtilis*, *Enterococcus faecalis*, *Staphylococcus aureus*), Gram-negative bacteria (*Escherichia coli*, *Klebsiella pneumoniae*, *Pseudomonas aeruginosa*, *Salmonella typhimurium*) and fungi (*Aspergillus niger* and *Candida albicans*) (Rasool et al. 2008). The ethanol extract showed the strong in-vitro antimicrobial activity against *E. faecalis*, *B. subtilis*, *S. aureus*, *P. aeruginosa*, *S. typhimurium*, *A. niger* and *C. albicans*.

The crude methanol leaf extract of *P. acuminata* inhibited the growth of both Gram-positive bacteria (*Bacillus subtilis*, *Staphylococcus aureus* and *Micrococcus luteus*) and Gram-negative bacteria (*Escherichia coli*, *Pseudomonas aeruginosa* and *Salmonella typhimurium*) (Gupta et al. 2008). Gram-positive bacteria tested appeared to be more susceptible to the extract than the Gram-negative bacteria. The extracts also showed significant antifungal activity against *Aspergillus niger* and *Candida albicans*. All tested microorganisms showed dose-dependent susceptibility towards the methanol extracts. Ethanol and chloroform leaf extracts of *P. rubra* exhibited partial antibacterial activity in vitro against *Staphylococcus epidermidis* at 750 and 1,000 µg/ml but at 1,500 µg/ml was completely inhibitory to *S. epidermidis* and *Escherichia coli* (Baghel et al. 2010). The ethyl acetate and aqueous leaf extract was partially inhibitory to *S. epidermidis* at 1,000 µg/ml but at 1,500 µg/ml was completely inhibitory to *S. epidermidis* and *Escherichia coli*. The standard drug ciprofloxacin is showing complete antibacterial activity against *S. epidermidis* and *Escherichia coli* at 500 and 750 µg/ml, respectively.

The methanol extract of *P. rubra* flowers inhibited significantly in-vitro growth of *Corynebacterium pyogenes*, *Staphylococcus aureus*, *Streptococcus faecalis*, *Bacillus stearothermophilus*, *Staphylococcus epidermidis*, *Bacillus cereus*, *Bacillus polymyxa*, *Klebsiella pneumoniae*, *Pseudomonas aeruginosa*, *Bacillus anthracis*, *Bacillus subtilis*, *Escherichia coli*, *Pseudomonas fluorescens* and *Clostridium sporogenes* (Egwaikhede et al. 2009). The methanol leaf extract was also inhibitory but comparatively less to all the bacteria tested and was not inhibitory to *Corynebacterium pyogenes* and *Klebsiella pneumoniae*.

The essential oil of *P. rubra* red flower variety inhibited growth of *Bacillus cereus*, *Candida albicans*, *Candida humicola* and *Trichophyton rubrum*, while the essential oil from the yellow flower variety inhibited growth of *Bacillus cereus* and *Candida humicola* (Sulaiman et al. 2008). *Plumeria rubra* was one of four Latin American plant extracts that exhibited inhibitory activity against the subcutaneous fungus *Fonsecaea pedrosoi* with MIC of 12.5 µg/ml (Gaitán et al. 2011)

Antiviral Activity

Plumeria rubra yielded the iridoid, fulvoplumerin—an active, inhibitory compound with an IC₅₀ 45 µg/ml against the human immunodeficiency virus type 1 reverse transcriptase (HIV-1 RT) (Tan et al. 1991).

Larvicidal Activity

Silver nanoparticles (AgNPs) synthesized using *Plumeria rubra* plant latex were found to be toxic to second and fourth larval instars of *Aedes aegypti* and *Anopheles stephensi* (Patil et al. 2012). AgNPs were more toxic to the larval stages than the crude latex extract. Toxicity studies carried out against nontarget fish species *Poecilia reticulata*; the most common organism in the habitats of *A. aegypti* and *A. stephensi* showed no toxicity at LC₅₀ and LC₉₀ doses of the AgNPs.

Hypoglycemic Activity

P. rubra was reported as one of several Mexican medicinal plants used in folkloric medicine to control diabetes mellitus (Hernandez-Galicia et al. 2002). Treatment of alloxan-induced hyperglycaemic rats with the flavone glycoside from *P. rubra* significantly reduced the level of serum triglycerides but did not alter blood glucose and serum total cholesterol (Merina et al. 2010). Administration of the glycoside significantly reduced the elevated levels of blood urea and creatinine and the activities of aspartate aminotransferase (SGOT) and alanine aminotransferase (SGPT) when compared with the hyperglycaemic control animals. Antioxidant activity of the flavone glycoside was also confirmed through in-vitro studies wherein the rate of malondialdehyde formation was markedly inhibited. The authors concluded that the beneficial effect of the flavone glycoside treatment on triglycerides observed assumes greater significance as a useful drug to decrease hyperlipidemic risks in diabetes.

Antipyretic and Antinociceptive Activity

Gupta et al. (2007b) showed that a single oral administration of different doses (100, 250 and 500 mg/kg) of the methanol leaf extract of *P. acuminata* significantly reduced brewer's yeast-induced hyperthermia in rats. The extract also elicited pronounced inhibitory effect on acetic acid-induced writhing, hot plate, tail-flick and tail immersion responses in mice in the antinociceptive tests.

Intraperitoneal administration of boiled milk at a dose 0.5 ml/kg body weight in albino rabbit led to pyrexia; this pyrexia was reverted by intraperitoneal administration of ethanol leaf extract of *P. rubra* at a dose 200 mg/kg body weight (Misra et al. 2012). The extract significantly reduces the elevated body temperature of rabbit which was compared with aspirin (standard drug) and solvent used.

Anxiolytic Activity

Subchronic oral administration of *Plumeria rubra* flower ethanol extract at 100 mg/kg p.o. to male Swiss mice increased the time spent in the open arms of the elevated plus-maze test (Chatterjee et al. 2013). The extract was further fractionated into hexane, chloroform, butane soluble and *n*-butane-insoluble fractions, out of which the butanol-insoluble fraction (BIF) showed significant anxiolytic activity comparable to standard anxiolytic drug, diazepam. Both the flower ethanol extract and BIF did not show any significant alterations in the horizontal activity, total distance and stereotypy count in the activity monitor. No motor incoordination side effects were observed after the extract and BIF pretreatment in the rotarod test in mice.

Antifertility Activity

Studies in female Sprague–Dawley rats showed that the aqueous (2 g/kg), ethanol (0.75 g, 1.3 and 1.5 kg/kg), methanol and dichloromethane

(1.3 g and 1.5 g/kg) extracts of stem bark of *Plumeria rubra* exhibited antifertility activity (Gunawardana et al. 1998). The extracts were embryotoxic causing foetal death and subsequent resorption. Toxic symptoms observed in these experiments included reduced food intake, loss of body weight, and diarrhoea. Two deaths were recorded in the dichloromethane-treated group. The weight loss observed with some extracts, which showed significant antifertility activity, varied from slight to moderate to large.

The aqueous, alcohol, ethyl acetate and chloroform extract of *P. rubra* pods exhibited abortifacient activity (8–10 %) when administered to pregnant rats from day 11 to 15 of pregnancy (Dabhadkar and Zade 2012). The extracts significantly reduced the number of live foetuses, and the resorption index and post-implantation losses increased significantly. The percent of abortion was found to be highest (100 %) with 200 mg/kg dose of alcohol extract of *P. rubra* pods. In another paper, they reported that the ethanol extracts of *P. rubra* pods exhibited abortifacient activity (13.46–100 %) (Dabhadkar et al. 2012). The extract significantly reduced the number of live foetuses, whereas the resorption index and post-implantation losses increased significantly. The rate of abortion was found to be highest (100 %) at 200 mg/kg dose of alcoholic extract of *P. rubra* pods. In ovariectomized immature young rats, the extract showed significant estrogenic effect (vaginal opening, vaginal cornification and increased uterine weight) at the dose 200 mg/kg body weight. The phytochemical screening revealed the presence of alkaloids, flavonoids, simple phenolics, steroids, tannins and saponins in the extract.

Anthelmintic Activity

The crude methanol extract of *Plumeria rubra* leaves was found to possess anthelmintic activity (Rastogi et al. 2009). The anthelmintic effect of at 25 mg/ml concentration was comparable to the reference standard piperazine citrate.

Molluscicidal Activity

Of the six compounds isolated from the heartwood, plumericin and isoplumericin exhibited molluscicidal activity (Hamburger et al. 1991).

Toxic Immunoreactive Activity

Radford et al. (1986) found significant amounts of immunoreactive cardiac glycoside in *Plumeria rubra*. Awareness of the existence of such compound in *Plumeria* and their dangers allows them to be avoided and poisoning prevented.

Traditional Medicinal Uses

In traditional medicinal system, different parts of the plant have been mentioned to be useful in a variety of diseases. In India, the plant material is widely used as a purgative, remedy for diarrhoea and cure for itch. The milky juice is employed for the treatment of inflammation and rheumatism. The bark has been reported to be useful in hard tumours, diarrhoea, fever and gonorrhoea. The flowers are eaten with betel nut to cure ague.

In Mexico, the natives used it for skin complaints, for intermittent fevers and for dispersing dropsies by purging when applied to the stomach. In the West Indies, the bark is diuretic and the latex is used for purging. In the Philippines, the bark is used as a purgative, emmenagogue and febrifuge; the latex has the same effects. In Java and Madura, the bark is given for gonorrhoea, dropsy and dysuria due to venereal disease. The milky latex is used as a counterirritant for toothache and for sores. A decoction of the leaves is applied as lotion for cracks and eruptions on the sole of the feet and the paste of the leaves for poulticing swellings. In Thailand, a flower infusion is used as cosmetic applied after bathing but is slightly rubefacient. In Myanmar, the shoot, bark and flowers are employed for leprosy, for pruritis and for healing boils, carbuncles, and ascites. They are analgesic and employed as febrifuge for persistent fever. The bark and leaves are used for rheumatism, abdominal tumours and

inflammation. The flower and shoots are used also for Malaria. In Mexico, decoction of flowers is used in diabetes.

Flowers of *Plumeria rubra*, *Chrysanthemum morifolium*, *Lonicera japonica*, *Bombax morifolium*, and *Sophora japonica* are the five primary constituents of the popular cooling herbal beverage 'Five Flower Tea' (Hu 2005; Kong et al. 2006). This Five Flower Tea is one of the top five remedies for 'Hot Qi' (Kong et al. 2006). 'Hot Qi' is often used by Chinese parents to describe listless symptoms in their children in Hong Kong. Eye discharge (37.2 %), sore throat (33.9 %), halitosis (32.8 %), constipation (31.0 %), and irritability (21.2 %) were the top five symptoms of 'Hot Qi' in children in Hong Kong.

P. rubra is one of several plants reported to be used for permanent sterilization for birth control in different parts of Assam, India (Tiwari et al. 1982). The Irula tribe of the Chittoor district of Andhra Pradesh use the flowers to treat itch (Vedavathy et al. 1997).

Other Uses

P. rubra has become a popular ornamental landscape tree in many tropical and subtropical countries. Flowers are popularly used in garlands or leis in Hawaii and also for wreaths elsewhere. In 2005 over 14 million blooms were sold for lei in Hawaii (Criley 2009). Collectors have descended upon Hawaii to find different colour forms, fragrances and flower shapes, and the fever to own a new plant has brought prices as high as \$75 per cutting for rare and unusual forms. The blooms are often used for decorating bath in aroma therapy. *P. rubra* is Laos national flower.

Comments

It can be differentiated from *Plumeria obtusa* using salient leaf characteristics; in *Plumeria rubra*, the leaf blade is acute or acuminate at apex, matte adaxially and glaucous. In *Plumeria obtusa*, the leaf blade is rounded at apex, shiny adaxially and dark green.

Telosma cordata

Scientific Name

Telosma cordata (Burm.f.) Merrill

Synonyms

Asclepias cordata Burm.f., *Asclepias pallida* Roxb., *Cynanchum odoratissimum* Loureiro, *Oxystelma ovatum* P.T. Li & S.Z. Huang, *Pergularia minor* Andrews, *Pergularia odoratissima* (Loureiro) Roxb. ex Smith, *Telosma minor* (Andrews) W.G. Craib, *Telosma odoratissima* (Loureiro) Coville

Family

Asclepiadaceae

Common/English Names

Chinese Violet, Cowslip, East Coast Creeper, Fragrant Telosma, Night Fragrant Flower, Pakalana Vine, Primrose Creeper, Tonkin Creeper, Tonkin Jasmine, Tonkin Telosma

Vernacular Names

Chinese: Ye-Lai-Xiang, Yeh-Lai-Hsiang, Ye-Xiang-Hua, Yeh-Hsiang-Hua

French: Parfum Nocturne, Pergulaire

Hawaiian: Miulana Ke'oke'o, Pakalana

India: Surkillā (Hindi), Cambangikkodi (Tamil), Alapaala, Errumalle-tige, Konda Male-tige, Seethamanoharamu (Telugu), Kusiari (Uttar Pradesh), Kanjalate, Seetamanoharam

Malaysia: Bunga Siam, Bunga Tonkin, Melati Tonkin

Spanish: Fragancia Nocturna

Thai: Salit

Vietnamese: Thiên Lý, Hoa Thiên Lý

Origin/Distribution

The plant is a native of India, Burma, Indochina and South China. It is widely cultivated in Southeast Asia especially in Thailand, Vietnam and Malaysia. It was introduced and cultivated in Java from the seventeenth century.

Agroecology

In its native range, the plant is found in secondary forest, bushland and open woods in low elevation in the subtropics and tropics. It is also cultivated in home gardens. It thrives in full sun in well-drained, fertile sandy-loam soil with optimum pH 6.1–7.5. It is tolerant to drought and poor soil but sensitive to flooding and cold.

Edible Plant Parts and Uses

Opened and unopened flowers in umbels and young leaves are eaten as vegetables in China, Thailand, Vietnam, Kampuchea and Laos, cooked in soups or stir-fries with eggs and with meat (Burkill 1966; Uphof 1968; Facciola 1990; Hu 2005; Tanaka and Nguyen 2007; Yang et al. 2008). Tuberous roots are also eaten as sweetmeat by the Chinese in Java. Flowers yield an oil which is used in cooking.

Botany

Small, perennial, climber growing to 10 m long with much-branched, yellowish green stem, pubescent when young becoming pale grey and glabrescent (Plate 1). Leaves borne on 1.5–5 cm long petioles. Leaf lamina ovate, 6–11 cm long, base deeply cordate with narrow sinus, apex acuminate; basal veins 3, lateral veins to six pairs, glabrous or puberulous on the nerves (Plates 1, 2 and 3). Flowers in 15–30-flowered, umbellate cymes, puberulent, fragrant especially at night (Plates 4 and 5). Bract linear, caducous. Sepals oblong-lanceolate, puberulent on the outside. Corolla greenish-yellow to pale yellow, salver-shaped, tube 6–10×4–6 mm, puberulent outside, with ciliate, oblong-linear lobes, twisted in bud (Plates 1 and 3). Corona in one series with slightly fleshy lobes, basal part ovate, apex acuminate, often notched to deeply lobed, internal

appendage often longer than lobe proper. Pistil with two carpels with numerous ovules on sub-marginal placenta. Filaments united, anthers with two locules each with one oblong or reniform pollinia. Stigma large, capitate. Follicles lanceolate 6–12×2–3.5 cm, glabrous, somewhat

Plate 4 Unopened flower buds

Plate 5 Harvested flowers and buds on sale in a local market

obtusely 4-angled. Seeds broadly ovate, 1×1 cm, flat, apex truncate, margin membranous bearing 3–4 cm long silky coma.

Nutritive/Medicinal Properties

The flower bud was reported to have the following nutrient compositions: 11 g dry matter, 1.18 g fiber, 2.62 g sugar, 3.13 g protein, 0.74 mg vitamin C, 52 mg β -carotene, 19 mg Ca and 0.92 mg Fe (Kuo 2002). Flavonoid content (mg/100 g FW) of the flower bud amounted to 12.8 % dry matter made up of the following flavonoids (mg/100 g FW): quercetin 0.2 mg, kaempferol 8.7 mg and total flavonoids 8.9 mg (Yang et al. 2008). A total of 43 compounds were identified from the essential oil of *Telosma cordata* flowers (Arai et al. 1993). Geraniol, β -ionone, dihydro- β -ionone, dihydro- β -ionol and *cis*-theaspirane and *trans*-theaspirane were found to contribute largely to the characteristic scent of the flower.

Comparison of mean vitamin C concentrations resulting from different cooking methods in leaves and tender tips and flower vegetables showed conventional stir-fried pagwanpa, pagwanban and cowslip creeper (*Telosma cordata*) to be excellent sources of vitamin C (64.4–70.8 mg/100 g) (Somsu et al. 2008).

The methanol extract from the leaves of *Telosma cordata* showed in-vitro cytotoxic activity against Hep-G2 (hepatonema carcinoma),

Fl (fibril sarcoma of uterus) and RD (rhabdosarcoma) with the ED₅₀ values of 39.0, 12.6, and 5.6 %, respectively (Le et al. 2005). Fractionation of the extracts gave compounds belonging to different classes. Four compounds lutein, 1-dotriacontanol, 24*E*-stigmasta-5,22-dien-3 β -ol and daucosterol were isolated from the n-hexane extracts.

Traditional Medicinal Uses

Fragrant *Telosma* oil is used medicinally in traditional medicine to treat conjunctivitis. The plant is used as antipyretic, an antidote to poison, tranquilizer and fatigue reducer. It is also used to relieve backbone aches and to decrease hematuria (Tanaka and Nguyen 2007).

The Kol tribes of Vindhyan region of Uttar Pradesh apply latex of the fruit and fruit paste of *Telosma pallida* externally on the localized white patches during the initial stage of leucoderma disease (Singh and Narain 2010).

Other Uses

It is also planted as an ornamental creeper. The flowers are very fragrant and yield a perfumed oil. The plant is readily propagated from stem cuttings or seeds.

Comments

Some botanists are of the view that *Telosma cordata* is possibly a cultigen of *T. pallida* selected for fragrant flowers.

Origin/Distribution

The origin of *Agave sisalana* is in Central America, probably in southern Mexico based on the strength of traditional local usage (Gentry 1982). In the nineteenth century, sisal cultivation spread to Florida, the Caribbean islands, Brazil, parts of Africa notably Tanzania, Kenya and Madagascar, Asia, the Pacific Islands and Australia where it has become naturalized. *Agave* has become an invasive weed species in some countries like Australia where it develops dense infestations which can prevent the regeneration of trees and exclude understorey species in native bushland.

Agroecology

Sisal is a robust, hardy tropical species found growing from near sea level to a 1,800 m altitude as in tropical Africa. In its native and naturalized range, it can be found in bushland, roadsides, savanna and along drainage lines. It thrives in full sun, in areas with a maximum temperature of 27–32 °C and minimum temperatures of 16 °C or higher and daily fluctuations not exceeding 7–10 °C. It grows best in regions with an average annual rainfall of 1,000–1,250 mm but is often grown with less rain as in semiarid areas. Excessive rainfall is detrimental to the plant. Under dry conditions or at low average temperatures, it forms fewer leaves per year and has a longer life cycle. Sisal prefers sandy-loam soils but can be grown on a range of soils, provided they are rich in bases, especially calcium, and well drained. Sisal is intolerant of waterlogging. Optimum pH is between 5.5 and 7.5, though sisal has been grown on soils with pH 4–5.

Edible Plant Parts and Uses

Five major parts of the *Agave* are edible: the flowers, the leaves, the stalks or basal rosettes, the sap (called aguamiel—honey water) (Davidson 2006; Deane 2012), and the roots (Deane 2012).

Each *Agave* plant will produce several pounds of edible flowers during the summer. The flower stalks before flower opening can be harvested, roasted and eaten; they are sweet, like molasses. During inflorescence development, the base of the young flower stalk is rich in sap and yields a syrup (also called *Agave nectar*) when tapped, which is used as an alternative to sugar in cooking, and is promoted as a healthy alternative or fermented into alcoholic beverage, pulque or mescal. The leaves may be collected in winter and spring—when the plants are rich in sap—boiled and eaten. In Java, the heart of new shoot is eaten (Tanaka 1976). The root is caustic, but once cooked for a couple of days it is sweet and can be eaten.

Botany

A robust, monocarpic herbaceous perennial with a short thick stem 120 cm by 20 cm, with a basal rosette of numerous (50–>150) leaves, 1.5–2 m high (Plates 1 and 2). Leaves glaucous when young, margin minutely spiny, later dark blue-green, ensiform, linear-lanceolate, straight 100–150 cm long by 10–15 cm wide, succulent, adaxially concave, abaxially convex, margin not spiny, apex straight and tipped with a red-brown spine 2–3 cm. Inflorescence a panicle on a long peduncle, 2–8 m tall, branching at the upper half, branches widely spreading, 30–100 cm by 2 cm, apically 5–6 times branched trichotomously, bearing about 40 flowers per branch and bearing numerous bulbils on the inflorescence branches after anthesis (Plate 2). Flowers strongly odorous,

Plate 1 Immature sisal plant

Plate 2 Mature, flowering sisal plants

erect, protandrous; pedicel short; perianth tubular, 6-lobed, 5–6 cm long, pale yellowish green, tube 1–2 cm long, lobes obovate-oblancheolate, on inner side of the top with a tuft of hairs; stamens 6, attached above the middle of the perianth tube, 6–8 cm long; ovary inferior, 3-loculed, style 6–7 cm long, stigma 3-lobed. Fruit (rarely produced) an ellipsoid capsule, green becoming black when matured containing about 150 seeds. Seeds rounded-deltoid, thin, flat and black.

Nutritive/Medicinal Properties

Agave sisalana juice was found to be acidic (pH=5.42) and to contain abundant water 93.73 %, 11.56 % crude protein, 1.11 % total soluble sugar, 1.48 % ash and 8.7 % inulin content (stored juice), while fresh juice had 20.87 % inulin (Sharma and Varshney 2012). Wilson (1971) reported that sisal fibre contained 78 % cellulose, 8 % lignin, 10 % hemicelluloses, 2 %

waxes and about 1 % ash by weight. Rowell (1992) reported sisal to contain 43–56 % cellulose, 7–9 % lignin, 21–24 % pentosan and 0.6–1.1 % ash. Joseph et al. (1996) reported sisal to contain 85–88 % cellulose. *Agave sisalana* was found to contain 77.3–84.4 % cellulose and 6.9–10.3 % hemicelluloses, lignin 7.4–11.4 (Martin et al. 2009). Sisal leaf was reported to contain about 4 % by weight of extractable hard fibre, with the remains from the leaf still possessing up to 20 % by weight of extractable pulp and short fibres, the remainder being water and soluble sugars and the stem (bole) and the pole contained abundant solid pulp and liquid juice with a high concentration of soluble sugars (Bisanda and Enock 2003). Sisal pulp was found to have a crude protein of 7.3 %, crude fibre of 15.2 % and NFE (nitrogen free extract) 59.6 % (Gebremariam and Machin 2008). Sisal plant was reported to contain three types of fibres: structural (mechanical) occurring in the periphery of the leaf (most useful fibre); ribbon, longest fibres, occurring in association with the conducting tissues in middle of the leaf; and xylem fibres with thin-walled cells in the conducting vascular bundles (Bisanda and Ansell 1992; Li et al. 2000).

Agave sisalana and kenaf (*Hibiscus cannabinus*) were found to contain highly gamma-acylated lignins with acetate groups (del Río et al. 2008). The structures of all these highly acylated lignins were characterized by a very high syringyl/guaiacyl ratio, a large predominance of β -O-4' linkages (up to 94 % of all linkages), and a strikingly low proportion of traditional beta-beta' linkages. The occurrence of beta-beta' homocoupling and cross-coupling products of sinapyl acetate in the lignins from sisal and kenaf indicated sinapyl alcohol to be acetylated at the monomer stage and that, therefore, sinapyl acetate should be considered as a real monolignol involved in the lignification reactions. The acetylated heteroxylan O-acetyl-(4-O-methylglucurono)xylan with a molecular weight (Mw) of 18 kDa was isolated from *Agave sisalana* (Marques et al. 2010). The heteroxylan backbone was composed of (1 \rightarrow 4)-linked β -D-xylopyranosyl units (Xylp) partially branched with terminal (1 \rightarrow 2)-linked 4-O-methyl- α -D-glucuronosyl

(MeGlc_pA, 9 mol%) and a small proportion of α-D-glucuronosyl (Glc_pA, <1 mol%) residues. Roughly 61 mol% of Xyl_p residues were acetylated.

Agave sisalana was also reported to contain sapogenins and saponins. The distribution of the steroid sapogenin constituents of *Agave sisalana* at various phases of growth was studied by Dawidar and Fayeze (1961). It was suggested that in the bulbils, gitogenin (as first generation in sapogenin biogenesis) afforded tigogenin (as second generation) which was transformed during the course of the long life of the plant to hecogenin and neotigogenin (as third generation). At the end of the life cycle, neotigogenin and hecogenin of the old leaves were transformed by a reverse mechanism to tigogenin in the flowering top and then to gitogenin. They found that hecogenin was most abundant (0.235 %) in the leaves of the old plant. The major sapogenins (hecogenin, 9(11)-dehydrohecogenin and tigogenin) occurring in the *Agave* species including *A. sisalana* were analyzed by reversed-phase high-performance liquid chromatography (Higgins 1976). Sarsasapogenin, 9(11)-dehydrotigogenin and diosgenin were also analyzed by this rapid and accurate method. Rockogenin was found to be formed from hecogenin during processing of *A. sisalana* leaves (Blunden et al. 1977); hecogenin 3β-hydroxy-(25R)-5α-spirostan-12-one and tigogenin (25R)-5α-spirostan-3β-ol were isolated from *A. sisalana* leaf and leaf juice, crude saponin concentrates known as 'coffee grounds' (Cripps and Blunden 1978). In East African samples, the tigogenin proportion of the total sapogenin content is usually about 10 %. Leaves of Tanzanian, Kenyan and Angolan *A. sisalana* plants were found to have 0.34, 0.47 and 1.16 % hecogenin and 0.2, 0.2 and 0.1 % tigogenin, respectively (Sitton et al. 1982).

Barbourgenin a steroidal sapogenin, rockogenin and chlorogenin were isolated from coffee grounds produced from the acid hydrolyzed juice of the leaves of *A. sisalana* (Blunden et al. 1986). Three steroidal saponins, dongnosides C–E, were isolated from the methanol extracts of the fermented

residues of leaf juices of *Agave sisalana* and their structures elucidated as tigogenin-3-*O*-β-D-xylopyranosyl(1 → 2)[β-D-glucopyranosyl(1 → 3)]β-D-glucopyranosyl(1 → 4)β-D-galactopyranoside, tigogenin-3-*O*-β-D-xylopyranosyl(1 → 3)β-D-xylopyranosyl(1 → 2)[β-D-glucopyranosyl(1 → 3)]β-D-glucopyranosyl(1 → 4)β-D-galactopyranoside and tigogenin-3-*O*-α-L-rhamnopyranosyl(1 → 4)β-D-xylopyranosyl(1 → 2)[β-D-glucopyranosyl(1 → 3)]β-D-glucopyranosyl(1 → 4)β-D-galactopyranoside, respectively (Ding et al. 1989).

Two major steroidal saponins, named dongnosides B and A, were isolated from *A. sisalana* leaf juice, and their structures characterized, respectively, as tigogenin 3-*O*-α-L-rhamnopyranosyl-(1 → 4)-β-D-glucopyranosyl-(1 → 2)-[β-D-glucopyranosyl-(1 → 3)]-β-D-glucopyranosyl-(1 → 4)-β-D-galactopyranoside and 3-*O*-α-L-rhamnopyranosyl-(1 → 4)-β-D-glucopyranosyl-(1 → 2)-[β-D-xylopyranosyl-(1 → 3)]-β-D-glucopyranosyl-(1 → 3)]-β-D-glucopyranosyl-(1 → 4)-β-D-galactopyranoside (Ding et al. 1993). Two furostanol saponins were isolated from *Agave sisalana* leaves, and their structures established as (25S)-26-(β-D-glucopyranosyl)-22xi-hydroxyfurost-12-one-3β-yl-*O*-α-L-rhamnopyranosyl-(1 → 4)-β-D-glucopyranosyl-(1 → 3)-*O*-[*O*-β-D-glucopyranosyl-(1 → 2)]-*O*-β-D-glucopyranosyl-(1 → 4)-β-D-galactopyranoside and (25S)-26-(β-D-glucopyranosyl)-22xi-hydroxyfurost-5-en-12-one-3β-yl-*O*-α-L-rhamno-pyranosyl-(1 → 4)-β-D-glucopyranosyl-(1 → 3)-*O*-[*O*-β-D-glucopyranosyl-(1 → 2)]-*O*-β-D-glucopyranosyl-(1 → 4)-β-D-galactopyranoside (Zou et al. 2006). Three flavonoids 5,7-dihydroxyflavanone (1), kaempferol 3-rutinoside-4'-glucoside (9) and kaempferol 3-(2G-rhamnosylrutinoside) (10) and seven homoisoflavonoids 7-*O*-methyleucomol (2) [9], 3'-deoxysappanone (3), (±)-3,9-dihydroeucomin (4), dihydro-bonducellin (5), 7-hydroxy-3-(4-hydroxybenzyl)chromane (6) 5,7-dihydroxy-3-(4'-hydroxybenzyl)-4-chromanone (7), and 5,7-dihydroxy-3-(3'-hydroxy-4'-methoxybenzyl)-4-chromanone (8) were isolated from methanol extraction of *Agave sisalana* leaves (Chen et al. 2009).

A furostanol saponin, sisalasaponin C (1), and a spirostanol saponin, sisalasaponin D (2), were isolated from the fresh leaves of *Agave sisalana*, along with three other known steroidal saponins and two stilbenes (Yu et al. 2011). Their structures were identified as (3 β ,5 α ,6 α ,22 α ,25 R)-3,26-bis[(β -D-glucopyranosyl)oxy]-22-hydroxy furostan-6-yl β -D-glucopyranoside (1); (3 β ,5 α ,25 R)-12-oxospirostan-3-yl 6-deoxy- α -L-mannopyranosyl-(1 \rightarrow 4)- β -D-glucopyranosyl-(1 \rightarrow 3)-[β -D-xylopyranosyl-(1 \rightarrow 3)- β -D-glucopyranosyl-(1 \rightarrow 2)]- β -D-glucopyranosyl-(1 \rightarrow 4)- β -D-galactopyranoside (2); (3 β ,5 α ,6 α ,22 α ,25 R)-22-methoxyfurostane-3,6,26-triyl tris- β -D-glucopyranoside; cantalasaponin-1; polianthoside D; (*E*)-2,3,4',5-tetrahydroxystilbene 2-*O*- β -D-glucopyranoside; and (*Z*)-2,3,4',5-tetrahydroxystilbene 2-*O*- β -D-glucopyranoside.

The most predominant compounds identified in the lipophilic extract of *A. sisalana* fibres were fatty acids (30 % of total lipids) including α - and ω -hydroxy fatty acids, fatty alcohols (20 %), free sterols (11 %), alkanes (11 %) and a series of ferulic acid esters of long-chain alcohols and ω -hydroxy fatty acids (10 %) (Gutiérrez et al. 2008). Additionally, steroid hydrocarbons and ketones, monoglycerides, aldehydes, waxes and sterol glycosides were also found together with minor amounts of diglycerides and sterol esters. D-mannitol was isolated from an ethanol extract from the liquid residue of *Agave sisalana* (Branco et al. 2010). D-mannitol was isolated from an ethanol extract from the liquid residue of *Agave sisalana* leaf waste (Branco et al. 2010). *Agave sisalana* juice waste aqueous extract was found to contain saponins, glycosides, phlobatannins, terpenoids, tannins, flavonoids and cardiac glycosides (Ade-Ajayi et al. 2011).

Anticancer Activity

Steroidal sapogenins and saponins—tigogenin (1), neotigogenin (2), hecogenin (3), neohecogenin (4), rockogenin (5), cantalasaponin-1 (6), hecogenin 3-*O*- β -D-glucopyranosyl-(1 \rightarrow 2)-[β -D-xylopyranosyl-(1 \rightarrow 3)]- β -D-glucopyranosyl-(1 \rightarrow 4)- β -D-

galactopyranoside (7), hecogenin 3-*O*- α -L-rhamnopyranosyl-(1 \rightarrow 3)- β -D-xylopyranosyl-(1 \rightarrow 2)-[β -D-xylopyranosyl-(1 \rightarrow 3)- β -D-glucopyranosyl-(1 \rightarrow 3)]- β -D-glucopyranosyl-(1 \rightarrow 4)- β -D-galactopyranoside (8), a furostanol saponin, polianthosides E (9) and neotigogenin 3-*O*- α -L-rhamnopyranosyl-(1 \rightarrow 4)- β -D-lucopyranosyl-(1 \rightarrow 2)-[β -D-xylopyranosyl-(1 \rightarrow 3)- β -D-glucopyranosyl-(1 \rightarrow 3)]- β -D-glucopyranosyl-(1 \rightarrow 4)- β -D-galactopyranoside (10)—were isolated from *A. sisalana* (Chen et al. 2011). Compounds 7–10 showed significant cytotoxicity against MCF-7, NCI-H460 and SF-268 cancer cells compared to the positive control actinomycin D. Compound 10 was the most cytotoxic with IC₅₀ values of 1.2, 3.8 and 1.5 μ M against MCF-7, NCI-H460 and SF-268 cancer cells, respectively.

Immunomodulatory Activity

The following flavonoids from *A. sisalana* leaves, (+/-)-3,9-dihydroeucumin (4), dihydrobonducellin (5), and 5,7-dihydroxy-3-(4'-hydroxybenzyl)-4-chromanone (7), showed inhibitory effects on human peripheral blood mononuclear cell (PBMC) proliferation activated by PHA with IC₅₀ values 19.4, 73.8, and 58.8 μ M, respectively (Chen et al. 2009). All three compounds significantly inhibited the production of interleukin IL-2 and interferon IFN-gamma in activated PBMC in a concentration-dependent manner.

Gastroprotective Activity

Studies showed that pretreatment of mice with hecogenin, a steroid saponin isolated from *Agave sisalana*, before ethanol or indomethacin challenge, exhibited significant gastroprotective effect (Santos Cerqueira et al. 2012). The hecogenin pretreatment normalized GSH levels and significantly reduced lipid peroxidation and nitrite levels in the stomach, as evaluated by the ethanol-induced gastric lesion model. It was further found that the gastroprotective effect appeared to be mediated by K⁺(ATP) channels opening and the COX-2/PG pathway.

Anthelmintic Activity

In-vitro tests showed sisal juice caused more than 95 % reduction in larval counts of the genus *Haemonchus* spp. at concentrations between 86.5 and 146.3 mg/ml (Domingues et al. 2010). In-vivo sisal juice also reduced larvae of the fourth (L4) and fifth (L5) stages of *Haemonchus*, *Oesophagostomum* and *Trichostrongylus* in goats. *A. sisalana* shredded leaf extract showed in-vitro dose-dependent activity against sheep and goat gastrointestinal nematodes (Silveira et al. 2012). The LC₅₀ and LC₉₅ in the egg hatch test were 6.90 and 24.79 mg/ml, in the larval development test were 0.041 and 0.067 mg/ml and in the larval feeding inhibition test were 0.053 and 0.24 mg/ml. The development and feeding inhibition on L(1) larva were both 100 % at a dose of 0.12 mg/ml. In the adult motility test, there was 100 % inhibition at 75 mg/ml after 24 hours of exposure. The extract of *A. sisalana* therefore demonstrated significant action on L(1) at 0.12 mg/ml. Treatment of goats naturally infested by gastrointestinal nematodes with aqueous extract from sisal waste and levamisole phosphate caused a significant reduction in the number of eggs and infective larvae (L(3)) (Botura et al. 2011). The maximum reductions of the faecal egg counts were 50.3 and 93.6 % for both treatments, respectively, whereas the percent reductions of the total number of L(3) larvae were 80 % (the extract) and 85.6 % (levamisole phosphate). There was no difference between extract-treated and untreated goats with respect to worm burden, and the percent reductions were 28.8 and 63.4 % for *Oesophagostomum columbianum* and *Trichostrongylus colubriformis*, respectively. No reduction was detected for the *Haemonchus contortus*.

Studies showed that *A. sisalana* extracts exhibited activity in vitro against gastrointestinal nematodes (eggs and larva) of goats (Botura et al. 2013). The EC₅₀ values for egg hatching inhibition 4.7, 0.1 and 0.05 mg/ml for EE (ethyl acetate extract), EA (aqueous extract) and FF (flavonoid fraction), respectively. The SF (saponin fraction) showed no ovicidal activity. The percent efficacies that were observed for the larval migration

inhibition were 50.3, 33.2 and 64.1 % for the AE, EE and SF, respectively. The FF fraction did not show activity against the larvae.

Antimicrobial Activity

Crude methanol extracts of only *Agave sisalana* toothbrush sticks showed antibacterial activity against *Staphylococcus aureus* and *Bacillus cereus* (Kassu et al. 1999). The extract at concentrations up to 500 µg/ml showed weak toxicity to brine shrimp.

Sisal extract was found to have antibacterial activity against *Escherichia coli* and *Bacillus stearothermophilus* and is used as an ingredient in petroleum jelly (Zwane et al. 2010). Crude methanol and aqueous *A. sisalana* extract showed antibacterial activity against the tested bacteria (Hammuel et al. 2011; Ade-Ajayi et al. 2011). The methanol extract of sisal juice exerted more effect on *Shigella dysenteriae*, *Pseudomonas aeruginosa*, *Enterococcus faecalis* and *Candida albicans* and least on *Bacillus atrophaeus* than the aqueous extract. The minimum inhibitory concentration (MIC) of both the methanol and aqueous extract was between 10 and 20 mg/ml, and the minimum bactericidal concentration (MBC) was between 20 and 40 mg/ml for both extracts. Different results were obtained in another study wherein the hydroalcoholic extract obtained from sisal leaves and sisal waste showed significant inhibition of *Candida albicans* but was inactive against three strains of *Staphylococcus aureus*, two strains of *Escherichia coli*, and a strain of *Micrococcus luteus*, *Bacillus cereus*, *Pseudomonas aeruginosa* and *Salmonella choleraesuis* (Santos et al. 2011). The methanol extract of leaves showed weaker reduction in the inhibitory action of *C. albicans* when compared with the above extracts and was also inert against the other microorganisms tested.

Ecbolic Activity

Studies by Sharaf and Zahran (1967) found that *A. sisalana* juice stimulated intestinal and uterine

musculature in dogs, mouse and rat; lowered blood pressure in dogs; and produced abortion in pregnant mice and rats. The results suggested Agave juice to be a uterine stimulant, emmenagogue, laxative and hypotensive drug.

Larvicidal Activity

Waste residue of sisal leaves was found to have larvicidal activity (Pizarro et al. 1999). Various components of the extract were effective in eliminating mosquito larvae; the LC_{50} values for *Aedes aegypti* was 322 and 183 ppm for *Culex quinquefasciatus*. Under field conditions, the formulation used at 100 ppm caused 100 % mortality of *C. quinquefasciatus* larvae after 3–4 days.

Allergy Problem

Sisal processing was found to be associated with increased risk of immunoglobulin E (IgE) sensitization (Kayumba et al. 2008). Significantly higher prevalence of positive skin prick tested (SPTs) to sisal was found among 74 % of sisal workers compared to 17 % among controls. All exposed workers had elevated IgE levels, and 27 % of tested sera had elevated sisal specific IgE. A high prevalence of respiratory symptoms was found in both sensitized and non-sensitized sisal workers. In further studies, Kayumba et al. (2011) conducted a cross-sectional study on chronic respiratory symptoms and lung function among male Tanzanian sisal processing workers from six sisal estates in 2006. They found that chronic cough and chest tightness were experienced by 38 and 68 % of workers in brushing departments, 20 and 6 % of workers in decortication, and 7 and 0 % of security workers, respectively. A reduced FEV(1) [forced expiratory volume in 1 s]/FVC (forced ventilatory capacity) ratio related to years of work was found among workers in brushing departments when adjusting for age, smoking, previous respiratory illnesses and body mass index, using regression analyses. The overall results indicated a relationship between work in sisal brushing departments and the development of obstructive lung disorders.

Traditional Medicinal Uses

In northern Morocco, leaf juice is used as a wash for skin diseases (El-Hilaly et al. 2003). It is also used for syphilis, pulmonary tuberculosis, and jaundice and as a laxative. In Angola, lightly heated pounded roots are used for intercostal pain; also pounded plant is used for nephralgia (Bossard 1996). In Kenya, sap from young leaves is used as disinfectant, for stomachache, and for constipation (Kokwaro 1976; Phanuel et al. 2010); fibres are used as bandage (Njoroge and Bussmann 2007); and roasted leaves are used for burns (Okello et al. 2010). In Bahamas, salted decoction of central bud is used for jaundice (Debnath et al. 2010). The plant sap has been used in Central America as a binding agent for powders used as poultices for wounds (Chevallier 1996). The plant is used internally for the treatment of indigestion, flatulence, constipation, jaundice and dysentery (Bown 1995). The water used for soaking Agave fibres is used as scalp disinfectant and tonic for thinning hair (Lust 1974).

Other Uses

Sisal is a valuable forage for honey bees because of its long flowering period and is also commonly planted as an ornamental plant for landscaping purposes in parks, gardens and homes. In India, sisal plant is extensively planted as hedges along railroads. Sisal is also planted as fencing, to mark field boundaries, and to stabilize soil. The long and straight inflorescence stalks are used for house construction, fencing and thatching. A very hard wax is obtained from the leaf cuticle, and pectin can be obtained from sisal leaves. *Agave sisalana* toothbrush sticks are commonly used by people who cannot afford to buy the commercial toothbrush and toothpaste in Ethiopia (Kassu et al. 1999).

D-mannitol isolated from *Agave sisalana* is a compound widely used in the pharmaceutical industry and is also used as a raw material for producing several types of polymers (Branco et al. 2010). The steroidal saponins, tigogenin and hecogenin, extracted from the waste residues

after production of sisal fibres from *A. sisalana* and *A. americana*, are important raw materials in the synthesis of steroid hormones, as starting materials in the production of corticosteroids (cortisone, cortisol, prednisolone, prednisone, dexamethasone, betamethasone, triamcinolone, etc.) (Escamilla-Treviño 2012). Utilization of sisal waste for mushroom growing, animal feed, and production of biogas had already been demonstrated at pilot scale in Tanzania (Bisanda and Enock 2003). Several edible mushrooms, notably *Coprinus cinereus*, grow in large quantities on the waste heaps of sisal factories in Tanzania and provide a year-round source of food (Oyen 2011).

Sisal fibre is one of the four most common widely used natural fibres, and it accounts for half of total production of textile fibres (Mukherjee and Sat 1984). Sisal fibre is used for the manufacture of ropes for use in the marine industry and agriculture, coarse fabrics, geotextiles, sisal wall coverings, carpets, twines, macramé, nets, upholstery padding, carpet padding, baskets, mats, blankets, jewellery, sandals, clothing, mattresses, fish stringers, biodegradable storage bags for agricultural produce, musical instruments, ceremonial objects, paper pulp, construction materials, cat scratching posts and dart boards (Usher 1974; Chand et al. 1984; Mukherjee and Satyanarayana 1984; Li et al. 2000) and as raw material for medium-density fibreboard production (Gillah et al. 1998). New applications for sisal fibre is being focused on the manufacture of flat corrugated roofing panels that are strong and cheap with good fire resistance and natural fibre-reinforced composites (Chand et al. 1984; Mukherjee and Satyanarayana 1984; Rowell 1992; Joseph et al. 1996; Li et al. 2000; Mu et al. 2009; Barreto et al. 2011). The matrix used in sisal fibre-reinforced composites include thermoplastics (polyethylene, polypropylene, polystyrene, PVC, etc.), thermosets (epoxy, polyester, etc.), rubber (natural rubber, styrene-butadiene rubber, etc.), gypsum and cement (Li et al. 2000). Sisal fibre is an effective reinforcement of polymer, rubber, gypsum and cement matrices. This has created a range of technological applications beyond its traditional usage as ropes, carpets, mats, etc. Research showed that biopolymers and natural fibres like sisal (*A. sisalana*) can be used to

develop biocomposite plate materials that can be externally coated with calcium phosphate and hydroxyapatite (hybrid) composite and used for inside fixation and also external fixation of fractured bones (Chandramohan and Marimuthu 2011). Sisal fibre is also used for making specialty papers, such as cigarette paper, newsprint, bag paper, carbon paper, safety and banknote paper, filter paper, tea bags and biodegradable storage bags for agricultural produce. Whole leaves and sisal waste material may also be used as a source of pulp for papermaking.

Waste material after fibre extraction and boles remaining at the end of the life cycle of a crop may serve as animal feed, either directly or after ensilage. Studies showed dried sisal pulp to be a good feed for sheep, and that their performance improved increasingly when this was used to replace barley straw in the diet (Gebremariam and Machin 2008). Sisal pulp had a crude protein of 7.3 %, crude fibre of 15.2 % and NFE (nitrogen-free extract) of 59.6 %. The dry matter digestibility was 68.5 %, and organic matter digestibility was 73.3 %.

Some *Agave* species including *A. sisalana* have a real potential to compete economically with other bioenergy crops for biofuel production (Davis et al. 2011; Escamilla-Treviño 2012). Being CAM (crassulacean acid metabolism) plants, they have high water-use efficiency and can be grown in semiarid areas too dry to grow food crops, possessing potential for producing biomass feedstocks in large amounts while minimizing competition with the food supply. They contain cellulose and hemicelluloses as the main components in the cell wall that can be hydrolyzed to simple sugars for further fermentation to produce ethanol or other liquid biofuel. Theoretically, a crop area alone could provide 6.1 billion l of ethanol if *Agave* were re-established as a bioenergy feedstock without causing indirect land use change (Davis et al. 2011).

Agave sisalana is also used in veterinary for animal diseases. In western Kenya, leaf preparations are used to treat gastrointestinal diseases, (diarrhoea, unthriftiness, drooping wings) in poultry (Okitoi et al. 2007). Juice of fleshy leaves or leaves and stems fermented in urine is applied on the animal's body surface against ticks (Wanzala et al.

2012). Aqueous extract made from chopped leaves and stem is applied on the animal's body surface while still fresh, or leaves are dried and ground to flour and applied on the animal's body surface as dust. Dried leaves are also used as fumigation against ticks. In Kivu, Democratic Republic of Congo, Agave leaves mixed with leaves of other plants are burn, and the ashes mixed in palm oil is applied to wounds on animals (Balagizi et al. 2005). In Zambia, leaves and stalks are pounded and added to drinking water to control Newcastle disease in poultry (Alders 2001). In Ethiopia, the roots are used to control blackleg in animals (Giday et al. 2003).

Comments

According to FAO Stat (2012), the leading producers (tonnes production) of sisal in 2011 are Brazil 283,797; Kenya 27,560; Tanzania 24,828; Mexico 20,113; Madagascar 18,937; and China 14,683.

Turkish: Dağ Sümbülü

Welsh: Clychau Dulas

Origin/Distribution

The species is native to southwestern Asia and the Mediterranean region.

Agroecology

The species occurs naturally in dry grassland, foothills, grassy mountain slopes and forests in its native range. The plant is commonly cultivated in lawns, borders, rock gardens and containers. It prefers well-drained, moderately moist sandy soil that is acid to neutral and not too rich. It can be grown in full sun to partial shade and

requires little feeding or watering in the summer; it flowers in spring. It is frost tolerant, withstanding temperatures down to -23°C .

Edible Plant Parts and Uses

The blue flower buds and bulbs of these plants are featured heavily in Mediterranean cuisine, particularly in dishes originating from southern Italy. Muscari flowers have a sweet, nutlike flavour and are used as flavoring, while the bulb tastes like a slightly bitter onion and garlic hybrid (Wright 2001; Facciola 1990). The flowers and flower buds can be pickled in vinegar. The different parts of this plant including the leaves are edible raw, boiled, grilled or pickled.

Botany

The herbaceous plant grows to 25 cm with ovoid bulbs 2–3 by 2–2.5 cm covered with dark brown tunic. Leaves 3–6, linear to lanceolate, 5–35 cm long and 0.25–0.75 cm wide. Scape to 25 cm long. Inflorescence racemose with 20–40 blue to purplish-blue flowers (Plates 1, 2). Flowers on 1–5 mm nodding pedicels, sterile flowers smaller and paler than fertile ones. Perianth tube 3–7 mm, ovoid to oblong-urceolate or cylindric, teeth white, stamens biseriate at middle of tube. Capsule 5–9 × 8–10 mm, broadly ovate to orbicular, tip rounded or shortly emarginated.

Plate 1 Grape hyacinth plant

Plate 2 Grape-like flowers in a racemose inflorescence

Nutritive/Medicinal Properties

From the bulbs of *Muscari neglectum*, a scillascillinoid homoisoflavanone was isolated and elucidated as 2',5-dihydroxy-4',7-dimethoxyspirol [2*H*-1-benzopyran-3(4*H*),7'-bicyclo[4.2.0]octa[1,3,5]-trien]-4-one (Barone et al. 1988). Also isolated were scillascillin and four known 3-benzyl-4-chromanones including 4'-demethyl-3,9-dihydropunctatin; 5,7-dimethoxy-3(4-methoxybenzyl)chroman-4-one. From the bulbs, two 3-benzylidene-4-chromanones were isolated, namely, 5,7-dihydroxy-6-methoxy-3-(3,4-dihydroxybenzylidene)chromane-4-one and 7-hydroxy-5-methoxy-3-(3,4-dihydroxybenzylidene)chromane-4-one together with known homoisoflavanone (Mašterová et al. 1991). Uracil and succinic acid were isolated from the aerial parts.

Homoisoflavanoid compounds had been reported to exhibit antiinflammatory, estrogenic, antiestrogenic, anticancer and angioprotective bioactivities (Jiang et al. 2007).

The homoisoflavanoids from *Muscari racemosum* were found to have antioxidative property (Juránek et al. 1993). The extract of the bulb rich in 3-benzylidene-4-chromanones (homoisoflavanoids) was found to have antimutagenic and anticlastogenic properties using the Ames assay on four bacterial strains *Salmonella typhimurium* TA97, TA98, TA100, TA102, in the toxicity and mutagenicity/antimutagenicity assay on the yeast strain *Saccharomyces cerevisiae* D7, and in the simultaneous phytotoxicity and clastogenicity/anticlastogenicity assay on *Vicia sativa* (Miadoková et al. 2002). The homoisoflavanoid fraction obtained from the *Muscari racemosum* bulb ether extract (MRBEE) exhibited a dose-dependent estrogenic activity by inducing proliferation of MCF7 cells (Urbancíková et al. 2002). In the presence of estradiol, MRBEE exhibited a dose-dependent antiestrogenic activity.

Other Uses

The plant is planted as ornamental in borders, containers and rock gardens and flowers profusely in spring.

Comments

The plant is propagated from seeds, small or large bulbs or by division of offsets.

Origin/Distribution

It is indigenous to Central and southern Mexico. The plant was distributed all over the world as an ornamental and is grown in tropical, subtropical and subtemperate areas. Kenya and Egypt are the leading producers of tuberose for the export market.

Agroecology

Tuberose grows best in mild climate without extremes of high or low temperatures. It thrives in warm humid areas with mean temperatures of 20–32 °C. It is sensitive to low temperatures and frost. High temperatures close to 40 °C reduces flower spike length and quality. Tuberose prefers a sunny position. Although it can grow in a wide range of soils including saline and alkaline soils, it prefers well-drained and aerated sandy loams rich in organic matter with pH of 6–7.5. It requires copious watering during the growth stage. The plant can also be grown in pots and in greenhouses in temperate areas.

Edible Plant Parts and Uses

The flowers are eaten as vegetables (Burkill 1966; Uphof 1968; Tanaka 1976; Kunkel 1984; Facciola 1990; Roberts 2000). In Java, the Chinese cook the flowers in a kind of soup. The cooked flowers are also added to the substrate of ‘kecap’, an Indonesian soy sauce. Fragrant flowers are added along with other ingredients to the favourite beverage prepared from chocolate and served either hot or cold as desired. The flowers are the source of tuberose-flower water.

Botany

Tuberose is a hardy perennial, erect herb, 45–70 cm high with tuberose rootstock and shallow adventitious roots and a short stem. It has elongated linear, bright green leaves clustered at

the base of the plant (Plate 1) and smaller clasping leaves along the stem. The flowers in a long (up to 45 cm), simple, unbranched terminal racemous spike with 4–6, waxy, fragrant white flowers borne in pairs (Plate 2). The perianth is tubular or funnel-shaped with short subequal, curved oblong-lanceolate tepals, 10–15 mm long. Stamens 6 with filaments adnate to the upper part

Plate 1 Clumps of tuberose plants

Plate 2 Unbranched terminal spike with white flowers

of the perianth tube, anthers dorsifixed. Ovary 3-loculed with numerous ovules, stigmas 3 ovate. Fruit a capsule.

Besides the normal 'single-tepal' flower, 'double-tepal' tuberose flowers have been developed in white and various colours such as reddish purple, pale purple, pale red, reddish pink, yellow and orange (Huang et al. 2001a, b) and also tuberose with variegated yellow-striped leaves.

Nutritive/Medicinal Properties

Polianthes tuberosa tuber was found to contain lycorine, an alkaloid that causes vomiting (Gorter 1919). A glucofructosan (Srinivasan and Bhatia 1954), transfructosidase (Bhatia and Srinivasan 1954) and sucrose (Wali and Hasan 1965) were found in the plant. Chandravadana et al. (1995) found indole in the absolute from various varieties and hybrids, varying in contents ranging from 0.36 to 2.15 %. Several steroid sapogenins, such as hecogenin, 9-dehydroxyhecogenin and tigogenin (Zhou et al. 1965), as well as glycosides, 29-hydroxystigmast-5-en-3 β -yl β -D-glucoside (Rashid et al. 1999), (22*S*)-2 β ,3 β ,22-trihydroxycholest-5-en-16 β -yl β -D-glucoside (Firdous et al. 1999b) and diribofuranosylethyleneglycol (Firdous et al. 1999a) and spirostanol pentaglycosides (Mimaki et al. 2002) were identified from the underground parts of *P. tuberosa*. Four new spirostanol saponins with five monosaccharides (1–4) were isolated from *P. tuberosa* underground parts (Mimaki et al. 2002). Three glycosides and a long-chain alcohol were isolated from the bulbs of *Polianthes tuberosa*; these were identified as 3,29-dihydroxystigmast-5-ene-3-*O*- β -D-galactopyranoside (1), ethyl β -D-galactopyranoside (2), ethyl- α -D-galactopyranoside (3) and 1-tricosanol (4) (Khan et al. 2002). None of the compounds showed any significant cytotoxicity, antibacterial and antifungal activities.

A bisdesmosidic cholestane glycoside (1) and three new spirostanol saponins (2–4), along with a known cholestane glycoside, were isolated from the aerial parts of *Polianthes tuberosa* (Mimaki et al. 2000).

A new cholestane glycoside, (22*S*)-cholest-5-en-1 β ,3 β ,16 β ,22,25-pentaol 1-*O*- β -D-GLUCOPYRANOSYL-16-*O*- β -D-apiofuranoside which was named tuberoside A, together with two known cholestane glycosides were isolated from the tubers of *Polianthes tuberosa* (Jin et al. 2003a). The two known cholestane glycoside 1 and 2 were identified as (22*S*)-cholest-5-en-1B, 3B, 16 B, 22-tetraol 1-*O*-B-D-glucopyranosyl-16-*O*-B-D-apiofuranoside (Mimaki et al. 2000) and (22*S*)-cholest-5-en-1B, 3B, 16 B, 22-tetraol 3, 16-di-*O*-B-D-glucopyranoside (Mimaki et al. 1995), respectively.

Six new steroid glycosides comprising two spirostanols, polianthosides B and C (1, 2) and four furostanols, polianthosides D–G (3–6) together with eight known saponins (7–14), were isolated from the fresh tubers of *P. tuberosa* (Jin et al. 2004). Polianthoside B (1) was characterised as tigogenin 3-*O*- β -D-xylopyranosyl-(1 \rightarrow 3)- β -D-glucopyranosyl-(1 \rightarrow 2)-[β -D-glucopyranosyl-(1 \rightarrow 3)]- β -D-glucopyranosyl-(1 \rightarrow 4)- β -D-galactopyranoside and polianthoside C (2) as tigogenin 3-*O*- β -D-glucopyranosyl-(1 \rightarrow 3)- β -D-glucopyranosyl-(1 \rightarrow 2)-[β -D-glucopyranosyl-(1 \rightarrow 3)]- β -D-glucopyranosyl-(1 \rightarrow 4)- β -D-galactopyranoside. Polianthoside D (3) was elucidated as 26-*O*- β -D-glucopyranosyl-(25*R*)-5*R*-furost-3 β ,22*R*,-26-triol-12-one 3-*O*- β -D-glucopyranosyl-(1 \rightarrow 2)-[β -D-xylopyranosyl-(1 \rightarrow 3)]- β -D-glucopyranosyl-(1 \rightarrow 4)- β -D-galactopyranoside. Polianthoside E (4) was elucidated as 26-*O*- β -D-glucopyranosyl-(25*R*)-5*R*-furost-3 β ,22*R*,-26-triol-12-one 3-*O*- β -D-xylopyranosyl-(1 \rightarrow 3)- β -D-glucopyranosyl-(1 \rightarrow 2)-[β -D-xylopyranosyl-(1 \rightarrow 3)]- β -D-glucopyranosyl-(1 \rightarrow 4)- β -D-galactopyranoside. Polianthoside F (5) was deduced to be as 26-*O*- β -D-glucopyranosyl-(25*R*)-5*R*-furost-3 β ,22*R*,-26-triol 3-*O*- β -D-xylopyranosyl-(1 \rightarrow 3)- β -D-glucopyranosyl-(1 \rightarrow 2)-[β -D-xylopyranosyl-(1 \rightarrow 3)]- β -D-glucopyranosyl-(1 \rightarrow 4)- β -D-galactopyranoside and polianthoside G (6) deduced to be 26-*O*- β -D-glucopyranosyl-(25*R*)-5*R*-furost-3 β ,22*R*,-26-triol 3-*O*- β -D-xylopyranosyl-(1 \rightarrow 3)- β -D-glucopyranosyl-(1 \rightarrow 2)-[β -D-glucopyranosyl-(1 \rightarrow 3)]- β -D-glucopyranosyl-(1 \rightarrow 4)- β -D-galactopyranoside. The eight known steroid saponins were identified as hecogenin 3-*O*- β -D-

glucopyranosyl-(1 → 2)-β-D-glucopyranosyl-(1 → 4)-β-D-galactopyranoside (7) (Xu et al. 2000), hecogenin 3-*O*-β-D-glucopyranosyl-(1 → 2)-[β-D-xylopyranosyl-(1 → 3)]-β-D-glucopyranosyl-(1 → 4)-β-D-galactopyranoside (8) (Mimaki et al. 1995), hecogenin 3-*O*-β-D-xylopyranosyl-(1 → 3)-β-D-glucopyranosyl-(1 → 2)-[β-D-xylopyranosyl-(1 → 3)]-β-D-glucopyranosyl-(1 → 4)-β-D-galactopyranoside (9) (Mimaki et al. 2000), agamenoside F (10) (Jin et al. 2003b), tigogenin 3-*O*-β-D-glucopyranosyl-(1 → 2)-[β-D-xylopyranosyl-(1 → 3)]-β-D-glucopyranosyl-(1 → 4)-β-D-galactopyranoside (11) (Wang et al. 1996), tigogenin 3-*O*-β-D-xylopyranosyl-(1 → 3)-β-D-glucopyranosyl-(1 → 2)-[β-D-xylopyranosyl-(1 → 3)]-β-D-glucopyranosyl-(1 → 4)-β-D-galactopyranoside (12) (Mimaki et al. 2000), chlorogenin 3-*O*-β-D-xylopyranosyl-(1 → 3)-β-D-glucopyranosyl-(1 → 2)-[β-D-xylopyranosyl-(1 → 3)]-β-D-glucopyranosyl-(1 → 4)-β-D-galactopyranoside (13) (Mimaki et al. 2000) and 26-*O*-β-D-glucopyranosyl-(25*R*)-5*R*-furost-3β,22*R*,-26-triol 3-*O*-β-D-glucopyranosyl-(1 → 2)-[β-D-xylopyranosyl-(1 → 3)]-β-D-glucopyranosyl-(1 → 4)-β-D-galactopyranoside (utroside B) (14) (Sharma et al. 1983), respectively.

Six unsaturated γ-lactones, (Z)-5-octen-4-olide (1), (Z)-5-decen-4-olide (2), (Z)-6-nonen-4-olide (3), (Z)-6-dodecen-4-olide (4), (Z, Z)-6,9-dodecadien-4-olide (5) and tuberoside (6), were identified in tuberoside absolute (from *Polianthes tuberosa*) (Maurer and Hauser 1982).

Seventeen volatile components were identified from *P. tuberosa*; the major components were benzyl benzoate (16.76 %), *trans*-methyl isoeugenol (15.3 %) and ethyl myristate (14.0 %) (Wahba et al. 1998). The presence of the N-containing compound methyl anthranilate, constituting 7.1 %, was confirmed. Volatiles of *Polianthes tuberosa* showed no significant increase in blood glucose, blood urea nitrogen, serum glutamic-oxalacetic transaminase (SGOT) and serum glutamic pyruvic transaminase (SGPT) when applied to the skin of rabbits indicating that it had no subacute dermal toxicity.

Percentage yields of tuberoside oil from cold enfleurage, hot enfleurage, hexane and petroleum ether extractions of double-flower variety

of tuberoside (*Polianthes tuberosa*) were 0.3137, 6.5808, 0.0279, and 0.0182 %, respectively (Rakthaworn et al. 2009). The main chemical component detected in both enfleurage absolutes was methyl benzoate, while benzyl benzoate and pentacosane were found to be the main chemical components in hexane and petroleum ether absolutes, respectively. Ten compounds were detected in cold enfleurage absolute with the major components being methyl benzoate (30.17 %), benzyl benzoate (23.64 %), 7-decen-5-olide (13.33 %) and methyl salicylate (12.11 %). Other compounds included (*E*)-methyl isoeugenol (8.83 %), methyl anthranilate (4.45 %), (Z)-β-farnesene (2.43 %), methyl eugenol (1.80 %), indole (1.78 %) and (*E*)-citral (1.47 %). Ten chemical constituents were also detected in the hot enfleurage absolute, with methyl benzoate being the main component again, but with a higher percentage yield (44.85 %) followed by (Z)-3-hexenyl 2-oxopropanoate (27.38 %) as major components. Other components included methyl salicylate (7.18 %), 1-tetradecene (4.15 %), benzyl benzoate (3.75 %), (Z)-nerolidol (3.35 %), 1-hexadecene (3.39 %), 2,4-decadien-1-al (2.91 %), (*E*)-methyl isoeugenol (1.78 %) and 2-heptadecanone (1.26 %). Fourteen chemicals were detected in the tuberoside hexane absolute with benzyl benzoate (24.25 %), pentacosane (19.23 %) and 7-decen-5-olide (14.96 %) as the major components. Others included 1-hexadecene (8.85 %), 2,4-di-*tert*-butylphenol (8.36 %), eicosanol (4.96 %), heptacosane (4.60 %), (Z)-3-hexenyl 2-oxopropanoate (3.70 %), tricosane (2.47 %), methyl isoeugenol (2.32 %), α-farnesol (1.94 %), (*E*)-methyl isoeugenol (1.89 %), benzyl salicylate (1.39 %) and methyl eugenol (1.07 %). There were 14 chemicals identified in the petroleum ether absolute. The main components were pentacosane (29.44 %), 7-decen-5-olide (18.13 %) and heptacosane (12.53 %). Others included benzyl benzoate (10.28 %), (*E*)-methyl isoeugenol (6.05 %), methyl isoeugenol (4.85 %), methyl anthranilate (4.15 %), α-farnesol (4.06 %), tricosane (3.65 %), methyl eugenol (1.89 %), 1-hexadecene (1.69 %), benzyl salicylate

(1.34 %), 1-tetradecene (0.98 %) and (Z)-methyl isoeugenol (0.96 %). Petroleum ether extracted more wax, for example, pentacosane and heptacosane, from plant cells than hexane.

Coloured varieties of *P. tuberosa* and its hybrids with *P. howardii* were found to contain anthocyanins and carotenoids in their petals (Huang et al. 2001a, b). White-flowered varieties contained no anthocyanin. The main anthocyanidin in the petals of coloured flowers was cyanidin, and some hybrids also contained delphinidin. Reddish purple or pale purple flower hybrids contained delphinidin glycoside with cyanidin glycoside, whereas only cyanidin glycosides were contained in the flowers of orange, pale red and reddish pink.

Soaking or spraying tuberose bulbs in solutions of bioregulators such as spermidine and ATP increases the contents of indoles, phenols, carotenoids, carbohydrate, essential oil and phytohormones (endogenous gibberellin (GA3), total cytokinins and abscisic acid (ABA)) of the tuberose plants (Lobna and Rawia 2011). Bioregulator treatment (100 ppm) augmented plants bulblets and flowering characteristics (number of bulblets, fresh and dry weights of bulblets, number of days to flowering, number of florets/spike, spike length, length of rachis and fresh and dry weights of spike).

A lactone-designated tuberculactone was isolated from tuberose leaves (Kaiser and Lamparsky 1976). Three flavonoid compounds isolated from the leaves of *P. tuberosa* were kaempferol, kaempferol-3-*O*-xyloside and kaempferol-3-4'-*O*-dixyloside (El-Moghazy et al. 1980). Rammamurthy et al. (2010) isolated 9,11dehydrohecogenin 3-*O*-glucose xylose galactoside, kaempferol-3-*O*-xyloside, α -D-glucoside and polianthosides B and C from *P. tuberosa* leaves.

Antimicrobial Activity

Both Gram-positive and Gram-negative bacteria were found susceptible to *P. tuberosa* flower essential oil (Lodhia et al. 2009).

Anticancer Activity

Four new spirostanol saponins isolated from tubers exhibited cytotoxic activities against HL-60 human promyelocytic leukaemia cells and HSC-2 human oral squamous cell carcinoma cells (Mimaki et al. 2002). Six new steroid glycosides comprising two spirostanols, polianthosides B and C (1, 2) and four furostanols, polianthosides D–G (3–6) together with eight known saponins (7–14), were isolated from the fresh tubers of *P. tuberosa* (Jin et al. 2004). Cytotoxicity activity of the isolated compounds against HeLa cells in terms of IC₅₀ values were polianthoside B >20 μ g/ml, polianthoside C >20 μ g/ml, furostanol polianthoside D 7.86 μ g/ml, furostanol polianthoside E 5.21 μ g/ml, furostanol polianthoside F 20 μ g/ml, furostanol polianthoside G 5.36 μ g/ml, furostanol polianthoside H 8.61 μ g/ml, saponin 9 8.17 μ g/ml, saponin 10 4.02 μ g/ml, saponin 11 3.54 μ g/ml, saponin 12 7.20 μ g/ml, saponin 13 7.50 μ g/ml, saponin 14 18.83 μ g/ml and cisplatin 0.75 μ g/ml. It was observed that most of the saponins (3, 4 and 7–10) with a carbonyl group at C-12 of the aglycone showed stronger cytotoxicities (IC₅₀ 4.02–8.61 μ g/ml) against HeLa cells than saponins 1, 2, 5 and 14, with no carbonyl group attached at the aglycone (IC₅₀ > 18.83 μ g/ml).

Molluscidal Activity

Powder of *Polianthes tuberosa* bulb and its saponins tigogenin and hecogenin caused a significant reduction in fecundity, hatchability and survival of young snails of *Lymnaea acuminata* (Singh et al. 1999). Exposure to sublethal concentration caused a small but significant reduction in protein, amino acids, nucleic acids and phosphatase activities in gonadal tissue of treated snails. Withdrawal after 7 days indicated that the effect of powder of *P. tuberosa* bulb, tigogenin and hecogenin on the reproduction and different biochemical parameters was reversible.

Immunosuppressive Activity

An acidic polysaccharide (ANK-102) produced by *P. tuberosa* cells in liquid culture was found to deteriorate resistance of mice to lethal infection of *Listeria monocytogenes* (Majima et al. 1995). Pretreatment with ANK-102 resulted in the accumulation of Mac 1 and Mac 2 positive cells in the peritoneal cavity of the infected animals and the reduction of Thy1.2 expression on the surface of the thymocytes.

Larvicidal and Deterrence Activity

Both crude and chloroform–methanol (1:1, v/v) extract of fresh mature *P. tuberosa* buds showed larvicidal activity against *Culex quinquefasciatus* (Rawani et al. 2012). The chloroform–methanol extract also showed biting deterrence activity against *Anopheles stephensi* and *Culex quinquefasciatus*.

Traditional Medicinal Uses

Tuberose has been reported to be used in traditional folk medicine (Burkill 1966; Perry 1980; Chopra et al. 1986; CSIR 1969; Jin et al. 2004; Kuppast et al. 2006; Stuart 2012).

In Chinese folk medicine, the tubers are used for the treatment of acute infectious diseases and pyrogenic inflammations, burns and swellings. The tubers are also considered emetic antispasmodic and diuretic. The tubers are dried, powdered and used as a remedy for gonorrhoea and used with turmeric for curing rashes in infants and wound healing in India and also used to treat malaria. Poultice of the tubers are used as maturative in the formation of pus in boils or abscesses. In aromatherapy, the warm and seductive scent of the tuberose oil is useful as a hypnotic for women suffering from insomnia and depressed with low sexual drive.

Other Uses

Tuberose is gaining in popularity and importance as an ornamental in Asia. Besides the normal ‘single-tepal’ flower, tuberose is available as

‘double-tepal’ tuberose flowers and in various colours such as reddish purple, pale purple, pale red, reddish pink, yellow and orange (Huang et al. 2001a, b) and tuberose with variegated yellow-striped leaves.

Tuberose flowers are the source of the high-grade tuberose oil which remains today as one of the most expensive of the perfumer’s raw material. Flowers are used for artistic garlands, leis, floral ornaments, bouquets and buttonholes. The long fragrant flower spikes are excellent as cut flowers for table decoration with a long vase-life. In Malaysia, Chinese ladies make chaplets of the flowers for binding the hair. Tuberose flowers were considered a funeral flower in Victorian times. The Chinese used the cut flowers on the altars for religious and ancestral worships.

Tuberose absolute (100 % tuberose oil) showed only mild fungicidal activity at a concentration of 500 mg/l against *Colletotrichum gloeosporioides* (Nidiry and Babu 2005). However, three constituents present in the absolute, namely, geraniol, indole and methyl anthranilate, exhibited significant activity showing total inhibition of the mycelial growth at this concentration.

Comments

The quality and vase-life of tuberose flowers were improved greatly by harvesting at tight bud stage and pulsing cut flower stems in silver nitrate (AgNO_3), silver thiosulfate (STS) chemicals or a solution containing sucrose (Bakhsh et al. 1999).

Family

Asparagaceae

Common/English Names

Adam's Needle, Adam's Needle Yucca, Beargrass, Common Yucca, Filament Yucca, Silkgrass, Spoonleaf Yucca, Desert Candle, Needle Palm

Vernacular Names

Czech: Juka Vlákniť

Danish: Palmelilje, Trævlet Palmelilje

Eastonian: Kiuline Tääkliilia

French: Yucca

German: Fädige Palmlilie, Yucca

Hungarian: Kerti Jukka, Pálmaliliom

Norwegian: Plamelilje, Yucca

Polish: Juka Karolińska; Jukka Karolińska; Jukka Nitkowata; Jukka Ogrodowa

Spanish: Yuca

Swedish: Fiberpalmlilja

Origin/Distribution

The plant is a native of southeastern N. America to Mexico. It has been introduced and become naturalized in Europe.

Agroecology

In its native range, it occurs in sand dunes, waste ground and pine forests along the coastal plain. The plant thrives in sandy to sandy loam soils in full sun and is very drought tolerant and do well in outdoor container even without supplementary irrigation.

Edible Plant Parts and Uses

Flowers are eaten fresh and raw, cooked or dried, crushed and used as flavouring (Kunkel 1984; Bird 1990; McPherson 2007). Flowers can be added to salad (Facciola 1990). Some common recipes include yucca flower soup, stuffed yucca flowers

and apple crumble pie (Roberts 2000). Another recipe is braised yucca flowers with peas (Belsinger 1990). Flowering stem is cooked and used like asparagus (Bird 1990). The fruits are eaten raw or cooked (Uphof 1968; Usher 1974; Facciola 1990). The fruit is often dried for winter use.

Botany

An acaulescent herbaceous perennial 1–4 m high (Plate 1). Leaves basal, strap-like, 2–4 cm wide and 0.6–1 m long, all originating from a point in the form of a rosette. Leaf lamina occasionally erect, proximal leaves often becoming reflexed near middle, lanceolate, flattened, abruptly narrowed and furrowed to apex, thin, widest near middle, usually soft and limp, scabrous, margins entire, long and curling, filiferous (producing threads) (Plate 2). The inflorescence paniculate, showy and borne on an erect scape 1–3 m high (Plates 1 and 3). Flowers up to two dozen, pendent,

perianth globose; tepals distinct, creamy-white to nearly white, ovate, 5–7×2–3 cm, glabrous with short-acuminate apex; filaments shorter than pistil; pistil 1.5–3.8 cm with lobed stigmas (Plates 3, 4 and 5). Fruits erect, capsular, dehiscent, oblong, 3.8–5 by 2 cm. Seeds dull black, thin, 6 mm across.

Plate 2 Strap-like leaves with threads (filiferous)

Plate 1 Yucca plant with 1–3 m long flowering scape

Plate 3 Flowering spike with paniculate branching

Plate 4 Pendant flowers with creamy-white tepals

Plate 5 Close view of flowers

Nutritive/Medicinal Properties

The roots of *Yucca filamentosa* were found to contain steroid saponins, steroid glycosides (Chernoff et al. 1917; Wells 1935; Kintya et al. 1972; Lazur'evskiĭ et al. 1975; Dragalin and Kintya 1975) and inulin (Wells 1935). Chernoff et al. (1917) isolated a saponin $C_{24}H_{40}O_{14}$ from

the rootstock of *Y. filamentosa* which on hydrolysis yielded a sapogenin. From the roots and leaves of *Yucca filamentosa*, steroidal saponins sarsapogenin, hecogenin, tigogenin and chlorogenin and glycosides were isolated (Kintya et al. 1972). Glycoside A was identified as trillin, and glycoside B designated as yuccoside B. Two new saponins, yuccoside C and protoyuccoside C, were isolated from the methanolic extract of *Yucca filamentosa* root (Dragalin and Kintya 1975). The structure of yuccoside C was elucidated as 3-*O*-[α -D-galactopyranosyl-(1 \rightarrow 2)- β -D-glucopyranosyl-(1 \rightarrow 4)- β -D-glucopyranosyl]-(25*S*)-5 β -spirostan-3 β -ol, whereas protoyuccoside C was 3-*O*-[α -D-galactopyranosyl-(1 \rightarrow 2)- β -D-glucopyranosyl-(1 \rightarrow 4)- β -D-glucopyranosyl]-26-*O*-[β -D-glucopyranosyl]-(25*S*)-5 β -furostan-3 β , 22 α , 26-triol. A new sarsapogenin glycoside, yuccoside E was isolated from the roots and elucidated as 3-*O*-{[*O*- α -D-galactopyranosyl(1 \rightarrow 2)]-[*O*- β -D-galactopyranosyl (1 \rightarrow 6)]-*O*- β -D-glucopyranosyl-(1 \rightarrow 4)- β -D-glucopyranosyl]-(25*S*), 5 β -spirostan-3 β -ol (Dragalin et al. 1975).

A new gitogenin-based steroidal saponin with a strong leishmanicidal activity was isolated by bioactivity-guided fractionation of the ethanolic extract of *Yucca filamentosa* leaves (Plock et al. 2001). The saponin was characterized as 3-*O*-((β -D-glucopyranosyl-(1 \rightarrow 3)- β -D-glucopyranosyl-(1 \rightarrow 2))(α -L-rhamnopyranosyl-(1 \rightarrow 4)- β -D-glucopyranosyl-(1 \rightarrow 3))- β -D-glucopyranosyl-(1 \rightarrow 4)- β -D-galactopyranosyl)-25*R*, 5 α -spirostan-2 α , 3 β -diol.

Twenty-one volatile scent compounds were identified in the floral headspace of *Yucca filamentosa* (Svensson et al. 2005). Most of the compounds could be categorized into two major classes: (1) homoterpenes derived from the sesquiterpene alcohol nerolidol and (2) long-chain aliphatic *n*-alkenes and alkanes with 15–19 carbons. The homoterpene *E*-4,8-dimethylnona-1,3,7-triene was produced in highest relative amounts in all populations (14.2–82.5 %), followed by a C_{11} alcohol (2.5–31.6 %) and 1-heptadecene (3.4–27.1 %). The remaining compounds typically comprised <10 % of the total sample. Two compounds were identified as di-oxygenated compounds with unknown structures.

Traditional Medicinal Uses

The genus *Yucca* (including *Y. filamentosa*) plant extracts were used to soothe joint pain, bleeding, urethral and prostate inflammations (Patel 2012). The leaves were brewed for common ailments as psoriasis, dandruff, hair loss and skin sores. Navajo Indians used it on sunburns and scratches. In northern New Mexico, traditional healers used a tea from the leaves and roots to treat asthma and headache. The Catawba, Cherokee, Nanticoke and other Native American tribes used *Yucca filamentosa* as medicines and soap. The roots were crushed to make poultice for wound healing and were used to cure gonorrhoea and rheumatism.

Other Uses

Y. filamentosa is excellent ornamental in rock gardens and as an accent among other perennials in natural areas and in mixed borders. It combines well with Agaves, grasses, cactus and palms to create low-maintenance xeriscapes of interesting textures and forms.

The leaves are used as paint brushes (Balls 1962). A fibre obtained from the leaves is used for making ropes, cloth, baskets and mats (Uphof 1968; Usher 1974). The fibre can also be used for making cream paper (Bell 1988). The roots are rich in saponins and can be used as a soap substitute for washing the hair, body and clothing (Uphof 1968; Usher 1974).

Comments

The plant is propagated by seeds, root cuttings and offshoots. Botanists report that *Yucca filamentosa* and *Y. flaccida* are very closely related and perhaps are not distinct species.

Origin/Distribution

The plant is indigenous to temperate and alpine areas in Eurasia, including most of Europe and many parts of Asia (i.e., from Turkey eastwards to Siberia and northwestern India). It has been introduced into North America, China, New Zealand and Australia.

Agroecology

Yarrow is a cool climate plant; it is occasionally grown in the cooler highland parts of subtropical regions. In its native range, it grows at low or high altitudes, up to 3,500 m above sea level. It grows in disturbed habitats, neglected gardens, waste areas, grasslands, woodlands, pastures, turfed areas, gullies and along roadsides in relatively moist locations. It grows in full sun to partial shade, on acidic to alkaline soils. It is frost and drought tolerant.

Edible Plant Parts and Uses

The flowers and leaves are edible (Uphof 1968; Grieve 1971; Facciola 1990; Roberts 2000; Schofield 2003). An aromatic tea is made from the dried flowers and leaves. An essential oil

extracted from the flowering heads is used as a flavouring for soft and alcoholic beverages. Yarrow flowers can be fried with butter sprinkled with sugar or orange juice. The bitter leaves are eaten raw or cooked as spinach or in soups and are best used when young and tender. They are also used in mixed salads. Yarrow leaves were part of a herbal mixture known as ‘gruit’ used in the flavouring and preservation of beer prior to the use of hops. The leaves are also used as a substitute for tobacco, nutmeg, cinnamon and hops.

Botany

An erect, branched herbaceous perennial, 20–100 cm high with rhizomatous or stoloniferous growth form and sparingly branched or unbranched tomentose or glabrous stems. Leaves are petiolate; large near the middle and bottom or sessile, cauline and smaller towards the tip. Leaf blades lanceolate or oblong-lanceolate, 3.5–25 cm × 5–3.5 cm, bipinnate or tripinnate, feathery and arranged spirally on the stem, glabrous to sparsely tomentose or densely lanate (Plates 1 and 2). Inflorescence heads 10 to >100, in terminal, simple or compound, slightly rounded or flat-topped corymbs on the expanded end (receptacle) of the flower stalk (Plate 2). Involucre oblong or subovoid with 20–30 phyllaries (involucral bracts) in 3 overlapping series, ovate to lanceolate and hairy. Each flower head (capitulum) contains ray florets (female) and disk florets (bisexual) which are white and cream to pink to deep purple (Plate 3). There are generally 3–8 ray florets that are ovate to round. Disk florets 10–20, at the centre of the flower head, tubular, and greyish white or cream. Fruit tiny, oblong achenes, 2 mm, with broadly winged margins and no pappus.

Nutritive/Medicinal Properties

Plant Phytochemicals

Sesquiterpenes and sesquiterpene lactones found in the leaf and flowering head included acetylbalchanolide, millefolide, and an unknown lactone

Plate 1 Juvenile plant with fine, feathery pinnately compound leaves

with mp 138 °C (Hochmannová et al. 1961); leucodin and achillin (Romo de Vivar and Olmos 1968); desacetylmaticarin, matricarin and millefin (Kasymov and Sidiyakin 1972); austriecin (deacetylmaticarin), millefin, 8-hydroxyachillin and an isomer of matricarin (Adekenov et al. 1979; Kasymov and Sidiyakin 1972); and artecanin, estafiatin, leucomisin and balchanolide from the plant (Konovalov and Chelombit'ko 1991). Achillicin, the major proazulene (prochamazulene) of *Achillea millefolium*, was isolated and identified as 8-acetoxyartabsin (Cuong et al. 1979a); chamazulene (2, 13–15) and chamaazulene carboxylic acid were also isolated (Cuong et al. 1979b). Other sesquiterpenes isolated included proazulenes, 8-acetoxyartabsin, 8-aneloxyartabsin, 2,3-dihydrodeacetoxymatricin, (Verzár-Petri et al. 1979a) and azulene (Verzár-Petri et al. 1979b). Three main azulenogene sesquiterpene lactones were isolated from *A. millefolium* plant and identified as 8-acetoxy-artabsine, 8-angeloxy-artabsine and

Plate 2 White-flowering head

Plate 3 Purple flowering head

2,3-dihydro-desavetoxy-matricin (Verzár-Petri et al. 1980). Ulubelen et al. (1990) isolated a new sesquiterpene lactone, achillifolin, together with known sesquiterpene lactones, dihydroparthanolide and dihydroreynosin, from the aerial parts. Known flavonoids, terpenoids and vanillic acid were also isolated. Ohir et al. (1991) isolated desacetylmaticarin, two sesquiterpene lactones of a new 3-oxa-guaianolide type, 8-acetyl egelolide and 8-angeloyl egelolide from the aerial parts. The structures of 8 α -angeloxy-, 8 α -tigloxy- and 8 α -acetoxo-10-epi-artabsin (achillicin) as well as of the respective 3-oxa-analogues were revised by Schröder et al. (1994). On the basis of 2D-NMR spectral data, it was shown unequivocally that these compounds were artabsin derivatives. *Achillea millefolium* was reported to contain α -peroxyachifolid, dehydromatricaria ester, pontica epoxide (Rücker et al. 1991; Hausen et al. 1991) and isoachifolidiene, a precursor of guaianolide peroxides (Rücker et al. 1992). Three

new antitumor sesquiterpenoids, achimillic acids A, B and C, were isolated as methyl esters from *Achillea millefolium* (Tozyo et al. 1994). Three new sesquiterpenes which were trivially named as sesquiterpene lactone esters A and B (1 and 2) and sesquiterpene lactone-diol (3) were isolated from the plant (Farooq et al. 2012).

Several species of the polyploid *A. millefolium* group, however, could be characterized by their distinct sesquiterpene pattern (Montsko et al. 2008). *A. millefolium* was characterized by the presence of 8-desacetylmaticarin, santonin, matricarin, achillicin and artabsins; *A. pratensis* by arglanin, 4-hydroxy-arglanin, santonin and santamarin; and *A. collina* by 8-desacetylmaticarin, santonin, matricarin, achillicin, 3-oxa-achillin, 8 α -angeloxy-artabsin, 8 α -angeloxy-3-oxa-artabsin, 8 α -tigloxy-artabsin and 8 α -tigloxy-3-oxa-artabsin.

Five sesquiterpenoid, i.e., seco-pseudo guaianolides (paulitin, isopaulitin, psilostachyin C,

desacetylmatricarin and sintenin) and five flavonoids (apigenin, luteolin, centaureidin, casticin and artemetin) were isolated and identified from the aerial parts of the *Achillea millefolium* aggregate (Csupor-Löffler et al. 2009). Flavonoids found in the plant included rutin, apigenin, luteolin and the 7-glucosides of apigenin and of luteolin, cosmosiin and luteolin 7-*O*- β -D-glucopyranoside (Kaloshina and Neshta 1973). The main flavonoid constituents of leaf and flower heads of *Achillea millefolium* subspecies were found to be apigenin and luteolin, mainly found as 7-*O*-glucosides and 7-malonylglucosides (Guédon et al. 1993). This represented the first report of flavone glycoside malonylesters in *Achillea* genus. White-flowering populations, i.e., the ssp. *millefolium* and *ceretanum*, showed a similar distribution of flavonoid compounds, whereas the presence of rutin in the leaves of the *alpestris* ssp. appeared to be characteristic. The flowering tops of this taxon were distinguished from the other two by their amount of schaftoside and isoschaftoside. The following sesquiterpenoids were isolated from *A. millefolium* group (*A. collina* and *A. pratensis*): achillicin, 8 α -tigloxy-artabsin, 8 α -angeloxy-artabsin, arglanin and santamarin (Glasl et al. 1999).

The flavonoids found in *A. millefolium* of the section *Millefolium* comprised of flavonoid aglycones and flavonoid glycosides—C-glycosylflavones, flavonol and flavones O-glycosides (Ivancheva et al. 2002). The flavonoid aglycones comprised large amounts of quercetagenin 3,6,7-trimethyl ether (chrysophenol-D), quercetagenin 3,6,7,3',4'-pentamethyl ether (artemetin); small amounts of scutellarein 6,7,4'-trimethyl ether (salvigenin), quercetagenin 3,6,4'-trimethyl ether (centaureidin); and traces of scutellarein 6-methyl ether (hispidulin), scutellarein 6,7-dimethyl ether (cirsimarín) and 6-hydroxyluteolin 6-methyl ether (nepetin). The flavonoid glycosides comprised small amounts of vitexin (5,7,4'-trihydroxyflavone-8-C-glycosyl), vicianine 2 (5,7,4'-trihydroxyflavone-6,6-di-C-glycosyl) and swertiponin (5,3',4'-trihydroxy-7-OMe flavone-6-C-glycosyl) and traces of swertisin (5,4'-dihydroxy-7-OMe flavone-6-C-glycosyl). The flavonol and flavones O-glycosides were large amount of quercetin-3-*O*-glycoside, small

amount of quercetin-3-*O*-rhamnoglucoside, and traces of luteolin-7-*O*-glycoside, diosmetin-7-*O*-glycoside and kaempferol-3-*O*-glycoside. The flavonoid casticin was isolated from *Achillea millefolium* (Haïdara et al. 2006). The following flavonoid compounds were found in *Achillea* species belonging to the *A. millefolium* L. group (Gherase et al. 2004): rutin, apigenin-7-*O*-glucoside and luteolin-7-*O*-glucoside were found in the methanol extract. The free aglycones, apigenin and luteolin, were also detected. Total phenolic contents reported for *A. millefolium* herb were 9.55 mg GAE/100 g DW (Wojdyło et al. 2007). Major phenolic compounds (mg/100 g DW) found were phenolic acids, 429 mg caffeic acid, 118 mg neochlorogenic acid and 35 mg ferulic acid, and flavonoids, 103 mg luteolin and 84.3 mg apigenin. The following phenolic compound were isolated from the methanol extract of *A. millefolium*: chlorogenic acid (1), rutin (2), luteolin 7-*O*-glucoside (3); 1,3-dicaffeoylquinic acid (4); 1,4-dicaffeoylquinic acid (5); 3,4-dicaffeoylquinic acid (6); apigenin 4'-*O*-glucoside (7); apigenin 7-*O*-glucoside (8); luteolin 4'-*O*-glucoside (9); and 3,5-dicaffeoylquinic acid (10) (Vitalini et al. 2011). Polyphenolic compounds (g/kg dry matter) in the aerial yarrow plant parts were determined as follows: chlorogenic acid 8.12 g, 3,5-DCQA (dicaffeoylquinic acid) 21.59 g, 1,5-DCQA 8.88 g, 4,5, DCQA 3.31 g, total caffeoyl derivatives 41.90 g, total dihydroxycinnamic acid derivatives 52.67 g, total flavonoids 12.92 g, total dihydroxycinnamic acid derivatives + flavonoids 65.59 g and total polyphenolic compounds 63.06 g (Fraisie et al. 2011).

Thirty-five compounds were isolated from various fractions of the ethanol extract of the dried plant material of *Achillea millefolium* (Tunón et al. 1994). From the C:1 fraction, adenine, betaine, betonicine, choline, homostachydrine, mandelonitrile glucoside, rutin, staydrine and trigonelline were isolated; from fraction C:2, caffeic acid, chlorogenic acid, ferulic acid, mandelic acid, salicylic acid and vanillic acid; and from fraction F:2, apigenin, capric acid methyl ester, caprylic acid methyl ester, carvacrol, eugenol, gallic acid, hydroquinone, isorhamnetin, linoleic acid ethyl ester, linoleic acid methyl

ester, linolenic acid methyl ester, luteolin, palmitic acid ethyl ester, palmitic acid methyl ester, phloroglucinol, protocatechuic acid, pyrocatechol, quercetin, tannic acid and undecylenic methyl ester were isolated.

Beta-sitosterol was identified as the major sterol and α -amyrin as the major triterpene of *A. millefolium* (Chandler et al. 1982b). The sterols stigmasterol, campesterol and cholesterol; and the triterpenes β -amyrin, taraxasterol and pseudotaraxasterol were also identified.

From above ground parts of *Achillea collina* within the *A. millefolium* group, proline, stachydrine, betonicine, betaine and choline were isolated as the major nitrogen containing compounds (Mehlführer et al. 1997). The TLC screening of 11 different species belonging to *A. millefolium* group showed qualitatively identical betaine patterns but quantitative differences were observed.

From the lipophilic extract of subterranean parts of *Achillea millefolium* s.str. 17 different alkamides together with (+)-sesamin were isolated and identified (Greger and Hofer 1989). Besides a rare decadienoic acid tyramide and the corresponding novel *p*-methoxy derivative, the amide pattern was especially characterized by the dominating olefinic piperideides. Greger and Werner (1990) compared the alkamides from the subterranean parts of different members of the *Achillea millefolium* group. They found that the European representatives (*A. millefolium*, *A. pannonica*, *A. collina*, *A. asplenifolia*, *A. setacea*) were predominated by deca-2 *E*,4 *E*,6*Z*-trienoic piperideide with some cytotypes accumulating two isomeric decatetraenoic piperideides and (+)-sesamin. The alkamide patterns of the Asian and North American members (*A. asiatica*, *A. lanulosa*) were characterized by a preponderance of decadienoic acid-derived isobutylamide and piperideide.

Thirteen compounds were identified in the essential oil: borneol, camphene, camphor, 1,8 cineole, α -pinene, *p*-cymene, furfuryl alcohol, isobutyl acetate, isovaleric acid, limonene, menthol, sabinene and terpinene-4-ol (Bejnarowicz and Smolenski 1968). Haggag et al. (1975) reported the following constituents in the essential oil: azulene, caryophyllene, eucalyptol, bor-

neol, bornyl acetate, α -pinene, β -pinene, limonene and α -thujone. The major components of the essential oil hydrodistilled from the stems, leaves and inflorescences were found to be β -thujone (8.3–21.7 %), camphor (8.6–11.7 %), 1, 8-cineole (7.7–15.2 %), β -pinene (3.8–7.8 %) and sabinene (5.7–8.9 %) (Hachey et al. 1990). More than 60 components have been identified, 40 of which were mainly oxygenated compounds. Several monoterpenes and sesquiterpenes were identified in the essential oil of wild *Achillea millefolium* complex in northern Greece, although the main component was ascaridole (47.2 %) (Chatzopoulou et al. 1992). Lesser amounts of 1, 8-cineole (10.5 %), *p*-cymene (7.4 %), α -terpinene (7.0 %) and camphor (8.1 %) were found. Bélanger and Dextraze (1993) reported the following as main components (range) in the essential oils of *A. millefolium* plants: chamazulene (51.3–1.16 %), germacrene D (54.7–5.6 %), β -thujone (35.1–0 %), α -thujone (20.7–0 %), α -phellandrene (17.4–0 %), sabinene (17.2–0.29 %), myrcene (14.7–0.10 %), β -pinene (9.74–0.2 %), β -caryophyllene (7.68–0.54 %), camphor (6.7–0.2 %), 1,8-cineole (6.45–0.26 %) *p*-cymene (1.73–0 %), bornyl acetate (3.88–0 %), camphene (2.68–0.11 %), limonene (3.11–0 %) and γ -terpinene (5.5–0.2 %).

The main volatile constituents found in *Achillea millefolium* growing wild in Greece were 1,8-cineole, camphor, borneol and lavandulol (Kokkalou et al. 1992). A comparison of the main volatile constituents currently found in *A. millefolium* oils revealed that great infraspecific variation occurred. One hundred twenty-three components were identified in the oil of aerial parts of *A. millefolium* from Kazakhstan representing 93.1 % of the oil (Suleimenov et al. 2001). Camphor (16 %), 1,8-cineole (8.7 %), borneol (6.2 %), β -eudesmol (6.1 %), α -terpineol (5.9 %), α -bisabolol (5.5 %) and terpinen-4-ol (3.1 %) were found as the major compounds.

Twenty components were identified in the essential oil of aerial parts of *A. millefolium* grown in Siberia (Smelcerovic et al. 2010). Major constituents were 1,8-cineole (28.8 %), camphor (11 %), borneol (5.9 %), β -pinene (5.4 %), caryophyllene oxide (3.3 %), β -caryophyllene (3.1 %),

α -elemol (3 %) and α -terpineol (2.9 %). Other components included α -pinene (2.5 %), terpinen-4-ol (2.3 %), camphene (0.7 %), sabinene (0.1 %), *p*-cymene (1.9 %), germacrene D (0.7 %), γ -terpinene (0.5 %), humulene (0.4 %), (Z)- β -farnesene (0.3 %), α -muurolene (0.2 %), cadina-3,9-diene (0.1 %) and hexahydrofarnesyl acetone (0.1 %). 1,4-dimethyl azulene, chamazulene, chamazulenecarboxylic acid and achillin were also found.

Trans-nerolidol (1–31.9 %), caryophyllene oxide (2.1–23 %), β -pinene (0.5–20.0 %), 1,8-cineole (0.5–11.9 %) were found to be the first predominant constituents in all 20 leaves and flower oils of white- and pink-flowering *A. millefolium* plants (Judzentiene and Mockute 2010). Other components found in all 20 samples included β -caryophyllene (1.7.7 %), α -pinene (0.1–6.3 %), sabinene (0.1–8.0 %), α -terpinene (tr – 0.6 %), borneol (tr – 8.4 %), terpinen-4-ol (tr – 2.8 %), α -terpineol (tr – 0.9 %), bornyl acetate (0.1–6.0 %), α -humulene (tr – 1.2 %), germacrene D (tr – 3.8 %) and (2Z,6E)-farnesyl acetate (tr – 3.5 %). Selin-11-en-4- α -ol (tr – 10.4 %) was also dominant and found in both leaf and flowers of ten pink- and seven white-flowered plants. 10-epi- γ -eudesmol was also dominant in 17 samples comprising 10 samples (tr – 12.2 %) in both flower and leaves of white cultivars and seven samples (0.8–5.8 %) in both flower and leaves of pink cultivars. Spathulenol was also dominant in 19 samples (tr – 10.2 %) in 10 white- and 9 pink-flowering plants. Other compounds found in 17–19 samples (leaf and flowers) included camphene (tr – 3.7 %), myrcene (tr – 1.1 %), *p*-cymene (tr – 2.4 %), γ -terpinene (0.1–1.4 %), terpinolene (tr – 2.3 %), camphor (tr – 6.7 %), *cis*-chrysanthanol (tr – 0.9 %), β -bourbonene (tr – 0.3 %), β -bisabolene (tr – 2.6 %), δ -cadinene (tr – 7.6 %), α/β -caryophylla—4(14), 8(15)-dien-5-ol (tr – 6.7 %) and (2Z,6E)-farnesol (tr – 1.7 %). Chamazulene was found in five samples (tr – 1.4 %) of the leaf and flower of the pink-flowered plants and one sample in the flower of white-flowered plant (2.7 %). 1-epi-cubenol was only found in white-flowered plants (nine out of ten samples, tr – 2.7 %). (2E, 6E)-farnesol was only found in

pink-flowered plants (tr – 1.9 %). Chrysanthenone and carvotanacetone were found only in the flower (7.2, 2.1 %) and leaf (7.6, 2.6 %) samples, respectively, of pink-flowered plant in the same one locality. Significant qualitative and quantitative variations were also found in the total content of monoterpenes (1.2–57.2 %) and sesquiterpenes (39.9–98.8 %).

Studies in Norway reported that the essential oil content of *Achillea millefolium* differed greatly between the vegetative stage (0.13 %) and the stage of full bloom (0.34 %) (Rohloff et al. 2000). Changes in the composition of yarrow essential oil were found to be related to maturation of the plant, with increasing amounts of monoterpenes in relation to the sesquiterpene. A clear trend was detected only for the monoterpene compounds with increasing levels of α -pinene and β -pinene and α -thujone and decreasing levels of sabinene, borneol and bornyl acetate. Previously reported as major compounds, chamazulene and germacrene D could be found only in insignificant amounts. Sesquiterpene compounds such as β -bisabolene, α -bisabolol and δ -cadinene were detected in substantial amounts by solid-phase microextraction (SPME) in contrast to the steam-distilled samples.

Twenty-one volatile constituents were isolated from the oil of Iranian *A. millefolium* (Afsharypuor and Asgary 1996). The oil possessed a high percentage (55.4 %) of sesquiterpenes. The major components of this fraction were α -bisabolol (22.9 %), spathulenol (12.4 %), *cis*-nerolidol (5.7 %), *cis*-carveol (5 %) and *trans,trans*-farnesol (4.0 %). Other components included phenol (3.9 %), *trans*-carveol (3.7 %), C₁₀H₁₈O₂ (3.5 %), *cis*-sabinol (2.5 %), *cis*- β -farnesene (2.7 %), α -patchoulene (2.2 %), 2-pentyl- 5-propylresorcinol (1.8 %), campherenone (1.7 %), C₁₅H₂₆O (1.7 %), bornyl acetate (1.3 %), β -himachalene (1.2 %), geranyl acetate (0.9 %), caryophyllene (0.9 %), 4-oxo-3,4-dihydro-2,3-diazaphenoxathin (0.9 %), 6,10,14-trimethyl pentadecan-2-one (0.8 %) and neryl acetate (0.7 %). The percentage of sesquiterpenes in the oil obtained from flowers and leaves of the plants grown in Portugal was much lower (up to 8.5 %) and was dominated by germacrene-D. The oil obtained from

Iranian *A. millefolium* ssp. *millefolium* possessed a high percentage of sesquiterpenes (55.4 %) in which α -bisabolol was the main compound, while no proazulene or 1,8-cineole was detected (Saeidnia et al. 2004). The major components of the oil were α -copaene (11.1 %) and (*E*)-nerolidol (8.8 %). The main constituents of *A. millefolium* essential oil from the Balkans (21 compounds) were β -pinene (32.63 %), β -caryophyllene (16.52 %), sabinene (11.48 %) and chamazulene (5.86 %), and these four compounds constituted 66.49 % of the oil (Boskovic et al. 2005). Other constituents included 1,8-cineole (4.57 %), caryophyllene oxide (3.74 %), bicyclogermacrene (2.70 %), α -pinene (2.52 %), bornyl acetate (2.42 %), germacrene D (2.12 %), α -humulene (2.12 %), α -phellandrene (0.76 %), α -terpinene (0.47 %), α -copaene (0.75 %), α -thujene (0.51 %), terpinolene (0.42 %), β -bourbonene (0.41 %), γ -terpinene (0.39 %), 4-terpineol (0.36 %), β -longipinene (0.20 %) and borneol (1.68 %). A total of 102 components were identified from the essential oil of *A. millefolium* plants from various European countries (Orav et al. 2006). The quantitatively most important components of yarrow were sabinene, β -pinene, 1,8-cineole, artemisia ketone, linalool, α -thujone, β -thujone, camphor, borneol, fenchyl acetate, bornyl acetate, (*E*)- β -caryophyllene, germacrene D, caryophyllene oxide, β -bisabolol, δ -cadinol, chamazulene and others.

Another study on the essential oil of *Achillea millefolium* subsp. *millefolium* in Iran identified 20 volatile components (Srabai and Meshkatsatsadati 2010). The predominant compounds were geraniol (33.43 %), neryl acetate (17.48 %), farnesol (7.61 %), benzyl benzoate (6.08 %), nerolidol (5.61 %), limonene (5.38 %) and linalool (3.15 %). Other constituents included neral (2.93 %), geranyl butyrate (2.67 %), α -pinene (2.53 %), 1,8-cineole (1.93 %), chrysanthenone (1.77 %), δ -elemene (1.00 %), β -pinene (0.68 %), α -terpineol (0.57 %), nerol oxide (0.54 %), *cis*-jasmone (0.47 %), sabinene (0.34 %), camphor (0.27 %) and geraniol (0.11 %). The Italian volatile extracts (SFE (supercritical extraction with CO₂) and essential oil) of aerial parts were predominantly composed by α -asarone (25.6–

33.3 %), and in the SFE extract and in the HD oil, respectively, β -bisabolene (27.3–16.6 %) and α -pinene (10.0–17.0 %), whereas the main components of the Portuguese extracts were *trans*-thujone (31.4–29.0 %), *trans*-chrysanthenyl acetate (19.8–15.8 %) and β -pinene (1.2–11.1 %) (Falconieri et al. 2011).

The populations *Achillea millefolium* from two different high-altitude Himalayan habitats (1,600 m, 2,850 m) proved to represent two different ecotypes: the 1,8-cineole type and the borneol type with appreciable differences in the contents of oils and mono- and sesquiterpenes (Agnihotri et al. 2005). The major components were characterized as β -pinene (10.6–17.7 %), 1,8-cineole (3.0–15.1 %), borneol (0.2–12.1 %), and β -caryophyllene (8.5–16.2 %). Thirty components were identified in the essential oil of *A. millefolium* cultivated under the tropical conditions of Delhi, India, comprising 93.43 % of the oil content (Nadim et al. 2011). The predominant constituents were sabinene (17.58 %), 1,8-cineole (13.04 %), borneol (12.41 %), bornyl acetate (7.98 %), α -pinene (6.28 %), β -pinene (6.26 %), terpinene-4-ol (6.17 %) and chamazulene (5.28 %). Other minor components included: β -caryophyllene (2.31 %), camphene (2.07 %), germacrene D (1.49 %), limonene (1.27 %), δ -terpinene (1.19 %), *p*-cymene (1.11 %), α -terpineol (1.04 %), methanol (1.03 %), α -thujone (1.00 %), δ -cadinene (0.94 %), α -cadinol (0.90 %), azulene (0.85 %), myrcene (0.81 %), thujanol (0.54 %), pentadecanoic acid (0.49 %), *trans*-carveol (0.44 %), myristic acid (0.23 %), dodecane (0.18 %), α -thujenal (0.16 %), α -copaene (0.13 %), myrtenol (0.13 %) and cyclohexene (0.12 %).

The terpenoid profile of homeopathic tincture prepared from fresh *A. millefolium* plant material comprised 1,8-cineole (18.28 %), α -pinene (11.96 %), germacrene D (11.62 %), phytol (11.20 %) and *trans*-caryophyllene (10.52 %), as dominant components (Lyakina 2002). Other components were sabinene (4.93 %), 1,4-terpineole (3.08 %), camphor (2.57 %), *trans*-sabinene hydrate (2.49 %), β -fenchol (2.49 %), lavandyl acetate (1.85 %), α -humulene (1.26 %) and 4-thujen-2- α -yl-acetate (1.07 %). In contrast, the terpenoid

profile of homeopathic tincture prepared from dried plant material comprised 1-limonene (29.92 %), sabinene (9.44 %), *trans*-caryophyllene (8.78 %) and phytol (7.59 %) as dominant components. The minor components were 1,8-cineole (5.27 %), lavandyl acetate (5.19 %), germacrene D (5.09 %), β -pinene (3.59 %), pseudocumene (3.20 %), episonarene (3.14 %), caryophyllene oxide (2.54 %), α -pinene (2.42 %), α -humulene (1.27 %), γ -selinene (0.94 %), α -longipinene (0.60 %) and camphene (0.24 %).

The terpenoid profile of homeopathic tincture prepared from fresh *A. millefolium* plant material comprised 1,8-cineole (18.28 %), α -pinene (11.96 %), germacrene D (11.62 %), phytol (11.20 %) and *trans*-caryophyllene (10.52 %), as dominant components (Lyakina 2002). Other components were sabinene (4.93 %), 1,4-terpineole (3.08 %), camphor (2.57 %), *trans*-sabinene hydrate (2.49 %), β -fenchol (2.49 %), lavandyl acetate (1.85 %), α -humulene (1.26 %) and 4-thujen-2- α -yl-acetate (1.07 %). In contrast, the terpenoid profile of homeopathic tincture prepared from dried plant material comprised of 1-limonene (29.92 %), sabinene (9.44 %), *trans*-caryophyllene (8.78 %) and phytol (7.59 %) as dominant components. The minor components were 1,8-cineole (5.27 %), lavandyl acetate (5.19 %), germacrene D (5.09 %), β -pinene (3.59 %), pseudocumene (3.20 %), episonarene (3.14 %), caryophyllene oxide (2.54 %), α -pinene (2.42 %), α -humulene (1.27 %), γ -selinene (0.94 %), α -longipinene (0.60 %) and camphene (0.24 %).

Leaf Phytochemicals

Rutin was isolated from the leaves (Neshta et al. 1972). 6-Hydroxyflavones, 6-hydroxyflavonols, and their methyl ethers predominated in the leaf exudates in various combinations in 78 collections of species forming the *Achillea millefolium* group (Valant-Vetschera and Wollenweber 1988). Leaves of field-grown plants accumulated higher concentrations (%w/w dw) than those of hydroponic grown plants in apigenin glycosides (0.25 versus 0.07 %) and total flavonoids (apigenin,

luteolin and apigenin glycosides) (0.26 versus 0.08 %) but lower amount of aglycone flavonoids of luteolin and apigenin (0.009 versus 0.012 %), respectively (Pedneault et al. 2002).

During the flowering period of *Achillea millefolium*, the leaf oil consisted mainly of monoterpenes (about 80 %); 1,8-cineole was the dominant component (18 %) followed by *trans*-sabinene hydrate (10 %) (Figueiredo et al. 1992a). The sesquiterpene fraction was dominated by germacrene-D (7 %). In the essential oil isolated from leaves collected during the vegetative phase, the monoterpene fraction was small (<3 %), whereas sesquiterpenes amounted to 92 %, germacrene-D being the major component (65 %) of the oil. Forty-two compounds were identified in the leaf oil of Cuban *A. millefolium*; caryophyllene oxide (20 %) was the major volatile constituent (Pino et al. 1998).

The major volatile aroma components of the leaf (area units divided by 100,000 per g dry matter) was α -pinene (96) and the rest were detected in very small to trace amounts: propanal, 2-methyl; butanal, 2-methyl; butanal, 3-methyl; pentanal; α -thujene; hexanal; β -pinene; sabinene; 1,8-cineole; and *p*-cymene (Dokhani et al. 2005). Total phenolics in the leaves were 32.7 mg/g dm and total tartaric esters were 11.7 mg/g dm.

Flower Phytochemicals

Three flavones, 5-hydroxy-3,6,7,4'-tetramethoxyflavone, artemetin and casticin, were isolated from the petroleum ether extract of the flowering heads of *Achillea millefolium* (Falk et al. 1975). From the ether extract of *Achillea millefolium* flowers, two guaianolides with a peroxide bridged cyclopentane ring and an α -methylene- γ -butyrolactone structure were isolated and the compounds were designated α -peroxyachifolid and β -peroxyisoachifolid. Three flavonoid aglycones, one triterpene, one germacranolide and five guaianolides were isolated and characterized from the dichloromethane extract of flower heads of a Hungarian taxon of the *Achillea millefolium* group (Glasl et al. 2002, 2003). Besides apigenin, luteolin and centaureidin, β -sitosterol, 3 β -hydroxy-

11 α ,13-dihydrocostunolide, desacetylmaticarin (= austricin, austrisin), leucodin (= desacetoxymatricarin, leucomisin), achillin, 8 α -angeloxyleucodin and 8 α -angeloxy-achillin were isolated. Eight phenolic compounds—chlorogenic acid and flavonoids—namely, vicenin-2, luteolin-3',7-di-*O*-glucoside, luteolin-7-*O*-glucoside, rutin, apigenin-7-*O*-glucoside, luteolin and apigenin, were identified in the extracts from yarrow (*Achillea millefolium*) flowers (Benetis et al. 2008). The total amount of the identified phenolics in yarrow flowers from different populations varied from 13.290 to 27.947 mg/g.

Achillinin A (2 β ,3 β -epoxy-1 α ,4 β ,10 α -trihydroxyguai-11(13)-en-12,6 α -olide), a new guaianolide, was isolated from the flower (Li et al. 2011). Ten 1,10-secoguaianolides were isolated from the flowers of *Achillea millefolium* (Li et al. 2012a). Three of them (millifolides A–C) including two dimeric sesquiterpenoids exhibit new skeletons. Seco-tanapartholide A was found to be cytotoxic. Sesquiterpene dimers, Achillin B and C, were isolated from the flowers (Li et al. 2012b).

Inflorescences of *A. millefolium* grown in the Sibiu district, Romania was found to contain between 0.18 and 0.59 % (mean 0.34 %) volatile oil (Popescu and Pop-Hakkel 1980). The azulenes from the oil varied between 1.5 and 19.6 % (mean 7.04 %). The following components were identified in the volatile oil: caryophyllene, chamazulene, linalyl, acetate, bornyl acetate, limonen, 1,8-cineole, linalol, borneol, terpineol and geraniol. Two of the samples showed a different chemical composition, one of them lacking 1,8-cineole, the other bornyl acetate. During the flowering period of *Achillea millefolium*, the flower oil consisted mainly of monoterpenes (about 80 %); 1,8-cineole was the dominant component followed secondly by sabinene (15 %) (Figueiredo et al. 1992a). The sesquiterpene fraction was dominated by germacrene-D (0.7 %). The monoterpene fraction was dominant in the oils (ca 80 %) from two populations of *Achillea millefolium* L. ssp. *millefolium*, growing in the Botanical Garden of Lisbon (BGL) and in the Caneco Garden of Almada (CGA) (Figueiredo

et al. 1992b). The main components differed: sabinene and 1,8-cineole were dominant in the BGL oils, while camphor, 1,8-cineole and β -pinene were the main constituents of CGA oils. Germacrene-D was the major component of the sesquiterpene fraction of all the oils analyzed. Chamazulene was only detected in the oils from the flower heads collected in CGA; its amount decreases through flower-head development.

The major volatile aroma flower components of *A. millefolium* grown in Iran (expressed as area units divided by 100,000 per g dry matter) were α -pinene (1,350), 1,8-cineole (950), β -pinene (674), sabinene (400), β -pinene (381), γ -terpinene (325), *trans*-caryophyllene (328), α -terpinene (205) and DL-limonene (200) (Dokhani et al. 2005). Other minor components included propanal, 2-methyl; butanal, 2-methyl; butanal, 3-methyl; pentanal; α -thujene; α -fenchene; camphene; hexanal; α -phellandrene; β -phellandrene; 3,7-dimethyl-1,3,6-octatriene; *p*-cymene; α -terpinoline; allocimene, camphor; *trans*-caryophyllene; α -humulene, cadinene isomer; (*E*)-farnesene; δ -cadinene; γ -cadinene; and an unknown terpinene. Total phenolics in the flowers was 35.7 mg/g dm and total tartaric esters were 12.9 mg/g dm.

Achillea millefolium L. sensu lato, is a cytogenetically, morphologically and chemically polymorphic aggregate (Benedek et al. 2007a). Besides possessing sesquiterpenes that have chemotaxonomic relevance and mediate the anti-phlogistic activity, the plant contains phenolic compounds such as dicaffeoylquinic acids and flavonoids causing choleretic and spasmolytic effects. The investigated species displayed differences in the quantitative and qualitative composition of phenolic acids and flavonoids. The following flavonoids were found in the flower heads of *Achillea* species belonging to the *A. millefolium* group (Trendafilova et al. 2007): *A. collina*, artemetin (1.6 mg), casticin (1.3 mg), centaureidin (7.4 mg), quercetagenin 6,7,3',4'-tetramethyl ether (1.0 mg), 6-hydroxykaempferol 3,6,7,4'-tetramethyl ether (1.0 mg), santin (4.0 mg), pectolinarigenin (1.5 mg) and diosmetin (1.5 mg); *A. asplenifolia*, artemetin (6.0 mg),

casticin (1.7 mg), centaureidin (1.4 mg), quercetagenin 6,7,3',4'-tetramethyl ether (1.1 mg), 6-hydroxykaempferol 3,6,7,4'-tetramethyl ether (1.0 mg) and apigenin (3.0 mg); and *A. distans*, centaureidin (2.0 mg), santin (1.5 mg), pectolinarinigenin (1.5 mg), ermanin (1.0 mg), acetin (1.3 mg), mixture of diosmetin and chrysoeriol (1.5 mg) and luteolin (1.5 mg).

Root Phytochemicals

Roots of hydroponic grown plants accumulated higher concentrations (%w/w dw) than those of field-grown plants in apigenin glycosides (1.91 versus 0.49 %) and total flavonoids (apigenin, luteolin and apigenin glycosides) (1.92 versus 0.51 %) but lower amount of aglycone flavonoids of luteolin and apigenin (0.007 versus 0.014 %), respectively (Pedneault et al. 2002).

The various pharmacological activities of *Achillea millefolium* species may be due to the presence of a broad range of secondary active metabolites in the essential oils and extracts of various plant parts such as flavonoids, phenolic acids and dicaffeoylquinic acids, coumarins, proazulenes, monoterpenes, sesquiterpenes, sesquiterpene lactones, diterpenes, triterpenes and sterols (Chandler et al. 1982b; Nemeth and Bernath 2008; Saeidnia et al. 2011). The largest number of data accumulated for antioxidant and antiinflammatory effects, and there are positive results on the analgesic, antiulcer, choleric, hepatoprotective and wound-healing activities (Nemeth and Bernath 2008). Interesting findings have highlighted antihypertensive, antidiabetic, antitumor and antispermatic activities. Recent findings have confirmed several traditional uses. However, human clinical studies are still warranted.

Antioxidant Activity

Achillea millefolium essential oil strongly reduced the diphenylpicrylhydrazyl radical ($IC_{50}=1.56 \mu\text{g/ml}$) and exhibited hydroxyl radi-

cal scavenging effect in the Fe^{3+} -EDTA- H_2O_2 deoxyribose system ($IC_{50}=2.7 \mu\text{g/ml}$) (Candan et al. 2003). It also inhibited the nonenzymatic lipid peroxidation of rat liver homogenate ($IC_{50}=13.5 \mu\text{g/ml}$). Eucalyptol, camphor, α -terpineol, β -pinene and borneol were the principal components comprising 60.7 % of the oil. The polar phase of the methanol extract also showed antioxidant activity. Antioxidant activity in terms of TEAC (μM trolox/100 g DW) of *A. millefolium* herb reported was 11.2 μM for ABTS, 200 μM for DPPH and 191 μM for FRAP (ferric reducing antioxidant power) assays (Wojdyło et al. 2007). Total phenolic content was 9.55 mg GAE/100 g DW.

Studies showed that all plant infusions of 15 *Achillea* species were effective on antioxidant enzyme systems of erythrocytes and leucocytes when compared with the hydrogen peroxide-induced group (Konyalioglu and Karamenderes 2005). Among the plant infusions, *Achillea millefolium* subsp. *pannonica* showed highest activity on superoxide dismutase. The methanol and aqueous extracts of *Achillea millefolium* exhibited DPPH radical scavenging activity with 75 and 50.8 % inhibition, respectively (Eghdami and Sadeghi 2010). The extracts contained 123.9 and 48.4 mg GAL/g total phenolic content and 41.2 and 13.15 mg QE/g flavonoids, respectively. The methanol extract of *A. millefolium* and its flavonol glycosides and chlorogenic acids exhibited significant antioxidant properties as measured by free-radical scavenging activity against 2,2-diphenyl-picrylhydrazyl, total antioxidant capacity (based on the reduction of Cu^{2+} to Cu^+), and ability to inhibit lipid peroxidation as measured by TBARS assay (Vitalini et al. 2011). The results from the TBARS assay showed that among the compounds isolated, only luteolin 7-*O*-glucoside and apigenin 7-*O*-glucoside displayed an activity somewhat comparable to that of chlorogenic acid, even at the lowest concentration tested (1 μM); all the other phenolic compounds were able to inhibit the TBARS formation only at the highest concentration tested (10 μM). Total antioxidant capacity (%) (DPPH

scavenging activity) of yarrow aerial plant parts was 8.29 % and contribution from the main caffeoyl derivatives was as follows: chlorogenic acid 10.01 %, 3,5-DCQA (dicafeoylquinic acid) 33.17 %, 1,5-DCQA 13.63 %, 4,5-DCQA 4.99 %, total caffeoyl derivatives 61.80 % (Fraisie et al. 2011).

An on-line HPLC-DPPH assay showed that *Achillea millefolium* possessed significant anti-radical activity attributable to the presence of active phenolic compounds (Trumbeckaite et al. 2011). Its phenolic compounds had no effect on mitochondrial State 3 respiration rate. The extract at concentrations that had no effect on the State 3 respiration rate significantly decreased H_2O_2 production in mitochondria.

Vahid et al. (2012) conducted a randomized controlled trial involving 31 chronic kidney disease patients; 16 were administered 1.5 g of powdered *A. millefolium* flower 3 days a week for 2 months and 15 received placebo for the same period. They found that countercurrent to the placebo group, plasma nitric oxide metabolites, were marginally decreased after *A. millefolium* administration in chronic kidney disease patients. Nitric oxide-scavenging properties had been reported with some *Achillea* species.

Anticancer Activity

Three sesquiterpenoids, achimillic acids A, B and C, were found to be active against mouse P-388 leukemia cells in vivo (Tozyo et al. 1994). The flavonoid casticin, derived from *Achillea millefolium*, was found to have antitumor activity (Haïdara et al. 2006). Casticin caused cell growth arrest in G2/M and inapoptotic death. As a tubulin-binding agent (TBA), Casticin induced p21, which in turn inhibited Cdk1. Further, casticin appeared to downregulate cyclin A. Following casticin exposure, Bcl-2 depletion occurred in cancer cells, and a sub-G1 accumulation occurred in the cell cycle. A number of features suggested that casticin could be important in cancer therapy as Pgp-overexpressing cells were not resistant to casticin, and its cell killing effect was observed even in p53 mutant or null cell lines.

The chloroform-soluble extract of aerial parts of the *Achillea millefolium* aggregate exerted high tumour cell proliferation inhibitory activities on cervical cancer HeLa and breast cancer MCF-7 cells and a moderate effect on human epithelial carcinoma A431 cells (Csupor-Löffler et al. 2009). In the antiproliferative assay centaureidin was the most effective constituent of the aerial parts of yarrow, exhibiting high cell growth inhibitory activities especially on HeLa (IC_{50} 0.0819 μ m) and breast cancer MCF-7 (IC_{50} 0.1250 μ m) cells. Casticin and paulitin were also highly effective against all three tumour cell lines (IC_{50} 1.286–4.76 μ m), while apigenin, luteolin and isopaulitin proved to be moderately active (IC_{50} 6.95–32.88 μ m). Artemetin, psilostachyin C, desacetylmaticarin and sintonin did not display antiproliferative effects against these cell lines.

Achillinin A isolated from the flower exhibited potential antiproliferative activity to adenocarcinomic human alveolar basal epithelial A549, human lung adenocarcinoma RERF-LC-kj and human lung carcinoma QG-90 cells with 50 % inhibitory concentration (IC_{50}) values of 5.8, 10 and 0.31 μ M, respectively (Li et al. 2011). Secotanapartholide A isolated from the flower, exhibited moderate cell growth inhibitory activity in vitro against the human cancer cell line MCF7 (IC_{50} =5.51 μ m) (Li et al. 2012a).

Antiinflammatory Activity

A water-soluble protein–carbohydrate complex isolated from the aqueous extract of *Achillea millefolium* flowers, at a dose of 40 mg/kg, exerted antiinflammatory activity as measured by the mouse paw edema test (Goldberg et al. 1969).

The crude plant extract of *A. millefolium* and its flavonoid fraction inhibited human neutrophil elastase (HNE) with IC_{50} values of approximately 20 μ g/ml, whereas the dicafeoylquinic acids fraction was less active (IC_{50} =72 μ g/ml) (Benedek et al. 2007b). The inhibitory activity on matrix metalloproteinases (MMP-2 and -9) was observed at IC_{50} values from 600 to 800 μ g/ml, whereas the DCQA fraction showed stronger effects than the

flavonoid fraction and the extract. The scientists concluded that the in-vitro antiphlogistic activity of *Achillea* was at least partly mediated by inhibition of HNE and MMP-2 and MMP-9.

Aqueous extract from *Menyanthes trifoliata* induced a suppressive phenotype of dendritic cells that had reduced capacity to induce Th1 and Th17 stimulation of allogeneic CD4(+) T cells, whereas aqueous extract from *Achillea millefolium* reduced the capacity of dendritic cells to induce a Th17 response (Jonsdottir et al. 2011). Both Th1 and Th17 cells had been implicated in the pathogenesis of inflammatory bowel disease and experimental colitis.

Hepatoprotective Activity

Pretreatment of mice with *Achillea millefolium* crude extract (150–600 mg/kg) significantly prevented D-galactosamine (D-GalN)- and lipopolysaccharide (LPS)-induced rise in plasma alanine aminotransferase (ALT) and aspartate aminotransferase (AST) levels (Yaesh et al. 2006). The hepatoprotective effect of the extract was further verified by histopathology of the liver, which showed improved architecture, absence of parenchymal congestion, decreased cellular swelling and apoptotic cells, compared with (D-GalN) and LPS groups of animals. In isolated rabbit jejunum preparations, the extract caused a concentration-dependent (0.3–10 mg/ml) relaxation of both spontaneous and K⁺-induced contractions as well as shifting the Ca²⁺ concentration-response curves (CRCs) to the right, similar to that caused by verapamil. These results indicated that the crude extract of *Achillea millefolium* exhibited a hepatoprotective effect, which may be partly attributed to its observed calcium channel blocking activity.

Spasmolytic Activity

The flavonoid fraction of *Achillea millefolium* exhibited spasmolytic activity on isolated terminal guinea pig ilea (Lemmens-Gruber et al. 2006). The aglycones quercetin, luteolin and apigenin

exhibited the highest antispasmodic activities with IC₅₀ values of 7.8, 9.8 and 12.5 µmol/l, respectively. Rutin and the flavonoid metabolites homoprotocatechuic acid and homovanillic acid showed no significant effects on contractility of the terminal ilea. They concluded that in tea prepared from yarrow, the concentration of the flavonoids was high enough to exert a spasmolytic effect in the gut, which was mainly caused by blockade of the calcium inward current, but additionally also by mediator antagonistic effects. In another study, *Achillea millefolium* hydroalcoholic extract inhibited electrical induced contractions of the isolated guinea pig ileum in a dose-dependent manner with EC₅₀ value of 1.5 mg/ml (Babaei et al. 2007).

Choleretic Activity

A fraction of a 20 % methanol yarrow (*Achillea millefolium*) extract enriched in 3,4-, 3,5- and 4,5-DCCA dicaffeoylquinic acids (DCCAs) and luteolin-7-*O*-β-D-glucuronide was found to have choleretic effect in isolated perfused rat liver (IPRL) (Benedek et al. 2006). The fraction caused a dose-dependent increase in bile flow (23–44–47 %). Choleresis was two- to three-fold higher than that of cynarin, the main choleretic compound of *Cynara scolymus*, used as internal standard. The combined effect of DCCAs and luteolin-7-*O*-β-D-glucuronide stimulated bile flow more effectively than the single compound cynarin. Due to their polar structure, these compounds are quantitatively extracted into teas and tinctures.

Estrogenic Activity

A crude extract of the aerial parts of *A. millefolium* exhibited estrogenic activity in-vitro in recombinant MCF-7 cells (Innocenti et al. 2007). After fractionation of the crude extract, nine compounds were isolated and characterized: dihydrodehydrodiconiferyl alcohol 9-*O*-β-D-glucopyranoside, a glycosyl-neolignan; six flavone derivatives, apigenin, apigenin-7-*O*-β-D-glucopyranoside, luteolin, luteolin-7-*O*-β-D-glucopyranoside, luteolin-

4'-*O*- β -D-glucopyranoside, rutin; and two caffeic acid derivatives, 3,5-dicaffeoylquinic acid and chlorogenic acid. Apigenin and luteolin were the most important estrogenic compounds among those tested, for their ability to activate alpha or beta oestrogen receptors (ERalpha, ERbeta) using transiently transfected cells.

Antilulcerogenic Activity

Oral administration of rats with a hydroalcoholic extract of *Achillea millefolium* (30, 100 and 300 mg/kg) inhibited ethanol-induced gastric lesions by 35, 56 and 81 %, respectively (Potrich et al. 2010). Oral treatment with the extract (1 and 10 mg/kg) reduced the chronic gastric ulcers induced by acetic acid by 43 and 65 %, respectively, and promoted significant regeneration of the gastric mucosa after ulcer induction denoting increased cell proliferation, which was confirmed by PCNA (proliferating cell nuclear antigen) immunohistochemistry. The extract prevented the reduction of glutathione levels and superoxide dismutase activity after acetic acid-induced gastric lesions. The results suggested that the antioxidant properties of the hydroalcoholic extract may contribute to its gastroprotective activity.

Aqueous extract of *A. millefolium* aerial parts was found to be effective in protecting the gastric mucosa against acute gastric lesions induced by ethanol and indomethacin and in healing chronic gastric lesions induced by acetic acid with (ED₅₀ = 32 mg/kg, p.o.) (Cavalcanti et al. 2006). Safety study showed slight changes in liver weight, cholesterol, HDL-cholesterol and glucose observed in male and female Wistar rats that were not correlated with dose or time of exposure of the animals. The results showed the antiulcer potential of *Achillea millefolium* extract that was accompanied by signs of relevant toxicity even at very long chronic exposure.

Immunomodulatory Activity

Achillea millefolium essential oil and 70 % crude ethanol leaf extract modulated the activation peritoneal macrophages cells from Swiss mice by

weakly increasing nitric oxide (NO), at concentrations of 20, 10 and 5 mg/ml, compared to LPS (lipopolysaccharide-potent stimulator of NO production) (Lopes et al. 2003). They also reported *A. millefolium* essential oil was able to stimulate peritoneal macrophages to produce H₂O₂ and TNF- α without causing an overproduction of these compounds in peritoneal macrophages cells from Swiss mice, suggesting that the essential oil could modulate macrophages activation (Lopes et al. 2005).

Three glycosylated phenolic compounds, luteolin 7-*O*-glucoside, apigenin 7-*O*-glucoside and caffeic acid glucoside, were isolated from the methanol extract of aerial parts of *Achillea millefolium* (Yassa et al. 2007), and the immunological properties of different fractions of plant extract were studied on humoral immune system of BALB/c mice using microhaemagglutination test. Only two fractions at 125 and 61.5 mg/kg showed a significant decrease in the anti-SRBC (sheep red blood cell) titer of mice. The immunological properties of the fractions may be attributed to glycosylated derivatives of caffeic acid.

Spasmogenic Activity

A water extract of dried flower heads of *A. millefolium* exerted a direct spasmogenic effect on mouse and human gastric antrum (Borrelli et al. 2012). Among its constituents, choline, but not the flavonoids rutin and apigenin, mimicked the spasmogenic action. The authors concluded that the prokinetic effect of *A. millefolium* extract observed in vivo could provide the pharmacological basis underlying its traditional use in the treatment of dyspepsia.

Vasoprotective Activity

Achillea millefolium extract was found to enhance primary rat vascular smooth muscle cells by partly acting through oestrogen receptors and impairing NF- κ B signalling in human umbilical vein endothelial cells (HUVECs) (Dall'Acqua et al. 2011). The results suggested that the extract

may have vasoprotective effect against vascular inflammation.

Antiplasmodial Activity

Among the phenolic compounds isolated from *A. millefolium* methanol extract, apigenin 7-*O*-glucoside and luteolin 7-*O*-glucoside were the most active against both strains of *Plasmodium falciparum* (Vitalini et al. 2011). The chlorogenic acids were completely inactive.

Hemostatic Activity

A glycoalkaloid, achilleine, isolated from the leaves was found to reduce clotting time in rabbits by 37 % (Miller and lee 1954).

Antinociceptive Activity

The hydroalcohol extract of *Achillea millefolium* (500 and 1,000 mg/kg) significantly inhibited abdominal contortions by 65 and 23 %, respectively, whereas *Artemisia vulgaris* (500 and 1,000 mg/kg) inhibited them by 48 and 59 %, respectively (Pires et al. 2009). None of the extracts produced differences in the intestinal transit in mice, nor in the response time in the hot plate or in the immediate or late responses in the formalin test. Both hydroalcohol extracts showed the same flavonoid glycoside as a principal constituent, which was identified as rutin. A high content of caffeic acid derivatives were also found in both extracts.

Hypotensive and Vaso- and Bronchodilatory Activities

The oral administration of *A. millefolium* hydro-ethanol extract (100–300 mg/kg), dichloromethane fractions (20 and 10–30 mg/kg), but not ethyl acetate fraction (10 mg/kg) and butanolic fraction (50 mg/kg) fractions significantly reduced the mean arterial pressure (MAP) of normotensive rats (De Souza et al. 2011). The dichloromethane

fractions were found to contain high amounts of artemetin which when administered by either oral (1.5 mg/kg) or intravenous (0.15–1.5 mg/kg) to rats was able to dose-dependently reduce the MAP. Intravenous injection of artemetin (0.75 mg/kg) significantly reduced the hypertensive response to angiotensin I while increasing the average length of bradykinin-induced hypotension. Artemetin (1.5 mg/kg, p.o.) was also able to reduce plasma (about 37 %) and vascular (up to 63 %) angiotensin-converting enzyme activity in-vitro, compared to control group.

The crude extract of *Achillea millefolium* caused a dose-dependent (1–100 mg/kg) fall in arterial blood pressure of rats under anaesthesia (Khan and Gilani 2011). In spontaneously beating guinea pig atrial tissues, the extract exerted negative inotropic and chronotropic effects. In isolated rabbit aortic rings, the extract (0.3–10 mg/ml) relaxed phenylephrine and high K⁺-induced contractions. In guinea pig tracheal strips, the extract suppressed carbachol and K⁺-induced contractions. The results indicated that *A. millefolium* extract exhibited hypotensive, cardiovascular inhibitory and bronchodilatory effects and thus elucidated its use in hyperactive cardiovascular and airway disorders, such as hypertension and asthma.

Skin-Rejuvenating Activity

Studies showed that *Achillea millefolium* extract improved expression profile of various epidermal differentiation markers: cytokeratin 10, transglutaminase-1 and filaggrin in cultured skin biopsies as well as increased epidermal thickness (Pain et al. 2011). In-vivo, a 2-month treatment with 2 % *A. millefolium* extract significantly improved the appearance of wrinkles and pores compared with placebo. Results were also directionally better than those of glycolic acid that was chosen as reference resurfacing molecule.

Anxiolytic Activity

Studies in mice showed that *Achillea millefolium* exerted anxiolytic-like effects in the

elevated plus-maze and marble-burying test after acute and chronic (25 days) oral administration at doses that did not alter locomotor activity (Baretta et al. 2012). This behavioral profile was similar to diazepam. The effects of *Achillea millefolium* in the elevated plus-maze were not altered by picrotoxin pretreatment but were partially blocked by flumazenil. Further, *Achillea millefolium* did not induce any changes in [(3)H]-flunitrazepam binding to the benzodiazepine (BDZ) site on the GABA(A) receptor indicating that the anxiolytic-like effects were likely not mediated by GABA(A)/BDZ neurotransmission.

Antimicrobial Activity

Achillea millefolium essential oil showed antimicrobial activity against *Streptococcus pneumoniae*, *Clostridium perfringens*, *Candida albicans*, *Mycobacterium smegmatis*, *Acinetobacter lwoffii* and *Candida krusei*, while water-insoluble parts of the methanol extracts exhibited slight or no activity (Candan et al. 2003). *Achillea millefolium* oils exhibited the antifungal activity against *Candida albicans*, *C. tropicalis*, *C. krusei*, *C. guilliermondii*, *C. parapsilosis*, *Cryptococcus neoformans*, *Aspergillus niger*, *A. fumigatus*, *A. flavus* and dermatophytes *Trichophyton rubrum*, *T. mentagrophytes*, *T. mentagrophytes* var. *interdigitale*, *T. verrucosum*, *Microsporum canis*, *M. gypseum* and *Epidermophyton floccosum* (Falconieri et al. 2011). The oils showed the highest activity against dermatophyte strains, with MIC values ranging from 0.32 to 1.25 µl/ml.

Cyclophosphamide Toxicity Amelioration Activity

Studies showed that *Achillea millefolium* inflorescence aqueous extract may be partially protective against cyclophosphamide-induced testicular toxicity in male Wistar rats (Jalali et al. 2012). Cyclophosphamide-treated rats showed significant decreases in the body, testes and epididymides weights as well as many his-

tological alterations. Stereological parameters, spermatogenic activities and testicular antioxidant capacity along with epididymal sperm count and serum testosterone concentration were also significantly decreased by cyclophosphamide. Co-treatment with *A. millefolium* extract caused a partial recovery in above-mentioned parameters.

Anticonflict Behaviour Activity

Molina-Hernandez et al. (2004) found that anticonflict-like behaviour actions of aqueous extract of *Achillea millefolium* flowers in female Wistar rats may vary according to the oestrous cycle phase. Doses of 8.0, 10.0, or 12.0 mg/kg of the extract reduced conflict behaviour during late proestrus. Conversely, during diestrus, only the dose of 12.0 mg/kg reduced conflict behaviour. During late proestrus, control rats displayed reduced conflict behaviour compared with diestrus. Diazepam (2.0 mg/kg; i.p.) reduced conflict behaviour both during late proestrus or diestrus.

Anthelmintic Activity

In-vitro studies revealed significant anthelmintic effects of aqueous extracts and ethanol extracts on live *Haemonchus contortus* worms as evident from their paralysis and/or death at 8 hours post-exposure (Tariq et al. 2008). Aqueous extracts of *A. millefolium* resulted in a mean worm motility inhibition of 94.44 %, while ethanol extracts resulted in mean worm motility inhibition of 88.88 %. The mean mortality index of aqueous extracts was 0.95 while for ethanol extracts it was 0.9. The lethal concentration 50 was 0.05 mg/ml for aqueous extracts and 0.11 mg/ml for ethanol extracts. The in-vivo anthelmintic activity of aqueous and ethanol extracts of *A. millefolium* demonstrated a maximum (88.40 %) nematode egg count reduction in sheep treated with aqueous extracts at 2 g/kg body weight on day 15 after treatment and 76.53 % reduction in faecal egg count for the ethanol extract at the same concentration.

Insecticidal Activity

A methanol extract of *Achillea millefolium* exhibited activity against 24-h-old larvae of *Aedes triseriatus* (Lalonde et al. 1980). The active principle was found to be the antilarval *N*-(2-methylpropyl)-(*E,E*)-2,4-decadienamide. Isolated and synthesized amides at 5 ppm resulted in 98 and 100 % mortality of 24-h-old *A. triseriatus* larvae. The *N*-(2-methylpropyl)-amides of decanoic and (*E*)-2-decenoic acids showed the same order of antilarval activity as *N*-(2-methylpropyl)-(*E,E*)-2,4-decadienamide, but *N*-(2-methylpropyl)sorbamide was inactive.

An ethanol extract of *Achillea millefolium* showed repellent activity against the mosquito, *Aedes aegypti* (Tunón et al. 1994). Of 35 compounds isolated from fractions of the extract, the most active were the nitrogen-containing compound stachydrine; the carboxylic acids, caffeic, chlorogenic and salicylic acids; and the phenolic compound pyrocatechol. They showed a distance and contact-repelling activity similar to the well-known repellent *N,N*-diethyl-m-toluamide (DEET) at about the same concentrations. Some further substances with lower activity were characterized for the first time in *A. millefolium*, i.e., adenine, ferulic and mandelic acid and the methyl esters of caprylic acid, linolenic acid and undecylenic acid.

Antileishmanial Activity

Studies showed that *Achillea millefolium* hydroalcoholic extract was effective for treatment of cutaneous leishmaniasis in mice (Nilforoushzadeh et al. 2008). Leishmaniasis is a parasitic disease transmitted by sand flies. The extract was more effective than glucan-time. Mean of ulcer size reduction was 43.29 %. The essential oil from the leaves and flowers of *Achillea millefolium* was found to have antileishmanial activity in vitro (Santos et al. 2010). The median inhibitory concentration (IC₅₀) against *Leishmania amazonensis* promastigotes was 7.8 µg/ml, whereas the survival of amastigotes of this pathogen, within

peritoneal murine macrophages, was halved by treatment with the oil at 6.5 µg/ml. The mean value for the median cytotoxic concentration of the oil, measured against adherent (uninfected) J774G8 macrophages, was 72.0 µg/ml (i.e., 9.2 and 11.0 times higher, respectively, than the IC₅₀ against the promastigotes and intracellular amastigotes). Scanning and transmission microscopy studies showed that the oil caused alterations in shape, size and ultrastructural changes.

Trypanocidal activity

Treatment with *A. millefolium* essential oil inhibited the growth of *Trypanosoma cruzi* epimastigote and bloodstream trypomastigote forms (Santoro et al. 2007) but was less effective than clove oil.

Antifertility (Antispermatogetic) Activity

The ethanol extract (200 mg/kg/day, intraperitoneally, for 20 days) and a hydroalcoholic extract (300 mg/kg/day, orally, for 30 days) of *Achillea millefolium* flowers exerted antispermatogetic effect in Swiss mice (Montanari et al. 1998). The alterations observed were exfoliation of immature germ cells, germ cell necrosis and seminiferous tubule vacuolization. Animals treated with the extracts had an increased number of metaphases in the germ epithelium that might be due to cytotoxic substances or substances stimulating cell proliferation. Studies showed that administration *A. millefolium* extract at a dose of 800 mg/kg by intraperitoneal (IP) injection or through gavage to male Wistar rats for 22 days exerted temporary antispermatogetic effect on treated rats (Takzare et al. 2011). IP resulted in thickened seminiferous tubules on basal membrane, decrease in cell accumulation in seminiferous tubule, severe disarrangement, degenerative cells and severe decrease in sperm count. Oral administration caused thickening of basal membrane and cell disarrangement.

Toxicity/Genotoxicity Studies

A. millefolium, 0.35 and 3.5 mg/ml, did not cause statistically significant inhibition of cellular division in the onion root-tip cells (Teixeira et al. 2003). No statistically significant alterations were found, as compared to untreated controls, in either the cell cycle or the number of chromosome alterations, after treatments with *A. millefolium*, in rat cells or in cultured human lymphocytes. These results regarding the cytotoxicity and mutagenicity of *A. millefolium* provide valuable information about the safety of using them as therapeutic agents. Reproductive evaluation of aqueous crude extract of *Achillea millefolium* administered daily (0.3, 0.6 and 1.2 g/kg/day) during 90 days to male Wistar rats revealed no clinical signs of toxicity (in reproductive organ weights, sperm and spermatid numbers) over the treatment period, and body weight gain was similar in all groups (Dalsenter et al. 2004). A significant increase in the percentage of abnormal sperm in the group treated with the highest dose of yarrow extract was detected with no other important changes in the other reproductive endpoints. Additionally, a 3-day treatment of immature female rats with yarrow extract did not show any uterotrophic effects. Animal studies had shown yarrow to be generally safe and well tolerated but more human clinical studies were warranted (Applequist and Moerman 2011). The claim that yarrow had been shown to be specifically contraindicated during pregnancy was based on a single low-quality rat study, the results of which were incorrectly interpreted.

A. millefolium essential oil exhibited genotoxicity in a heterozygous diploid strain of *Aspergillus nidulans*, with green conidia (de Sant'anna et al. 2009). A statistically significant increasing number of yellow and white mitotic recombinants, per colony, of the diploid strain was reported after oil treatment with 0.19 and 0.25 µl/ml concentrations. The genotoxicity of the oil was associated with the induction of mitotic nondisjunction or crossing over.

The Final report on the Safety Assessment of Yarrow (*Achillea millefolium*) concluded that available published data were insufficient to support the safety of yarrow extract for use in cos-

metic products (Anonymous 2001b). The following data were still required: (1) ultraviolet (UV) absorption data, if absorption occurs in the UVA or UVB range, photosensitization data are needed; (2) gross pathology and histopathology in skin and other major organ systems associated with repeated exposures; (3) reproductive and developmental toxicity data; (4) two genotoxicity studies, one using a mammalian system, if positive, a 2-year dermal carcinogenicity assay performed using National Toxicology Program (NTP) methods may be needed; and (5) clinical sensitization testing at maximum concentration of use.

Allergy Problems

Alpha-peroxyachifolid, a soluble component of yarrow was found to cause allergic contact dermatitis (Rücker et al. 1991). Alpha-peroxyachifolid was found to be a strong sensitizer in guinea pig sensitization experiments (Hausen et al. 1991). Other minor sesquiterpene lactones also contribute marginally to the sensitizing activity, while other known yarrow constituents like dehydromatricaria ester and pontica epoxide appeared to play no role.

Traditional Medicinal Uses

Yarrow (*Achillea millefolium* L.) is one of the most widely used plants in folk medicine in the world since antiquity. Yarrow is regarded as antiseptic, antispasmodic, mildly aromatic, astringent, carminative, cholagogue, diaphoretic, digestive, emmenagogue, odontalgic, stimulant, bitter tonic, vasodilator and vulnerary (Grieve 1971; Bown 1995; Chopra et al. 1986). It has been used for treating wounds, inflammation, pain, liver disorders, gastritis disorders, amenorrhea, bowels, bleeding, hypertension, menstrual pains, dyspepsia, eczema, gum ailments, influenza, fevers and colds, catarrh, chicken pox, smallpox, measles, cystitis, diabetes, kidney diseases, menorrhagia, toothache, thrombosis, ulcers, varicose veins, lung haemorrhage, arthritis and poor vision (Grieve 1971; Chandler et al. 1982a, b; Duke and Ayensu

1985; Chopra et al. 1986; Bown 1995; Chevallier 1996). Yarrow is traditionally used against inflammatory and spasmodic gastrointestinal complaints, digestive problems, respiratory infections, hepatobiliary disorders, blood purification, as an appetite enhancing drug, against skin inflammations and for wound healing due to its antiphlogistic, choleric and spasmolytic properties and, secondarily, among other uses, for liver disease and as a mild sedative (Benedek and Kopp 2007; Benedek et al. 2008; Applequist and Moerman 2011). The main pharmacologically active principles were shown to be the essential oil (antimicrobial), proazulenes and other sesquiterpene lactones (antiphlogistic), dicaffeoylquinic acids (choleric) and flavonoids (antispasmodic) (Benedek et al. 2008). Yarrow is used in folk medicine as an emmenagogue (Innocenti et al. 2007).

A. millefolium is employed for the treatment of many different ailments in Iran (Kokkini et al. 2004); in West Azerbaijan, Iran, the infusion of dried flowers is recommended for the treatment of haemorrhoids, dyspepsia, dysmenorrhoea and gastritis (Miraldi et al. 2001); in the Parvati valley, west Himalaya, India, leaves and flowers are employed for gastric problems and fever (Sharma et al. 2004). Yarrow (*Achillea millefolium* L. s.l.) *Achillea millefolium* has a long history of use as traditional herb medicine even in veterinary medicine (Eghdami and Sadeghi 2010). Preparations in the form of infusions, decoctions, or fresh juices have been applied against anorexia, stomach cramps, flatulence, gastritis, enteritis, internal and external bleeding (coughing blood, nosebleed, haemorrhoidal and menstrual bleeding, bloody urine), wounds, sores, skin rash, as well as dog and snake bites. Yarrow has been used internally, usually as a tea, and externally as a lotion, ointment or poultice (Grieve 1971; Chandler et al. 1982a).

Yarrow has been used by native American Indians for treating bruises, burns, neck cramps, sprains and swollen tissues; healing wounds; and providing relief from rashes and itching of various causes (Chandler et al. 1982a). The plant was also a popular febrifuge and enjoyed some use in the treatment of the common colds, bloody urine, indigestion, bowel complaints,

earache, headache, sore throat, toothache, spitting blood, haemorrhage and haemorrhoids. A number of its minor uses indicate that the plant is capable of imparting an analgesic (local anaesthetic), abortive and/or antiinflammatory effect and as an emmenagogue, laxative, tonic, stimulant, eyewash, sleep aid, liver aid and kidney aid.

Other Uses

Yarrow can be used as ground cover plant to combat soil erosion as it spreads rapidly and is drought resistant. It is also used as a companion plant as it repels bad insect pests and attracts beneficial predatory insects, such as ladybird beetle and parasitic wasps. The plant has been burnt in order to ward off mosquitoes. The plant and leaves can be used as compost and the leaves soaked in water to prepare a liquid leaf fertilizer for plants. The leaves contain essential oil and have been used as a cosmetic cleanser for greasy skin. The dried flowers and fresh foliage make attractive additions to floral arrangements. Yellow and green dyes are extracted from the flowers. The fragrant seeds have been used to impart a pleasant odour indoors.

Comments

In Australia, yarrow (*Achillea millefolium*) is deemed an environmental weed in Victoria, the ACT, and the southern parts of New South Wales. Though this species is naturalized in many parts of southern Australia, it is only considered to be a serious problem in the alpine and highland regions of southeastern Australia.

Acmella oleracea

Scientific Name

Acmella oleracea (L.) R.K. Jansen

Synonyms

Anacyclus pyrethraria (L.) Spreng., *Bidens fer-vida* Lam., *Bidens fusca* Lam., *Cotula pyrethraria* L., *Isocarpha pyrethraria* (L.) Cass., *Pyrethrum spilanthus* Medik., *Spilanthes acmella* auct. non (L.) Murr., *Spilanthes acmella* var. *oleracea* (L.) C.B.Clarke, *Spilanthes acmella* var. *oleracea* (L.) C.B.Clarke ex Hook.f., *Spilanthes fusca* hort.par. ex Lam., *Spilanthes oleracea* var. *fusca* (Lam.) DC., *Spilanthes radicans* Schrad. ex DC. (Illeg.)

Family

Asteraceae

Common/English Names

Brazil Cress, Eyeball Plant, Para Cress, Peek-A-Boo Plant, Perennial Para Cress, Spot Flower, Toothache Plant

Vernacular Names

Brazil: Abecedária, Agrião-Do-Pará, Jambu, Jambú, Jambu-Açu, Jambú Do Rio, Pimenteira (Portuguese)

Burmese: Hankala

Catalan: Creixans Del Para

Chinese: Jin Chou Kou, Liu Shen Cao, Qian Ri Ju, Yin Du Jin Niu Kou

Cuba: Cabrito

Czech: Plamatka

Danish: Parakarse

Dutch: ABC-Kruid, Braziliaanse Cresson, Huzarenknoop, Paratuinkers

Estonian: Harilik Nööpkakar

Fiji: Mbotembotekoro

Finnish: Parakrassi, Spilantes

French: Brede Mafane, Cresson De Para, Spilanthe Des Potagers, Cresson De Para, Cresson Du Brazil Cresson Du Para, Spilanthe Des Potagers

German: Husarenknopfblume, Parakresse, Prickelknöpfchen, Prickelblume

Hungarian: Abécefü, Huszárgomb, Szenyefű

India: Pirazha (Assamese), Akarkar, Pipulka (Hindi), Hemmugalu (Kannada), Leishabi (Manipuri), Acharbomdi, Akalkarra, Pipu-Labo (Marathi), Tefu Mozitang (Naga, Changki), Sarahattika (Sanskrit), Vana-Mugali (Tamil)

Indonesia: Gletang, Legetan, Sarunen, Saruni (Javanese), Jotang (Sundanese), Gatang (Sumatra)

Italian: Spilante

Japanese: Hokoso, Kibana-Oranda-Senniti, Oranda-Senniti

Korean: Parakuresu

Laos: Kh'aad

Lithuanian: Spilantė, Indienų Kresonas

Madagascar: Brède Mafana, Brèdes Mafanes (French)

Malaysia: Getang, Kerabu, Pokok Getang, Pokok Jotang

Nepal: Bhuin Timur, Lato ghans, Marati, Purple jhar

Peru: Bottoncillo, Botton De Oro, Chimaya, Cobiriqui, Contrayerba, Deflamatoria, Mata Gusanos, Somam, Yerba Del Espanto, Yuyo Quemada

Philippines: Dila-Dilag (Ifugao), Biri (Igorot), Gatang-Gatang, Pilet-Pilet (Sulu)

Portuguese: Agrião-Do-Brasil, Agrião Do Pará, Berro De Pará, Botão-De-Ouro, Botón De Oro, Cabrito, Espilanto, Hierba Del Espanto, Inambu, Jambú, Jambú Do Rio, Jambuaçu, Jamburana, Nambu, Nhambu, Pimenteira, Pimenteira Do Pará, Remedio De Los Pobres

Reunion Islands: Brède Mafane (French)

Russian: Spilantes, Maslyanyj Kress, Brazilski Kress

Spanish: Jambu

Sri Lanka: Akmaella (Sinhala), Akkirakara (Tamil)

Swedish: Parakrasse, Tandvärksplanta

Thai: Phak Khrat, Phak Phet, Phak tumhu, Phakkhraathuahaeun, Ya tumhu

Vietnamese: Cúc Áo, Cúc Nút Áo, Núc Áo Rau, Rau Cúc Áo

including America, Northern Australia, Africa, Southeast Asia, India and Sri Lanka.

Agroecology

The plant occurs at low to 1,200 m altitudes. It is found in moist, damp environment, in villages, pastures, rice fields and cultivated areas, along ditches, marshy meadows, open waste places, old clearings, on open hillsides and the rocky shores of rivers, and along roadsides. It thrives best in soil rich in compost. It is frost-sensitive but perennial in warmer climates.

Edible Plant Parts and Uses

Leaves and young shoot tips are eaten raw or cooked. In the United States, the leaves are used raw as a pungent flavouring for salads (Bailey 1949) and in India as a cooked vegetable (CSIR 1976) in soups and meats (Jansen 1985). In the Indian Ocean islands (Comoros, Madagascar, Réunion, Mauritius), the main use of the leaves is as a steamed vegetable. Both fresh and cooked leaves are used in the culinary dishes of the indigenous people in Brazil particularly in the provinces of Acre, Amazonas, Pará and Ceará (Benwick 2007). For instance, in the state of Pará, paracress is often consumed with chillies and garlic. Paracress is used in a fried duck-manioc dish called 'tucupí'. Another dish where paracress is used is 'tacacá', a soup thickened with manioc juice that contains dried shrimps and sometimes freshwater fish. In Java, Indonesia, the leaves and young shoots are served raw in 'lalab' served with other vegetables and eaten with a sambal (chilli sauce) (Ochse and Bakhuizen van den Brink 1980). The leaves of another closely related species *S. paniculata* (not *A. oleracea*) are used as cooked vegetables in Assam by the Bodo community (Patiri and Borah 2007) and in Southeast Asia (Roemantyo 1994).

The flowers are also edible (Deane 2007–2012; Benwick 2007; Wetwitayaklung et al. 2008; Toothman 2009; Burdock 2010). In Thailand,

Origin/Distribution

The plant is native to Brazil. It has been introduced across the tropics, and in Africa, escapes from cultivation have been reported. The plant is now grown both in the tropics and subtropics

leaves and flower heads are cooked as vegetables and used in curries (Wetwitayaklung et al. 2008). The flowers are used as spice for foods and dentifrice flavouring in Japan (Burdock 2010). Consumption of portions or whole flower buds known as Buzz Buttons, Szechuan Buttons, Sansho Buttons and Electric Buttons have been reportedly used to offset the intense heat of chillies and peppers (Benwick 2007; Toothman 2009). Eating a whole flower bud results in a grassy taste, followed by an extremely strong tingling or numbing sensation and often excessive saliva production and a cooling sensation in the throat. Benwick (2007) reported that a dish of eel basted in a thick, sweet sauce with Szechuan Button flowers and roast pineapple won 'Sushi of the Year' honours in Britain's annual Sushi Awards, sponsored by Eat-Japan. These buds are also used in drinks, cocktails, sorbets (Benwick 2007; Toothman 2009) and an Alaskan halibut curry dish (Toothman 2009). In India, the buds and oleoresins are used as flavouring in chewing tobacco.

Botany

An erect, or decumbent, stout, branched, annual herb, 20–80 cm high. Leaves, opposite, glabrous, simple, broadly ovate to triangular, 5–11 cm long, 4–8 cm wide, base truncate, apex acute, margin serrate (Plate 1). Inflorescence, solitary, axillary or terminal, a globose capitulum up to 2.5 cm across becoming ovoid or conical, with an obtuse or rounded apex (Plates 1 and 2), when young two-coloured with a purplish apex, afterwards uniformly yellow, on long peduncle up to 12 cm long. Involucre shallowly campanulate, involucre bracts 15–18, in 2–3 series, oblong-lanceolate, ciliate. Ray florets very often deficient or if present 3–5 minutes, female, tubular yellowish-green base and yellowish limb. Disk florets numerous up to 600, bisexual, corolla 4–5-merous, up to 3.5 mm long, yellow, occasionally with purplish-red palea in immature capitulum, ovary compressed, style bifid. Achenes flattened ellipsoid, dark brown, 2–2.5 mm long, pappus with two short bristles.

Nutritive/Medicinal Properties

Flower Phytochemicals

The structure of spilanthol, the pungent, insecticidal constituent of the flower heads was shown to be *N*-isobutyldeca-2, 6,8-trienamide and

(Jacobson 1957; Yasuda et al. (1980) and to be identical with that of affinin obtained from roots of *Heliopsis longipes* (Jacobson 1957). Two sesquiterpenes, with structures identical to polygodial and eudesmanolide, were isolated from the flower heads of *S. acmella* together with spilanthol (Nagashima and Nakatani 1992b). Spilanthol and three pungent alkamides (2*E*-*N*-(2-methylbutyl)-2-undecene-8,10-diynamide; 2*E*,7*Z*-*N*-isobutyl-2,7-tridecadiene-10,12-diynamide; and 7*Z*-*N*-isobutyl-7-tridecene-10,12-diynamide) (Nakatani and Nagashima 1992) and spilanthol plus six alkylamides were isolated from the flower head (Nagashima and Nakatani 1992a). Three *N*-isobutyl amides spilanthol, undeca-2*E*,7*Z*,9*E*-trienoic acid isobutylamide and undeca-2*E*-en-8,10-diynoic acid isobutylamide were isolated from the dried flower buds (Ramsewak et al. 1999). Three alkamide compounds were identified from the flower head: *N*-isobutyl-2,6,8-decatrienamide (compound 1), undeca-2*E*,7*Z*,9*E*-trienoic acid isobutylamide (compound 2) and (2*E*)-*N*-(2-methylbutyl)-2-undecene-8,10-diynamide (compound 3) (Pandey et al. 2011). The amount of the compounds obtained were 338 mg (compounds 1 and 2) and 188.4 mg (compound 3), respectively. A mixture of C22–C35 normal hydrocarbons was isolated from *S. acmella* flower heads (Baruah and Pathak 1999).

Eight *N*-isobutylamides, two 2-methylbutylamides and one 2-phenylethylamide were detected, with spilanthol as most abundant *N*-alkylamide (88.8 %) in *S. acmella* ethanol flower extract (Boonen et al. 2010a). The *N*-alkylamides included the following: (2*E*,6*Z*,8*E*)-*N*-isobutyl-2,6,8-decatrienamide (spilanthol); (2*E*,4*E*,8*Z*,10*Z*)-*N*-isobutyl-dodeca-2,4,8-10-tetraenamide; (2*E*,7*Z*)-*N*-isobutyl-2,7-tridecadiene-10,12-diynamide; (2*E*,4*Z*)-*N*-isobutyl-2,4-undecadiene-8,10-diynamide; (2*E*,6*Z*,8*E*)-*N*-(2-methylbutyl)-2,6,8-decatrienamide; 2(*Z*)-*N*-isobutyl-2-nonene-6,8-diynamide; *N*-phenylethyl-2,3-epoxy-6,8-nonadiynamide; (2*E*)-*N*-isobutyl-2-undecene-8,10-diynamide; (2*E*)-*N*-(2-methylbutyl)-2-undecene-8,10-diynamide; and two unidentified alkylamides. Five *N*-isobutylamides, one 2-methylbutylamide and one 2-phenylethylamide were identified in

the ethanol extracts of *Spilanthus acmella* flowers (Sharma et al. 2011). These included (2*E*,6*Z*,8*E*)-*N*-isobutyl-2,6,8-decatrienamide (spilanthol); (2*E*,4*E*,8*Z*,10*Z*)-*N*-isobutyl-dodeca-2,4,8,10-tetraenamide; (2*E*,7*Z*)-*N*-isobutyl-2,7-tridecadiene-10,12-diynamide; (2*Z*)-*N*-phenethyl-2-nonene-6,8-diynamide; (2*E*,4*Z*)-*N*-isobutyl-2,4-undecadiene-8,10-diynamide; (2*E*,7*Z*)-*N*-isobutyl-2,7-decadienamide; and (2*E*,6*Z*,8*E*)-*N*-(2-methylbutyl)-2,6,8-decatrienamide. The following alkylamides were identified from the methanol flower extract of *S. acmella*: spilanthol (0.07 %), (*Z*)-non-2-en-6,8-diynoic acid isobutylamide (0.01 %), (2*E*)-*N*-isobutylundeca-2-ene-8,10-diynamide (0.01 %) and spilanthic acid 2-methylbutylamide (0.04 %) (Mbeunkui et al. 2011). Supercritical fluid extraction using CO₂ showed *S. acmella* flowers were richer in spilanthol than leaves and stems and presented the highest antioxidant/total phenolic ratio as well as the highest antiinflammatory activity (Dias et al. 2012). Approximately 95 % of the total amount of extracted spilanthol was obtained during the SFE(CO₂) extraction step.

Twenty compounds were identified in the essential oil from *S. acmella* flower heads; limonene (23.6 %), β-caryophyllene (20.9 %), (*Z*)-β-ocimene (14.0 %), germacrene D (10.8 %) and myrcene (9.5 %) were found to be the major constituents of the oil (Baruah and Leclercq 1993).

Leaf Phytochemicals

Ethanol leaf extract of *Acmella oleracea* afforded a larvicidal hexane fraction (LC₅₀=145.6 ppm) and a nonlarvicidal dichloromethane one (Simas et al. 2013). From the inactive fraction, three amides were identified, deca-6,9-dihydroxy-(2*E*,7*E*)-dienoic acid isobutylamide; deca-8,9-dihydroxy-(2*E*,6*Z*)-dienoic acid isobutylamide; and the known nona-2,3-dihydroxy-6,8-diynoic acid 2-phenylethylamide. From the hexane partition mixture of two acetylenic 2-phenylethylamides, nona-(2*Z*)-en-6,8-diynoic acid 2-phenylethylamide and deca-(2*Z*)-en-6,8-diynoic acid 2-phenylethylamide were isolated. Studies by Singh and Chaturvedi (2012) showed

that in-vitro tissue cultures of *S. acmella* could be utilized for spilanthol production, an alkylamide used in cosmetics. Significantly higher amount of spilanthol was found in in-vitro plantlet leaves (3294.36 µg/g DW) compared to those taken from field-grown mother plants (2703.66 µg/g DW).

Fourteen volatile compounds isolated from the essential leaf oil of *S. acmella* are as follows: germacrene-D 54.38 %, *trans*-β-caryophyllene 15.58 %, β-elemene 4.53 %, nor-copaanone 2.44 %, bicyclogermacrene 2.15 %, valencene 2.14 %, unidentified 1.66 %, α-humulene 1.53 %, *cis-trans*-α-bisabolene 1.34 %, 2-tridecanone 1.25 %, caryophyllene oxide 1.23 %, neophytadiene 1.21 %, δ-cadinene 1.09 % and β-oplophenone 1.02 % (Kawaree et al. 2008). Three alkamide compounds were identified from the flower head: *N*-isobutyl-2,6,8-decatrienamide (compound 1), undeca-2*E*,7*Z*,9*E*-trienoic acid isobutylamide (compound 2) and (2*E*)-*N*-(2-methylbutyl)-2-undecene-8,10-diynamide (compound 3) (Pandey et al. 2011). The amount of the compounds obtained were 338 mg (compounds 1 and 2) and 188.4 mg (compound 3), respectively.

Plant (Aerial Parts) Phytochemicals

β-Sitosterol, stigmasterol, fatty acid esters of α- and β-amyrin, myricyl alcohol, stigmasterol and stigmasteryl glucoside including β-sitosteryl-3-*O*-β-D-glucoside (Krishnaswamy et al. 1975), and stigmasterol and myricyl alcohol (Tiwari and Kakkar 1990) were isolated from *S. acmella*. In addition to spilanthol [= affinin, (2*E*,6*Z*,8*E*)-deca-2,6,8-trienoic acid isobutylamide], the corresponding 2-methyl-butylamide and two new acetylenic alkamides, namely, (*Z*)-non-2-en-6,8-diynoic acid isobutylamide and (*Z*)-dec-2-en-6,8-diynoic acid isobutylamide, were isolated from *Spilanthes oleracea* (Greger et al. 1985).

Fractionation of the chloroform extract of *S. acmella* aerial parts afforded stigmasterol, stigmasteryl-3-*O*-β-D-glucopyranoside together with a mixture of long-chain hydrocarbon esters (Prachayasittikul et al. 2009). Fractionation of the ethyl acetate extract gave three compounds:

3-acetylaleuritic acid, vanillic acid and β-sitostenone. The methanol extract fractions provided four compounds: scopoletin, *trans*-ferulic acid, *trans*-isoferulic acid and a mixture of stigmasteryl-3-*O*-β-D-glucopyranoside and β-sitosteryl-3-*O*-β-D-glucopyranoside.

Besides the long known tingling compounds (2*E*,6*Z*,8*E*)-deca-2,6,8-trienoic acid *N*-isobutyl amide (spilanthol) and (2*E*,6*Z*,8*E*)-deca-2,6,8-trienoic acid *N*-(2-methylbutyl) amide, as a minor constituent, a new 2-ketol ester (7*Z*,9*E*)-2-oxo-undeca-7,9-dienyl 3-methylbut-2-enoate (acmellonate) was isolated from the plant (Ley et al. 2006). Acmellonate elicited a weak tingling and numbing effect on the tongue and contributed only to a small extend to the overall flavour of the plant. The following three alkamides were isolated from a hexane extract of the aerial parts of *A. oleracea*: spilanthol; (*E*)-*N*-isobutylundeca-2-en-8,10-diynamide; and (*R*,*E*)-*N*-(2-methylbutyl) undeca-2-en-8,10-diynamide. Spilanthol and undeca-2*E*-ene-8,10-diynoic acid isobutylamide were isolated from the water extract of *S. acmella* (Spelman et al. 2011). Spilanthol was only detected in *S. acmella* mother plants, flower heads and in-vitro plantlets but was not found in the callus or cell cultures (Tan et al. 2011). However, *N*-isobutyl-2*E*, 4*Z*, 8*Z*, 10*E*-dodecatetraenamide was absent in mother plants but could be detected in the in-vitro plantlets. The antioxidant butylated hydroxytoluene (BHT) and fatty acids, *n*-hexadecanoic acid (palmitic acid) and tetradecanoic acid, were found in each of the sample extracts, namely, mother plant, flower heads, in-vitro plantlets, callus, air-dried cells, freeze-dried cells and fresh cells.

Eighteen compounds were identified from the essential oil of *Spilanthes acmella* (Lemos et al. 1991). The major constituents identified were β-caryophyllene (30.2 %), γ-cadinene (13.3 %) and thymol (18.3 %). More than 45 components were identified from essential oil of the fresh plant of *Spilanthes acmella* from southern India (Jirovetz et al. 2005). The compounds included (*E*)-2-hexenol (25.7 %), 2-tridecanone (13.1 %), germacrene D (11.1 %), hexanol (11.0 %), β-caryophyllene (10.8 %) and (*Z*)-3-hexenol (5.1 %) as significantly dominating compounds.

Additional components responsible for the characteristic aroma impressions were especially C6–C9 derivatives, mono- and sesquiterpenes.

Antioxidant Activity

The volatile leaf oil of *S. acmella* possessed both of the highest antioxidant activity in all three assays, as well as the total phenolic compounds (Kawaree et al. 2008). Antioxidant activity of the leaf essential oil was 276.09 μmol Trolox equivalent/g in the 2,2'-azino-bis (3-ethylbenzo-thiazoline-6-sulfonic acid) diammonium salt (ABTS) assay; the ferric reducing antioxidant power (FRAP) assay was 35,465 $\mu\text{mol/g}$ EC1 (equivalent concentration); lipid peroxidation (β -carotene bleaching assay) was 61.55 % AA (antioxidant activity); and total phenolic content was 308.03 mg gallic acid equivalent/g. Fractions from the chloroform, ethyl acetate and methanol extracts of *S. acmella* aerial parts displayed antioxidant activity in the 2,2-diphenyl-1-picrylhydrazyl (DPPH) and superoxide dismutase assays (Prachayasittikul et al. 2009). The ethyl acetate and methanol extract and fractions exhibited the most potent DPPH radical scavenging activity. No cytotoxic effects of the extracts against KB (human oral carcinoma) and HuCCA-1 (human cholangiocarcinoma) cell lines were evident.

Callus from leaf explants and plant parts (root, stem, leaf) of *S. acmella* were used for quantitative estimation of primary metabolites and antioxidant activity (Tanwer et al. 2010). Methanol extract of stem showed highest superoxide radical scavenging activity (39.54 %), while leaves have showed maximum (76.42 %) DPPH scavenging activity compared to other plant parts and callus. Maximum soluble sugars (51 mg/g DW) in callus, starch (30 mg/g DW) in stem, protein (25 mg/g DW) and phenolic contents (52.3 mg/g DW) in leaves and lipids (80 mg/g DW) in roots were determined.

Vasorelaxation/Spasmolytic Activity

Studies by Wongsawatkul et al. (2008) demonstrated that *S. acmella* extract exerted maximal vasorelaxations in a dose-dependent manner

on phenylephrine-induced contraction of rat thoracic aorta. The effect was less than acetylcholine-induced nitric oxide (NO) vasorelaxation. Significant reduction of vasorelaxation was observed in both N(G)-nitro-L-arginine methyl ester (L-NAME) and indomethacin (INDO). In the presence of L-NAME plus INDO, synergistic effects were observed, leading to loss of vasorelaxation of both acetylcholine and the extracts. The extract was found to exhibit vasorelaxation via partially endothelium-induced NO and prostacyclin in a dose-dependent manner. Further, the ethyl acetate extract exerted immediate vasorelaxation (ED_{50} 76.1 ng/ml) and was the most potent antioxidant in the DPPH assay. The chloroform extract showed the highest vasorelaxation and antioxidant in the SOD (superoxide dismutase) assay.

Antiinflammatory Activity

Studies showed that spilanthol, isolated from *S. acmella*, attenuated the lipopolysaccharide (LPS)-induced inflammatory responses in murine RAW 264.7 macrophages partly due to the inactivation of NF-kappaB, which negatively regulated the production of proinflammatory mediators at the transcriptional and translational levels (Wu et al. 2008). Additionally, the LPS-stimulated IL-1beta, IL-6 and TNF-alpha productions were dose dependently reduced by spilanthol.

Aphrodisiac Activity

The orally administered ethanol extracts of the *Spilanthes acmella* flower extract had a dose-dependent positive effect on mounting frequency, intromission frequency and ejaculation frequency of normal male Wistar albino rats (Sharma et al. 2011). The most significant effects were observed at 150 mg/kg treatment, even after a lapse of 7 and 14 days of discontinuance of drug treatment. A dose-dependent effect was also observed on the follicle-stimulating hormone (FSH) and luteinizing hormone (LH) and testosterone serum

levels. In-vitro nitric oxide release was 21.79 μM , which was significantly higher compared to the control group. The aphrodisiac potential of an ethanol *Spilanthes acmella* extract was demonstrated in-vitro and in vivo. *N*-alkylamides might attribute to the improved sexual potential. The results supported traditional use of *S. acmella* as a sexual stimulating agent.

Transdermal/Transmucosal Activity

The *N*-alkylamide spilanthol from *S. acmella* was demonstrated to permeate human skin in a Franz diffusion cell (FDC) system thereby supporting its topical application usage on the skin (Boonen et al. 2010b). Spilanthol from *S. acmella* ethanol extract was demonstrated to permeate porcine buccal mucosa in a Franz diffusion cell experimental setup (Boonen et al. 2010a).

Convulsant Activity

The hexane extract of *Spilanthes acmella* var. *oleracea* when injected intraperitoneally induced full tonic-clonic convulsions in male Wistar rats in a dose-dependent manner indicating the potential for its use as a tool in the development of new models of epilepsy (Moreira et al. 1989).

Diuretic Activity

Spilanthes acmella cold water extract caused marked increase in urinary Na^+ and K^+ levels in rats and a reduction in the osmolarity of urine suggesting that it was mainly acting as a loop diuretic and may also inhibit antidiuretic hormone release and/or action (Ratnasooriya et al. 2004). The results suggested that *Spilanthes acmella* had strong diuretic action. Administration of the petroleum ether, chloroform and alcohol leaf extracts of *S. acmella* to rats caused an increase in total urine volume and electrolytes excretion (sodium Na^+ , potassium K^+ and chloride Cl^-) (Yadav et al. 2011b). Among the different extracts, the alcohol extract (500 mg/kg)

significantly and markedly increased the urine output. The pattern of diuresis induced by the alcohol extract was almost similar to that produced by the furosemide.

Drug Interaction Activity

The alkylamides present in *S. acmella* showed significant inhibition of cytochrome P450(2E1)-mediated oxidation of *p*-nitrophenol in-vitro at concentrations as low as 25 μM , whereas the caffeic acid derivatives had no effect (Raner et al. 2007).

Gastroprotective Activity

A rhamnogalacturonan polysaccharide containing uronic acid, galactose, arabinose, rhamnose and glucose in a 15:2:1:1:0.5 M ratio and with molecular weight 226,000 g/mol exhibited gastroprotective activity (Nascimento et al. 2013). The rhamnogalacturonan was found to compose of a long chain of $\rightarrow 4$)-6-OMe- α -D-GalpA-(1 \rightarrow , interspersed with some α -L-Rhap residues, partly substituted by side chains of type II arabinogalactans.

Anti-obesity Activity

The ethanol extract of *S. acmella* flower buds exhibited pancreatic lipase inhibitory activities in a concentration-related manner in the range 0.75–2.0 mg/ml (Ekanem et al. 2007).

Immunomodulatory Activity

The ethanol leaf extract of *S. acmella* (500 mg/kg b.wt. p.o.) exhibited significant peritoneal macrophage stimulation and 25–50 % mortality as compared to control mice, indicating its prominent immunostimulant activity (Savadi et al. 2010). Rats orally administered with the ethanol leaf extract of *S. acmella* showed a significant increase in neutrophil adhesion, haemagglutinating antibody

titre (HAT) and delayed-type hypersensitivity (DTH) response (Yadav et al. 2011a). In rats immunized with sheep red blood cells (RBC), the extract enhanced the humoral antibody response to the antigen and significantly potentiated the cellular immunity by facilitating the footpad thickness response to sheep RBC in sensitized rats. With a dose of 500 mg/kg body weight, the values of neutrophil adhesion, HAT and DTH responses were statistically significant as compared to control. The results demonstrated the immunomodulatory potential of *Spilanthes acmella* in rats.

Anaesthetic and Antipyretic Activities

S. acmella aqueous extracts in concentrations of 10 and 20 % produced 70.36 and 87.02 % anaesthesia, respectively, by the intracutaneous wheal compared to 97.22 % anaesthetic effect produced by 2 % xylocaine (Chakraborty et al. 2010). The mean onset of anaesthesia with the test drug was 5.33 minutes compared to 2.75 minutes for the standard drug in the plexus anesthesia model. In the antipyretic model, the extract in doses of 100, 200 and 400 mg produced dose-dependent reduction in mean temperature at various hours of observation. The results suggested that *S. acmella* aqueous extract had significant local anesthetic and antipyretic activities.

Analgesic Activity

The water extract of *S. acmella* flowers exerted an analgesic effect in rats administered orally with the extract (Peiris et al. 2001). A dose-dependent analgesic activity with a EC_{50} = 313 mg/kg was evident when evaluated in hot plate but not in tail-flick test. This analgesic activity had a rapid onset and short duration of action and was not blocked by naloxone, an opioid receptor antagonist. The mid dose of the extract also induced significant sedation as evaluated using rat hole-board technique. It was concluded that the analgesic activity was mediated supraspinally accompanied with sedation.

Antimicrobial Activity

The petroleum ether *S. acmella* flower extract was found to inhibit growth in-vitro of *Fusarium oxysporum*, *Fusarium moniliforme*, *Aspergillus niger* and *Aspergillus parasiticus* (Rani and Murty 2006). Prasad and Seenayya (2000) reported that *S. acmella* possessed good growth inhibitory activity against red halophilic cocci *Salinicoccus roseus*, *Halococcus turkmenicus* and *Halococcus morrhuae* from salt-cured fish. Studies showed that fractions from the chloroform and methanol extracts of *S. acmella* plant inhibited the growth of many tested organisms, e.g., *Corynebacterium diphtheriae* with minimum inhibitory concentration (MIC) of 64–256 mg/ml and *Bacillus subtilis* with MIC of 128–256 mg/ml (Prachayasittikul et al. 2009). The hexane and chloroform extracts completely inhibited the growth of *Saccharomyces cerevisiae* with MIC 256 µg/ml. The chloroform extract also completely inhibited growth of *Streptococcus pyogenes* II with MIC 256 µg/ml. Further, a methanol fraction also inhibited the growth of *Micrococcus luteus*, *Staphylococcus epidermidis* and *B. cereus* with MIC 128–256 µg/ml.

Insecticidal Activity

Infrared spectra of spilanthal from *Spilanthes* spp. and of a sample of affinin obtained from roots of *Heliopsis longipes* were superimposable, and both materials gave the same high knock-down and kill in tests against houseflies (*Musca domestica*) and mosquito larvae (Jacobson 1957). *S. acmella* extract was shown to be toxic against adults of American cockroach, *Periplaneta americana* (Kadir et al. 1989). *N*-isobutyl-2,6,8-decatrienamide (spilanthal) was found to be the active component. Topical application of spilanthal produced high acute toxicity, and spilanthal was more potent compound compared to three conventional insecticides. The potency was found to be 1.3, 2.6 and 3.8 times more toxic than carbaryl, bioresmethrin and lindane, respectively. Electrophysiological studies indicated immediate

hyperexcitation followed by complete inhibition of the cockroach cercal nerve activity by the extract.

Spilanthes acmella exhibited marked larvicidal effect on the fourth instar larvae of *Culex quinquefasciatus* with an LC_{50} value of 61.43 ppm (Pitasawat et al. 1998).

Three *N*-isobutyl amides spilanthal, undeca-2*E*,7*Z*,9*E*-trienoic acid isobutylamide and undeca-2*E*-en-8,10-diynoic acid isobutylamide were isolated from the dried flower buds (Ramsewak et al. 1999). All were active against *Aedes aegypti* larvae and *Helicoverpa zea* neonates at 12.5 and 250 μ g/ml concentrations, respectively. Spilanthal, a major constituent of *S. acmella* ethanol flower extract, found to have potent ovicidal, larvicidal and pupicidal activity (Saraf and Dixit 2002). Maximum 7.5 ppm concentration caused 100 % motility of eggs, larvae and pupae of *Anopheles*, *Culex* and *Aedes* mosquitoes. Spilanthal was more effective even at low doses against eggs and pupae.

The following three alkamides from a hexane extract of the aerial parts of *A. oleracea*, spilanthal; (*E*)-*N*-isobutylundeca-2-en-8,10-dynamide; and (*R*, *E*)-*N*-(2-methylbutyl)undeca-2-en-8,10-dynamide, exhibited insecticidal activity, with spilanthal being the most active (LD_{50} =0.13 μ g/mg) against *Tuta absoluta* (Moreno et al. 2012). The alkamides were selective to both beneficial non-target species, the predator *Solenopsis saevissima* (Hymenoptera: Formicidae) and to the pollinator *Tetragonisca angustula* (Hymenoptera: Apidae, Meliponinae) studied.

Of three *Spilanthes* species, *S. acmella* L.var *oleraceae* Clarke, *S. calva* L. and *S. paniculata* Wall ex DC, *S. acmella* hexane flower extract was the most effective in inducing complete lethality at minimum doses, the respective LC_{50} and LC_{90} values being 4.57 and 7.83 (*Anopheles stephensi*), 0.87 and 1.92 (*Anopheles culicifacies*) and 3.11 and 8.89 ppm (*Culex quinquefasciatus*). This was followed by *S. calva* and *S. paniculata* extracts, respectively (Pandey et al. 2007). Three alkamide from the flower head *N*-isobutyl-2,6,8-decatrienamide; undeca-2*E*,7*Z*,9*E*-trienoic acid isobutylamide; and (2*E*)-*N*-(2-methylbutyl)-2-undecene-8,10-dynamide

exhibited larvicidal activity against late III/early IV instar *Anopheles stephensi* larvae (Pandey et al. 2011). A mixture of two acetylenic 2-phenylethylamides, nona-(2*Z*)-en-6,8-diynoic acid 2-phenylethylamide and deca-(2*Z*)-en-6,8-diynoic acid 2-phenylethylamide, isolated from the hexane fraction of the ethanol leaf extract were active against *Aedes aegypti* mosquito larvae at LC_{50} =7.6 ppm (Simas et al. 2013). They were not toxic to *Artemia salina nauplii* indicating the possibility of using the compounds to control *Aedes aegypti* larvae.

Antiplasmodial Activity

Centrifugal partition chromatography (CPC) fractions from the methanol flower extract, which contained natural mixtures of phytochemicals, demonstrated significantly higher antiplasmodial activity compared to corresponding purified *N*-alkylamides, thus suggesting that interactions between these *N*-alkylamides may potentiate antiplasmodial bioactivity (Mbeunkui et al. 2011). The isolated alkylamides, spilanthal and undeca-2*E*-ene-8,10-diynoic acid isobutylamide, from *S. acmella*, were shown to have IC_{50} s of 16.5 and 41.4 μ g/ml on *Plasmodium falciparum* strain PFB and IC_{50} s of 5.8 and 16.3 μ g/ml for the chloroquine-resistant *Plasmodium falciparum* K1 strain, respectively (Spelman et al. 2011). Further, at relatively low concentrations, spilanthal and *S. acmella* water extract reduced the parasitemia 59 and 53 % in mice infected with *Plasmodium yoelii yoelii* 17XNL at 5 and 50 mg/kg, respectively.

Malarial 5 is a traditional Mali drug composed of *Cassia occidentalis* leaves, *Lippia chevalieri* plant and *Spilanthes oleracea* flower heads, administered as a decoction (Gasquet et al. 1993). The drug and its individual plant components were inhibitory in-vitro to *Plasmodium falciparum* with an IC_{50} of 500 μ g/ml for the drug and 200–400 μ g/ml for *Lippia chevalieri* and *Spilanthes oleracea*. In the in-vivo assay with *P. berghei* in mice, mice treated with 200 mg of lyophilized Malarial 5 over 5 days survived for 2–3 days longer than controls.

Traditional Medicinal Uses

The flowers and leaves of *Spilanthes acmella* have a pungent taste accompanied by tingling and numbness and have been used as a spice for appetizers and as widespread folk medicine for stammering, toothache, stomatitis and throat complaints (Nakatani and Nagashima 1992; Wu et al. 2008). The leaves of *Spilanthes acmella* have been used traditionally as tonic and in the treatment of rheumatism, gout and sialagogue (Savadi et al. 2010). The plant has anaesthetic action and is used for toothache in the East (Burkill 1966). In India, the plant is used as a sialagogue to increase salivation and stimulation for curing headaches, paralysis of the tongue and affections of the throat. In Java, the dried flower heads are used for sore mouth of sprue. A decoction of the plant can be taken internally as a diuretic and able to resolve stones in the bladder, while a decoction of the roots can be used as a purgative. A decoction of the plant is used as vulnerary and also regarded as an antiscorbutic. The plant is also used as a cure for dysentery and rheumatism and to enhance the immune system. It is used against blood parasites, especially against malaria, both prophylactic and curative.

Other Uses

Acmella oleracea is widely grown as an ornamental (and occasionally as a medicinal) in various parts of the world. In India, the crushed plant is used as a fish poison.

Peptides derived from *A. oleracea* plant extracts are used in a cosmetic composition (in anti-wrinkle cream and antiaging formulations) to help regenerate the dermal matrix and accelerate repair of functional wrinkles (Demarne and Passaro 2005; Belfer 2009). Besides these medicinal uses, the flower heads have been used as a spice for appetizers by the Japanese, and spilanthol-rich extract and essential oil of the plant was used as a flavouring material for dentifrices, mouthwash, chewing gum and breath fresheners (Lion 1985; Shimada and Gomi 1995).

The plant contains *N*-alkylamides (NAAs) which have been regarded to be a promising group of bioactive compounds, which are anticipated to act as important lead compounds for plant protection and biocidal products, functional food, cosmeceuticals and drugs in the next decade (Boonen et al. 2012).

Comments

Several closely *Acmella* species in South America, Africa and Southeast Asia have similar culinary, medicinal and ornamental uses.

Origin/Distribution

The species is native to tropical Central and South America and is now found naturalized pan-tropically in disturbed areas as weeds. It is common in the warm tropics throughout Africa, Asia and the South Pacific Islands.

Agroecology

It occurs in the warm tropics from sea level to 2,000 m in wet and dry disturbed areas. It is usually found in waste places, gardens, old cultivations, grasslands, low secondary growth forests, forest edges, roadsides, water courses, etc., where there is ample exposure to sunlight (Dung et al. 1996). It also occurs as a major to intermediate weed in rice fields, orchards, plantations, pastures and cultivated vegetable and cropping areas. It thrives best in rich, moist, mineral soils in areas with high air humidity and tolerates shade.

Edible Plant Parts and Uses

The fragrant flowers and foliage are used for scenting edible coconut oil in the southeastern Polynesia (Brown 1935; Facciola 1990). The leaves are eaten in a soup called 'olulu-ogwai' by the Igbo communities in Nigeria (CINE 2007).

Botany

An erect, pubescent, aromatic, slender, annual herb sparingly branching 15–100 cm high. Stems and leaves covered with fine white hairs. Leaves simple, petiolate, green, ovate or rhomboid-ovate, 1–10 cm×0.5–7 cm, with crenate margin, acute apex and oblong or attenuate base, glandular dorsally (Plates 1 and 2). Inflorescence terminal corymb of 8–15 discoid heads, florets about 75 per head; corolla tubular, white or pale purple

Plate 1 Pale purple flower heads and leaves

Plate 2 Pale blue purple heads

or blue (Plates 1 and 2), 1–1.5 mm long, limb 5-cleft, included in the involucre; style branches exerted. The fruit (achene) linear-oblong, 1.5–2 mm long, black, 5 angled, nearly glabrous with scaly pappus.

Nutritive/Medicinal Properties

The proximate nutrient composition of the edible leaves was reported by CINE (2007) as moisture 42.5 g, energy 181 kcal, protein 6.9 g, fat 0.4 g, carbohydrate 37.5 g, fibre 0.1 g, ash 3.4 g, Ca 345 mg, P 725 g, Fe 10 mg and Zn 4.5 mg. The major amino acids present in free form in the pollens of *A. conyzoides* included arginine,

cystine, glutamic acid, glycine, isoleucine, leucine, methionine, ornithine, tryptophan, amino-n-butyric acid, aspartic acid, proline and tyrosine (Mondal et al. 1998).

Besides nutrients in the leaves (CINE 2007) and amino acids in the pollens, *Ageratum conyzoides* have been reported to contain chromenes, chromones, chromanones, benzofurans, flavonoids including highly methoxylated flavonoids, farnesene derivatives, monoterpenes, triterpenes, sesquiterpenes and phenylpropanoids, sterols, alkaloids and a raft of miscellaneous compounds in plant extracts, volatiles and essential oil extracted from various parts of the plant (Okunade 2003; Kamboj and Saluja 2008).

Essential Oils, Volatiles and Plant Extracts

The essential oil of *A. conyzoides* was found to contain 4–6 major compounds such as ageratochromene (about 53–55 %) and demethoxyageratochromene (about 30–32 %) (Pham and Nguyen 1976). The essential oil of *A. conyzoides* was reported to have complex mixture of 213 compounds of which 43–51 constituents have been reported (Kamboj and Saluja 2008). The constituents identified include 20 monoterpenes 6.4 % [13 monoterpenoid hydrocarbons (5.0 %), 7 oxygenated monoterpenoids (0.08–1.4 %)], 20 sesquiterpenes 5.1 % [16 sesquiterpenoid hydrocarbons (4.3 %), four oxygenated sesquiterpenoids (0.8 %)] and three phenylpropanoids and benzenoids (2.33 %).

Fifty-one constituents—13 monoterpenoid hydrocarbons (5.0 %), 7 oxygenated monoterpenoids (1.4 %), 16 sesquiterpenoid hydrocarbons (4.3 %), 4 oxygenated sesquiterpenoids (0.8 %), 3 phenylpropanoids and benzenoids (2.33 %), 6 chromenes (85.2 %) and 2 chromans (0.9 %)—were identified in the essential oil of *A. conyzoides* leaves in Nigeria (Ekundayo et al. 1988). The essential oils of fresh flowers and a combination of leaves plus stems of flowering and nonflowering *Ageratum conyzoides* in Fiji were found to be rich in sesquiterpenes and ageratochromene (6,7-dimethoxy-2,2-dimethylchromene) and 7-methoxy-2,2-dimethylchromene (Aalbersberg and Singh

1991). The main constituents in the essential oil of *Ageratum conyzoides* from Vietnam were ageratochromene (precocene II), 6-demethoxyageratochromene (precocene I) and β -caryophyllene, accounting for 77 % of the oil (Nguyễn et al. 1989). Two main components 7-methoxy-2,2-dimethylchromene (precocene I) and β -caryophyllene, a large number of terpenoids and some chromenes were identified in the essential oil of the whole plant (Vera 1993). Two new compounds, coumarin and phytol (a diterpene alcohol), were also identified. The natural occurrence of the two chromans, 6-acetyl-2,2-dimethyl-3,4-dihydro-chromene and its 7-methoxy derivative, was being reported for the first time. Forty-seven components making up of 96.35 % of the oil were identified in the essential oil of *Ageratum conyzoides* from Ghana essential oil of *Ageratum conyzoides* L. from Ghana (Mensah et al. 1993). The major constituents were 6-demethoxyageratochromene (precocene I) (80.29 %) and β -caryophyllene (7.04 %).

Main components of the essential oil of flowers and combination of stem and leaves from Pakistan were β -caryophyllene (14.35 %, 17 %), 6-demethoxy-ageratochromene (30.30 %, 26.60 %) and ageratochromene (34.90 %, 36.90 %), respectively (Riaz et al. 1995). The content of *A. conyzoides* essential oil extracted from the leaves and the roots varied from 0.11 to 0.58 % for the leaves and from 0.03 to 0.18 % for the roots (1996). Oils from leaves and roots show a certain homogeneity of chemical composition. Main constituents were β -caryophyllene (1.2–25.1 %) and precocene I (63.0–92.9 %). β -caryophyllene (10.5 %) and precocene I (81 %) were the major components of the leaf essential oil (Chalchat et al. 1997). Forty constituents comprising 13 monoterpenoids (5.17 %), 17 sesquiterpenoids (13.95 %) and 8 chromenes (71.05 %) were identified in the essential oil of *Ageratum conyzoides* leaves (Kasali et al. 2002).

Twelve components making up of 86–99 % of the essential oil in different plant parts of *Ageratum conyzoides* in Lucknow, namely, flowers, stems, leaves and roots, were identified (Singh et al. 2003). The major constituents were 6-demethoxyageratochromene (precocene I, 13.2–44.3 %)

and ageratochromene (precocene II, 41.1–62.2 %). Total chromene was found maximum in leaves (91.7 %) and minimum in roots. Precocene I (86 %) and β -caryophyllene (8 %) are major components of leaf essential oil (Nébié et al. 2004). The essential oil isolated from the leaves and flowers of *Ageratum conyzoides* in South China was found to contain ageratochromene (precocene II, 25.89 %), the sesquiterpene β -caryophyllene (23.79 %), demethoxyageratochromene (precocene I, 14.76 %) and some monoterpene hydrocarbons, with percentages of 2–5.5 % (Sundufu and Shoushan 2004). The essential oil of *A. conyzoides* obtained from 5 different areas in Brazil was found to contain 11 identified compounds and precocene I as the main constituent in the API accession and the precocene II as the main constituent in the other four accessions (De castro et al. 2004). The leaf essential oil of *A. conyzoides* from Brazil consisted exclusively of the chromenes precocene I (95.4 %) and II (4.5 %) (Lima et al. 2005). Forty-six compounds accounting for 97.60 % of the oil of the aerial parts of *Ageratum conyzoides* were identified (Rana and Blazquez 2003). The main compounds were found to be ageratochromene (32.9 %), 6-methoxyquinoline-1-oxide (20.77 %), β -caryophyllene (19.79 %), β -sinensal (5.82 %), β -sesquiphellandrene (1.99 %) and τ -cadinene (1.44 %). The essential oil obtained by hydrodistillation of *A. conyzoides* aerial parts from S. Tomé and Príncipe was characterized by the presence of high percentages of precocene I (34.4 %) and β -caryophyllene (24.6 %), as well as small amounts of precocene II (Martins et al. 2005). *Ageratum conyzoides* essential oil was found to contain precocene II (46.35 %), precocene I (42.78 %), coumarin (5.01 %) and *trans*-caryophyllene (3.02 %) as its major components (Nogueira et al. 2010). Chemical constituents of the essential oil of *A. conyzoides* leaves contained precocene I 74.30 %, (*E*)-caryophyllene 14.23 %, γ -muurolene 3.44 %, bicyclogermacrene 3.14 %, α -humulene 2.80 %, β -cubebene 0.62 %, germacrene D 0.59 %, β -elemene 0.42 %, α -pinene 0.30 % and α -thujene 0.16 % (de Melo et al. 2011).

The main components of the volatiles from the hairy root cultures of *A. conyzoides* were β -farnesene, precocene I, and β -caryophyllene, in different amounts, depending on light conditions and also on the age of cultures (Abdelkadera and George 2011). Precocene I, β -farnesene, precocene II and β -caryophyllene were the main constituents of the volatile oils from the parent plant roots, whereas precocene I, germacrene D, β -caryophyllene and precocene II were the main constituents of the aerial parts of the parent plant.

From the ethanol extract of the whole plant of *Ageratum conyzoides*, a new chromene, 2,2-dimethylchromene 7-methoxy-6-*O*- β -D-glucopyranoside (1), was isolated, together with 13 known compounds, seven of which were being reported for the first time (Adebayo et al. 2011). These were eugenyl-*O*- β -D-glucopyranoside (2), eugenyl-*O*- β -D-apiofuranosyl-(1'' \rightarrow 6')- β -D-glucopyranoside (3), 3-(2'-*O*- β -D-glucopyranosyl)-phenyl-2-*trans*-propenoic acid (4), (2*S*)-2,3-*O*-di-(9,12,15-octadecatrienoyl)-glyceryl-6-*O*-(α -D-galactopyranosyl)-(1'' \rightarrow 6')- β -D-galactopyranoside (5), ((9*Z*,12*Z*,15*Z*)-octadeca-9,12,15-trienoic acid) (6), 7,3',5'-tri-*O*-methyltricitin (7), and cirsilineol (8). The other known compounds isolated were precocene II (9), precocene I (10), 6-(1-methoxyethyl)-7-methoxy-2,2-dimethylchromene (11), 2,2-dimethylchromene-7-*O*- β -D-glucopyranoside (12), 3,5,7,4'-tetrahydroxyflavone (13) and 5,6,7,3',4',5'-hexamethoxyflavone (14).

Classes of Phytochemicals

Monoterpenes, Triterpenes, Sesquiterpenes and Phenylpropanoids

Friedelin, a triterpenoid (Hui and Lee 1971); α -pinene, ocimene, eugenol, methyl eugenol, δ -cadinene were reported from whole plant (Rao and Nigam 1973); caryophyllene oxide from aerial plant parts (González et al. 1991b); β -caryophyllene, the major compound and a large number of minor terpenoids from plant essential oil (Vera 1993); β -caryophyllene (14.35 % in flower essential oil, 17 % in leaf and stem essential oil) (Riaz et al. 1995); camphene,

cubebene, elemene, farnesol, β -farnesene, β -myrcene, β -pinene, α -pinene, β -selinene, α -terpinene, β -caryophyllene from aerial plant parts (Dung et al. 1996); β -caryophyllene (10.5 %) from leaf essential oil (Chalchat et al. 1997); sabinene, β -pinene, α -pinene, β -phellandrene, 1,8-cineole, limonene, terpinen-4-ol, α -terpineol, β -caryophyllene, caryophyllene epoxide, sesquiphellandrene from leaf essential oil (Ekundayo et al. 1988); β -caryophyllene, γ -bisabolene from leaf essential oil (Kong et al. 1999); β -caryophyllene (8 %) from leaf essential oil (Nébié et al. 2004).

Chromene, Chromone, Chromanone and Benzofuran

A solid obtained in the dimerization of ageratochromene (6,7-dimethoxy-2,2-dimethyl-1-benzopyran) (II) in the presence of acid was shown to be 5,6,6a,6b,7,12b-hexahydro-1,2,10,11-tetramethoxy-5,5,7,7-tetramethylcyclopenta [1,2-*c*;5,4,3-*d'**e'*]bis[1]benzopyran (IV) (Kasturi et al. 1973a). 6-demethoxyageratochromene, ageratochromene dimer and 6,7,6',7'-tetramethyl-3'(4')-dehydro-3'-4S-bichroman were isolated from the plant (Kasturi and Manithomas 1967; Kasturi et al. 1973b). Precocene I and II (Vyas and Mulchandani 1980; Quijano et al. 1982); a highly oxygenated chromone, conyzorigun (Vyas and Mulchandani 1984); two chromones 6-acetyl-2,2-dimethyl-3,4-dihydro-chromene and its 7-methoxyderivative were identified from the leaf essential oil (Ekundayo et al. 1988); chromenes, precocene I and II, dihydrodesmethoxyencecalin, desmethoxyencecalin, 6-vinyl-7-methoxy-2,2-dimethylchromene, desmethylenecalin, dihydroencecalin and encecalin were also isolated and identified (Ekundayo et al. 1987); 6-vinyl-7-methoxy-2,2-dimethylchromene; 6-(1-methoxyethyl)-7-methoxy-2,2-dimethylchromene; 6-(1-hydroxyethyl)-7-methoxy-2,2-dimethylchromene; 6-(1-ethoxyethyl)-7-methoxy-2,2-dimethylchromene; 6-angeloyloxy-7-methoxy-2,2-dimethylchromene; encecalin, encecanescin from aerial parts (González et al. 1991a). Besides precocene I (7-methoxyageratochromene), precocene II (ageratochromene), an isodihydroeuparin derivative 2-(2'-methylethyl)-5,6-dimethoxybenzofuran; a chromene 2-(1'-oxo-

2'-methylpropyl)-2-methyl-6,7-dimethoxy-chromene; a chromone 3-(2'-methylpropyl)-2-methyl-6,8-dimethoxy-chrom-4-one and a chromanone 2-(2'-methylprop-2'-enyl)-2-methyl-6,7-dimethoxy-chroman-4-one were identified from *A. conyzoides* essential oil (Pari et al. 1998). The chromenes precocene I and precocene II were identified from leaf oil (Kong et al. 1999) from aerial parts (Dung et al. 1996) and from leaf essential oil (Nébié et al. 2004). A chromene glucoside, 2,2-dimethylchromene 7-*O*- β -glucopyranoside, and a benzofuran derivative 14-hydroxy-2H β ,3-dihydroeuparine from the aerial parts were identified (Ahmad et al. 1999). Precocene I (7-methoxy-2,2-dimethylchromene) and precocene II (6,7-methoxy-2,2-dimethylchromene) (20 mg/ml) were extracted from *A. conyzoides* (Sharma and Sharma 2001). Two chromenes, 6-(1'-hydroxyethyl)-2,2-dimethyl chromene and 7-hydroxyl-2,2-dimethylchromene, were reported as constituents of *A. conyzoides* leaf essential oil (Kasali et al. 2002).

The major constituents of the essential oil of different plant parts of *Ageratum conyzoides*, namely, flowers, stems, leaves and roots, were 6-demethoxyageratochromene (precocene I: 13.2–44.3 %) and ageratochromene (precocene II : 41.1–62.2 %) (Singh et al. 2003). Total chromene was found maximum in leaves (91.7 %) and minimum in roots. The chromene derivative encecalol methyl ether and chromene ester encecalol angelate from the dichloromethane extract of *Ageratum conyzoides* (Harel et al. 2011).

Flavonoids

The following flavonoids were isolated from the leaves: kaempferol-3,7-diglucopyranoside (Nair et al. 1977); from the whole plant a flavone 5,6,7,8,3',4',5'-heptamethoxyflavone and 5'-methoxynobiletin (Adesogan and Okunade 1979); quercetin, quercetin-3-rhamnopyranoside, kaempferol, kaempferol-3-rhamnopyranoside, kaempferol-3,7-diglucopyranoside (Gill et al. 1978); eupalestin (Vyas and Mulchandani 1984); twelve polyoxygenated flavones were isolated from *Ageratum conyzoides*, ageconyflavone A (5,6,7-trimethoxy-3',4'-methylenedioxyflavone), ageconyflavone B (5,6,7,3'-tetramethoxy-4'-hydroxyflavone) and ageconyflavone C

(5,6,7,3',5'-pentamethoxy-4'-hydroxyflavone) (Vyas and Mulchandani 1986). The other nine compounds were identified as linderoflavone B, eupalestin; nobiletin; 5'-methoxynobiletin; 5,6,7,5'-tetramethoxy-3',4'-methylenedioxyflavone; sinensetin; 5,6,7,3',4',5'-hexamethoxyflavone; 5,6,7,8,3'-pentamethoxy-4'-hydroxyflavone; and 5,6,7,8,3',5'-hexamethoxy-4'-hydroxyflavone. Two flavonoids, eupalestin and lucidin dimethyl ether, were isolated from the petroleum ether extract of the plant (Calle et al. 1990). Eupalestin; sinensetin; nobiletin; 5'-methoxynobiletin; 5,6,8,3',4',5'-hexamethoxyflavone; 5,6,7,3',4',5'-hexamethoxyflavone; and 5,6,7,5'-tetramethoxy-3',4'-methylene dioxyflavone were isolated from aerial parts (González et al. 1991b). A flavone 5,6,7,3',4',5'-hexamethoxyflavone (Horie et al. 1993) and another flavone, isolated from *Ageratum conyzoides*, were correctly identified as 8-hydroxy-5,6,7,3',4',5'-hexamethoxyflavone (Horie et al. 1995). An isoflavone glycoside 5,7,2',4'-tetrahydroxy-6,3'-di-(3,3-dimethylallyl)-isoflavone-5-O- α -L-rhamnopyranosyl-(1 \rightarrow 4)- α -L-rhamnopyranoside was isolated from the stem (Yadara and Kumar 1999). Three flavones, 5,6,7,8,3',4',5'-heptamethoxyflavone, 5,6,7,3',4',5'-hexamethoxyflavone, 5,6,8,3',4',5'-hexamethoxyflavone, ageratochromene and its two dimers were isolated and identified from the *A. conyzoides* (Hu et al. 2002; Kong et al. 2004). The major constituents of *Ageratum conyzoides* fresh leaves and its essential oil were demethoxy-ageratochromene, β -caryophyllene, α -bisabolene and *E*- β -farnesene (Kong et al. 2005). 5,6,7,8,3',4',5'-heptamethoxyflavone, 5,6,7,8,3'-pentamethoxy-4', 5'-methylenedioxyflavone were isolated from the hexane plant extract (Moreira et al. 2007) and methoxylated flavonoids were isolated from the dichloromethane plant extract (Harel et al. 2011).

Alkaloids

Open chain pyrrolizidine alkaloids, namely, 9-angeloylretronecine, lycopsamine and echinatine, were identified from the plant (Röder et al. 1990; Wiedenfeld and Röder 1991). Trigo et al. (1988) found several alkaloids in the plant, including 1,2-desifropyrrolizidinine and lycopsamine which could have hepatotoxic activity.

Sterols

β -Sitosterol, Δ^{22} stigmasterol, Δ^{22} brassicasterol, dihydrobrassicasterol, Δ^{22} spinasterol, dihydrospinasterol were isolated from the plant (Hui and Lee 1971; Horng et al. 1976; Dubey et al. 1989; González et al. 1991b).

Phenolic and Miscellaneous Compounds

Fumaric and caffeic acid (Nair et al. 1977); three coumarinic compounds including 1-2 benzopyrone (Ladeira et al. 1987); (+)-sesamin (González et al. 1991b); a coumarin and phytol (a diterpene alcohol) were isolated from essential oil of the plant (Vera 1993); aurantiamide acetate (Sur et al. 1997); 3,3-dimethyl-5-*tert*-butylindone, and fenchyl acetate from leaf oil (Kong et al. 1999); an unsaturated branched chain fatty acid, (Z)-6-methyl-12-heptadecenoic acid (Pari et al. 2000); coumarin from the plant (Moreira et al. 2007); 2*H*-1-benzopyran-2-one (coumarin) from leaves (Alcantara 1985) and coumarin from leaves (Widodo et al. 2008). Xuan et al. (2004) identified three phenolic compounds: gallic acid, coumaric acid and protocatechuic acid in the leaves, stem and roots, and catechin was found only in the stem while *p*-hydroxybenzoic acid was detected in both the leaves and stem. Three additional putative allelochemicals were found in the leaves consisting of *p*-coumaric acid, sinapic acid and benzoic acid. The methylene chloride extract of the air-dried aerial parts of *Ageratum conyzoides* afforded a new natural compound, pyrrolone, 5-ethoxy-1*H*-pyrrol-2(5*H*)-one, together with a known flavonoid (Hussien et al. 2010).

Antioxidant Activity

Extracts of *A. conyzoides* were found to have radical scavenging activity (Adebayo et al. 2010). The water, *n*-butanol and ethyl acetate extract elicited DPPH scavenging activity of 87.80, 85.40, 72.56 and 60.87 %, respectively, while the petroleum ether extract had a low activity of 7.84 %. Kaempferol isolated from the ethyl acetate extract of *A. conyzoides* rapidly scavenged DPPH with an EC₅₀ value of 130.07 g/kg highly comparable to the standard

control (vitamin C) with an EC_{50} value of 127.13 \pm 8.56 g/kg. Methanol extract of *A. conyzoides* showed the highest antioxidant activity in FRAP and DPPH assay, whereas *A. conyzoides* essential oil showed greater lipid peroxidation inhibition than methanol extract (Patil et al. 2010).

Wound Healing Activity

Methanol extracts of *Ageratum conyzoides* were found to have a better wound healing enhancing action compared with normal saline-treated controls (Oladejo et al. 2003a). Skin wounds of Wistar rats dressed with the extract showed a significant increase in the percentage wound contraction (82.3 %) at day 10 compared with the saline-treated control (55 %). Oladejo et al. (2003b) also reported that on the tenth day post-wound creation in Wistar rats, *Ageratum*-treated skin sections showed fewer inflammatory cells compared with similar honey and control skin sections. Honey and *Ageratum* caused significant greater wound contraction than controls. Healed wounds from the *Ageratum* group had significantly fewer fibroblasts than honey and controls. Dash and Murthy (2011) reported that rats treated with methanol and aqueous leaf extracts of *A. conyzoides* showed faster rate of wound healing compared to other extracts under study. The chloroform extract also produced promising results but the effects were seen to be of lesser magnitude. The petroleum ether extract did not produce significant results. The results supported the use of the leaves of *A. conyzoides* for wound healing activity in folkloric medicine. Topical application of *A. conyzoides* ethanol extract was found to accelerate the rate of wound healing in rats (Arulprakash et al. 2012). The extract increased cellular proliferation and collagen synthesis. Wounds treated with the extract were found to heal much faster, based on the improved rates of epithelialization and wound contraction and on the histopathological results. A 40 % increase in the tensile strength of the treated tissue was observed.

Anticancer Activity

The aqueous root extract of the aqueous extract exhibited antitumour activity against murine ascites Dalton's lymphoma in vivo (Rosangkima and Prasad 2004). Glutathione in the liver and Dalton's lymphoma cells of treated tumour-bearing mice was found to be decreased. The methanol fraction from the ethyl acetate extract of *A. conyzoides* leaves was found to inhibit in-vitro growth of Ehrlich tumour (Momesso et al. 2009).

From the preliminary anticancer screening, the petroleum ether extract of *A. conyzoides* exhibited a significant in-vitro inhibition on human gastric carcinoma (SGC-7901), human colon adenocarcinoma (HT-29), and mouse leukaemia (P-388) cancer cell lines (Adebayo et al. 2010). Similarly, the ethyl acetate extract showed a significant in-vitro inhibition on human non-small cell lung carcinoma (A-549), SGC-7901, HT-29, P-388, human breast carcinoma (MDA-MB-231) and human prostate carcinoma (DU-145) cancer cell lines, while the ethanol extract had a significant inhibitory activity on HT-29 and P-388 cancer cell lines. The results showed that ethyl acetate extract of *A. conyzoides* exhibited the highest cytotoxic activity on human non-small cell lung carcinoma (A-549) and mouse leukaemia (P-388) with IC_{50} values of 0.68 and 0.0003 μ g/ml, respectively. The *n*-butanol and water extracts showed no significant inhibition on any of the cancer cell lines. Tri-*O*-methyltricetin(7), precocene II(9), 3,5,7,4'-tetrahydroxyflavone (13) and 5,6,7,3',4',5'-hexamethoxyflavone (14) isolated from the ethanol extract of the whole plant exhibited inhibitory activity on the mouse leukaemia P-388 cancer cell line with IC_{50} values of 12.8, 24.8, 3.5 and 7.8 μ M, respectively, while compound 9 exhibited inhibitory activity on the human colon adenocarcinoma HT-29 cancer cell line with an IC_{50} value of 61 μ M; the others showed no significant cytotoxic activity on the cell lines tested time (Adebayo et al. 2011).

All the fractions of *A. conyzoides* leaf ethanol extract and the petroleum ether fraction of *Parkia biglobosa* were cytotoxic to human lung cancer (SK-MES 1) cell lines which to some extent may support their traditional inclusion in herbal

preparations for treatment of cancer (Adetutu et al. 2012).

Antimicrobial Activity

The ether and chloroform extracts of *A. conyzoides* used in wound healing therapy inhibited in-vitro growth of *Staphylococcus aureus* (Durodola 1977). The methanol extract of the whole plant inhibited growth of *Staphylococcus aureus*, *Bacillus subtilis*, *Escherichia coli* and *Pseudomonas aeruginosa* (Al-Magboul et al. 1985). The aqueous leaf extract was found to be inhibitory to ringworm pathogens *Epidermophyton floccosum* and *Trichophyton mentagrophytes* (Mishra et al. 1991). *Ageratum conyzoides* ethanol extract exhibited antifungal activity against *Epidermophyton floccosum* with minimum inhibitory concentration of less than 10 mg/ml (Sukandar et al. 1992). The ethanol leaf extract was found to inhibit growth of *Escherichia coli*, *Microsporum canis* and *Trichophyton mentagrophytes* (Vlietinck et al. 1995). *Ageratum conyzoides* essential oil exhibited in-vitro antibacterial activity against 20 bacteria and inhibited in-vitro growth of four fungi *Candida albicans*, *Cryptococcus neoformans*, *Sclerotium rolfsii* and *Trichophyton mentagrophytes* (Pattnaik et al. 1996). The ethanol plant extract inhibited growth of *Streptococcus pyogenes* and *Neisseria gonorrhoeae* (Geyid et al. 2005).

Among 16 tested plants, *Cleome gynandropsis* and *Ageratum conyzoides* aqueous extracts exhibited a significant control of the growth of *Alcaligenes viscolactis*, *Klebsiella aerogenes*, *Bacillus cereus* and *Streptococcus pyogenes* (Perumal Samy et al. 1999). The essential oil of *A. conyzoides* aerial parts showed weak activity against *Staphylococcus aureus*, *S. epidermidis*, *Streptococcus faecalis*, *Proteus vulgaris* and *Cladosporium cladosporioides* and was inactive against *Escherichia coli*, *Candida albicans*, *Cryptococcus neoformans*, *Aspergillus niger* and *A. fumigatus* (Martins et al. 2005). Of all the leaf extracts, *n*-hexane, acidic ethyl acetate, basic ethyl acetate and ethanol, the basic ethyl acetate extract showed the highest antibacterial

activity when tested against *Staphylococcus aeruginosa*, *Staphylococcus aureus*, *Staphylococcus epidermidis* and *Streptococcus haemolyticus* (Wirahardja et al. 2001). Phytochemical analysis showed the presence of alkaloids, flavonoids, polyphenols, saponins, quinines and tannins in the *A. conyzoides* (babadotan) leaves.

A coumarin compound isolated from acetone fraction of *A. conyzoides* leaves exhibited antifungal activity against *Aspergillus niger* with MIC value of 62.5 µg/ml (Widodo et al. 2008). Of ten methanol plant extracts, *A. conyzoides*, *Scleria striatinix* and *Lycopodium cernuum* showed very potent antibacterial activity against *Helicobacter pylori* (Ndip et al. 2007). The lowest MIC for *A. conyzoides* ranged from 0.063 to 1.0 mg/ml and MBC ranged from 0.098 to 12.5 mg/ml. All extracts of the leaf, stem and root of *A. conyzoides* inhibited the growth of the bacterial isolates *Staphylococcus aureus*, *Yersinia enterocolitica*, *Salmonella gallinarum* and *Escherichia coli* in a concentration dependent manner (Okwori et al. 2007). The hexane extract of the leaf, stem and root elicited 100 % susceptibility; the aqueous leaf extract gave 75 % susceptibility, while methanolic leaf extract gave 50 %. The MIC(s) ranged from 6.25 to 100 mg/ml while the MBC(s) gave a range of 3.13 to 50 mg/ml. Phytochemical analysis of the dried leaves revealed the presence of resins, alkaloids, tannins, glycosides and flavonoids. The dried stems revealed the presence of resins saponins, tannins, glycosides and flavonoids, while the dried roots contained resins, alkaloids saponins and flavonoids.

The growth and aflatoxin production of the toxigenic strain *Aspergillus parasiticus* was completely inhibited by *A. conyzoides* essential oil (Patil et al. 2010). All the studied concentrations of the oil caused a reduction in mycelia growth and decreased aflatoxin production. Volatiles from macerated green leaf tissue of *A. conyzoides* were also effective against *Aspergillus parasiticus*. The strongest antibacterial activity was observed against the bacteria *Staphylococcus aureus* and *Bacillus subtilis*. *Ageratum conyzoides* essential oil inhibited *Aspergillus flavus* growth to different extents depending on the

concentration and completely inhibited aflatoxin production at concentrations above 0.10 µg/ml (Nogueira et al. 2010). Ultrastructural changes were more evident in the endomembrane system, affecting mainly the mitochondria of the fungal cells. Degradation was also observed in both surrounding fibrils. In-vitro studies showed that the ethanol extracts of *Parkia biglobosa* and *A. conyzoides* were inhibitory to *Escherichia coli*, *Staphylococcus aureus*, and methicillin-resistant *Staphylococcus aureus* (MRSA) but not to *Pseudomonas aeruginosa* (Adetutu et al. 2012).

Haematopoietic/Haemostatic Activities

The ethanol leaf extract of *Ageratum conyzoides* administered by gavage to rats was found to increase in a dose-related fashion packed cell volume (PCV) and haemoglobin at the doses of 200, 400 and 500 mg/kg, RBC (red blood corpuscle) for 400 and 500 mg/kg and marginal increases that were not significant for 200 mg/kg (Ita et al. 2007). MCH (mean corpuscle haemoglobin) and MCV (mean corpuscle volume) for 200, 400 and 500 mg/kg doses were not significant. White blood corpuscle (WBC) recorded marginal increases that were not significant. Marginal but nonsignificant decreases in body weight were also observed. The authors concluded that the results indicated haematopoietic potentials of the extract and that it could possibly remedy anaemia. The methanol leaf extract of *A. conyzoides* significantly decreased the bleeding time, prothrombin time and clotting time, respectively, in a dose-dependent manner in albino rats (Bamidele et al. 2010). Conversely, plasma fibrinogen concentration significantly increased. The study suggested the methanol leaf extract of *A. conyzoides* to possess haemostatic activity.

Hypoglycaemic Activity

In streptozotocin-diabetic rats, oral administration of the aqueous leaf extract of *Ageratum conyzoides* elicited a significant reduction of

blood glucose level of 9.5 % after 1 hour and 21.3 % after 4 hours (Nyunai et al. 2006). The aqueous leaf extracts of *A. conyzoides* at 200 and 300 mg/kg showed statistically significant hypoglycaemic and antihyperglycaemic activities in streptozotocin-induced diabetic rats (Nyunai et al. 2009b). For the oral glucose tolerance test, 100 mg/kg dose only attenuated significantly the rise of blood glucose in normal fasted rats, thus confirming the hypoglycaemic properties of the leaves of *Ageratum conyzoides*. The results validate its use for diabetes in folk medicine. Aqueous leaf extract of *A. conyzoides* had a positive effect on the oxidation-reduction system on streptozotocin-induced diabetic rats and improved glycaemia of diabetic rats (Nyunai et al. 2009a). The extract lowered lipid hydroperoxides in the groups treated with 100 and 200 mg/kg when compared to the negative control group. Antioxidant power (FRAP) was also higher in the 100 mg/kg group. Further, glycaemia was decreased in the group receiving 200 and 300 mg/kg of the extract.

Gastroprotective Activity

The ethanol extract of *Ageratum conyzoides* was found to have gastroprotective activity (Shirwaikar et al. 2003). Oral administration of the ethanol extract at dose levels of 500 and 750 mg/kg significantly protected gastric lesions by 80.59 and 89.33 %, respectively, as compared to misoprostol (74.43 %) in the ibuprofen model; by 97.09 and 99.24 %, respectively, in the cold stress model as compared to famotidine (77.86 and 92.71 %); and by 86.58 and 92.29 %, respectively, in the alcohol model. The findings suggested that the significant gastroprotective activity could be mediated by its antioxidant activity, Ca²⁺ channel blocking and antiserotogenic properties.

Radioprotective Activity

Administration of alcoholic plant extract of *Ageratum conyzoides* resulted in a dose-

dependent decline in radiation-induced mortality up to a dose of 75 mg/kg, the dose at which the highest number of survivors (70.83 %) was observed (Jagetia et al. 2003). In further studies pretreatment of mice with 75 mg/kg extract reduced the severity of symptoms of radiation sickness and mortality at all exposure doses, that is, 6, 7, 8, 9, 10 and 11 Gy of gamma radiation, and a significant increase in survival was observed compared with the untreated irradiated group. The radioprotection afforded by *Ageratum* extract may be in part due to the scavenging of reactive oxygen species induced by ionizing radiation.

Antiinflammatory Activity

Ageratum conyzoides was found to have fairly good antiphlogistic effect in comparison with hydrocortison, as well as inhibiting action on experimental mice tumour development (Nguyen and Pham 1973). Essential oils from violet and white flower varieties have the same qualitative composition but differ in content of each essential oil type. Treatment of rats with the water-soluble fraction (WSF) obtained from a hydroalcoholic extract of *A. conyzoides* was found to reduce articular incapacitation induced by carrageenan (300 µg) (Magalhães et al. 1997). The neutrophil migration induced by carrageenan (300 µg) injection into rat peritoneal cavities and into 6-day-old subcutaneous air pouches was significantly inhibited by WSF pretreatment (30 and 50 mg/kg; s.c.). At the same dose WSF also inhibited the carrageenan (400 µg/paw)-induced oedema but failed to modify the oedema induced by dextran (100 µg/paw). Additionally, the increase in the cutaneous vascular permeability induced by the potent leucocyte chemotactic agent LTB₄ (39 ng co-injected with 500 ng iloprost, i.d.) was significantly blocked by WSF (30 mg/kg; i.p.). The results suggested that WSF could inhibit the inflammatory reactions induced by neutrophil mobilizing stimuli. The results of another study showed that rats treated with hydroalcoholic

extract of *Ageratum conyzoides* leaves (250 mg/kg body weight; p.o.) had a 38.7 % reduction in cotton-pellet granuloma (Moura et al. 2005). The development of chronically induced paw oedema was also reduced significantly by the plant extract. The toxicity study did not show any treatment-related abnormalities in biochemical and hematological parameters. The biochemical analysis from blood samples drawn from group of rats treated orally with 500 mg/kg body weight did, however, present 30.2 % reduction of serum glutamic pyruvic transaminase activity as compared to the corresponding control group. Their results confirmed the antiinflammatory properties of *A. conyzoides*, with no apparent hepatotoxicity. In another study, *A. conyzoides* and *Emilia sonchifolia* alcoholic extracts inhibited 49.85 and 39.47 % of acetic acid-induced pain at the highest dose 2.0 g/kg body weight (BW) in Swiss albino mice (Rahman et al. 2012). These effects were statistically significant as compared to the reference drug, diclofenac sodium (40 mg/kg). *A. conyzoides* reduced 35.48 % and *Emilia sonchifolia* reduced 38.70 % of formalin-induced pain by 2.0 g/kg which were also statistically significant as compared to morphine (0.5 mg/kg). In a time-dependent inhibition of carrageenan-induced paw oedema model in Wistar albino rats, the extracts of *A. conyzoides* and *E. sonchifolia* elicited 50.23 and 48.11 % inhibition of paw oedema at the 4th hour of administration, respectively, and the effects were statistically significant.

Contradictory results were obtained by Yamamoto et al. (1991) in Brazil who found that oral treatment of rodents (rats and mice) with water extract of *A. conyzoides* neither reduced the inflammatory oedema induced by carrageenan or dextran, nor did it reduce the chronic paw oedema induced by complete Freund's adjuvant or formaldehyde in rats. Also the extract did not decrease the reaction to pain stimuli as evaluated by tail flick response in immersion test and writhings induced by 0.8 % acetic acid. In isolated guinea pig ilea, the extract presented an unexpected histamine-like activity characteristic of a partial agonist.

Electrocardiographic Activity

Ageratum conyzoides leaf extract changed the electrocardiogram, atrial impulse velocity, and coronary vessels resistance on isolated guinea pig heart (Garcia and Carvalho 1999). Electrocardiographic alterations were (a) PR interval increased from 80 to 105 ms, (b) QT interval decreased from 170 to 154, (c) heart rate decreased from 170 to 152 bpm, (d) atrial impulse velocity decreased from 51 to 45 cm/s, and (e) the time spent for the impulse to be conducted from the atrium to the His bundle increased from 73 to 100 ms. These effects disappeared after a washout.

Analgesic Activity

The raw leaf juice extract of *A. conyzoides*, injected intraperitoneally at doses of 50 and 100 mg/kg, caused a precocious ataxia, a sedation and a slight ptosis in Wistar rats (Abena et al. 1993). Six hours after injection, those effects disappeared: a reduction of spontaneous motor activity. *Ageratum conyzoides* was one of several plant species found to be a source of potential analgesic compounds when tested in three in-vitro radioligand binding assays (Sampson et al. 2000). The three neuropeptide receptors chosen were bradykinin (BK II), expressed in Chinese hamster ovary cells (CHO), neurokinin 1 (NK 1) expressed in astrocytoma cells and calcitonin gene-related peptide (CGRP) which were all implicated in the mediation of acute pain in the mammalian central nervous system.

Spasmolytic/Anticonvulsant Activities

Ageratum conyzoides root and aerial part extracts were found to induce relaxation on isolated trachea and isolated rat uterus (Achola and Munenge 1998). There was no significant difference between the activities of root and aerial part extracts. The extracts extract inhibited uterine contractions induced by 5-hydroxytryptamine, suggesting that the plant extract exhibited specific antiserotonergic activity on

isolated uterus. However, the uterine contraction caused by acetylcholine was unaffected by the plant extract.

Results of another study in isolated rat uterus and intestinal smooth muscles supported the popular use of *A. conyzoides* as a spasmolytic (Silva et al. 2000). The water-soluble fraction of *Ageratum conyzoides* (0.2 and 0.4 mg/ml) increased EC_{50} values and decreased maximum responses to acetylcholine and calcium chloride and at 0.5–3.3 mg/ml also produced direct myorelaxant effect on smooth muscle preparations. Theophylline potentiated the relaxant action of the plant water fraction and also prevented the decrease in maximum response promoted by the fraction in acetylcholine concentration-effect curves. The results appeared to be partially linked to calcium mobilization and also suggest that the water-soluble fraction could act synergistically with theophylline in the inhibition of cyclic AMP phosphodiesterase.

In the maximal electroshock (MES) model, pretreatment with methanol (90 %) extract of *Ageratum conyzoides* exhibited significant reduction in duration of hind-leg extension with 200 mg/kg dose, and the effect was dramatically reduced with 400 mg/kg (Varadharajan and Rajalingam 2011). Similar dose-dependent results were obtained in pentylenetetrazole-induced seizure model in albino Wistar rats by delayed onset of clonic convulsions. The complete protective effect against mortality was reported in both the tests. Acute toxicity of extract was nontoxic up to the recommended dose 2,000 mg/kg body weight orally as per OECD guidelines No. 423.

Hepatoprotective Activity

Studies showed that ethanol leaf extract of *Ageratum conyzoides* afforded protection against acetaminophen and caffeinated acetaminophen hepatotoxicity in rats (Ita et al. 2009). Rats treated with acetaminophen plus caffeine plus leaf extract (250 or 500 mg/kg) had significant reductions in the serum aspartate aminotransferase,

alanine aminotransferase and alkaline phosphate levels compared to the elevated levels in rats treated with only acetaminophen or caffeine or both. Total serum protein was marginally increased in the group treated with acetaminophen plus caffeine plus 250 mg/kg extract and significantly increased in the group treated with acetaminophen plus caffeine plus 500 mg/kg extract.

Diuretic Activity

A. conyzoides leaf water extract exhibited significant diuretic activity in albino Wistar rats (Falang et al. 2012). At the end of 24 hours, 200, 400 and 600 mg/kg of extract produced 7.60, 7.00 and 6.80 ml of urine, respectively. The pH of urine produced by the extract and standard drugs were all alkaline. At a dose of 600 mg/kg body weight, there was significant increase in concentrations of sodium, potassium and chloride ions. This could be important in the treatment of cardiovascular diseases such as hypertension. The results suggested that the leaf extract of *A. conyzoides* had diuretic properties similar to acetazolamide.

Antiprotozoal Activity

The dichloromethane extract prepared from aerial parts of *Ageratum conyzoides* was found to exhibit significant activity ($IC_{50}=0.78\text{ }\mu\text{g/ml}$) against bloodstream forms of *Trypanosoma brucei rhodesiense*, the etiologic agent of East African human trypanosomiasis (East African sleeping sickness) (Nour et al. 2010). This extract also exhibited appreciable activities against *Leishmania donovani* (Kala-Azar, $IC_{50}=3.4\text{ }\mu\text{g/ml}$) as well as *Plasmodium falciparum* (Malaria tropica, $IC_{50}=8.0\text{ }\mu\text{g/ml}$). Five highly methoxylated flavonoids along with the chromene derivative enecalol methyl ether were isolated. While the chromene turned out to be inactive against the tested parasites, the flavonoids showed activity against the protozoan pathogens, some in the lower micromolar range. However, none of these isolated compounds was as active as the crude

extract. *Ageratum conyzoides* plant extract was found to have antiplasmodial activity against chloroquine-resistant *Plasmodium falciparum*, causal agent of malarial (Madureira et al. 2002). The aqueous leaf extract of *A. conyzoides* exhibited significant and dose-dependent antiplasmodial activity against *Plasmodium berghei* in mice (Ukwe et al. 2010). All the fractions from the methanol extract showed significant but varying levels of antiplasmodial activity. The LD_{50} was estimated to be greater than 5,000 mg/kg, p.o in mice. Phytochemical screening of the extracts revealed the presence of alkaloids, glycosides, flavonoids, saponins, tannins, reducing sugar, proteins, carbohydrates and resins. The aqueous leaf extract of *A. conyzoides* exhibited significant and dose-dependent antiplasmodial activity against *Plasmodium berghei* in mice (Ukwe et al. 2010). All the fractions from the methanol extract showed significant but varying levels of antiplasmodial activity. The LD_{50} was estimated to be greater than 5,000 mg/kg, p.o in mice. The dichloromethane extract of *Ageratum conyzoides* was recently shown to exhibit considerable activity against *Trypanosoma brucei rhodesiense* (Harel et al. 2011). Isolated compounds, namely, methoxylated flavonoids as well as the chromene derivative enecalol methyl ether were less active than the crude extract. The activity of the extract was found to decrease considerably while stored in solution. The unstable chromene ester enecalol angelate was identified as native constituent of the dichloromethane extract of *Ageratum conyzoides*. Its activity against *Trypanosoma*, *Leishmania* and *Plasmodium* species was quite low, so that it does not represent the chemical principle responsible for the high antiprotozoal activity of the crude extract.

Schistosomicidal Activity

The essential oil of *Ageratum conyzoides* was reported to have schistosomicidal effects in vitro against adult worms of *Schistosoma mansoni* (de Melo et al. 2011). The essential oil was less effective than the positive control (praziquantel) in terms of separation of coupled pairs, mortality,

decrease in motor activity and tegumental alterations. However, the essential oil caused an interesting dose-dependent reduction in the number of eggs of *S. mansoni*. Precocene I (74.30 %) and (*E*)-caryophyllene (14.23 %) were identified as the two major constituents of the essential oil; both compounds were found to be much less effective than the essential oil and praziquantel.

Anticoccidiosis Activity

Studies showed that administration of *Ageratum conyzoides* extract in the drinking fluid to broilers infected with oocysts of *Eimeria tenella*, was efficacious in treating caecal coccidiosis (Nweze and Obiwulu 2009). The faecal oocyst per gram of faeces decreased steadily in all the treatment groups until it became zero. The packed cell volumes, weight and red blood cell counts of the treated birds were significantly higher than those of the infected untreated control. No signs of toxicity were observed during the acute toxicity test. The results confirmed its ethnoveterinary use in the treatment of coccidiosis. *Ageratum conyzoides* leaf extracts were found to have anticoccidial activity in chicken (2012). Pertinent coccidia populations reductions were as follows: 10% water-pulverized leaf extract 96 % ($n=3,388$), 10 % whole leaf extract 81.7 % ($n=1,500$), Coxisol 97 % ($n=1,216$) and Amprocox 85.9 % ($n=1,600$), the last two being commercial coccidiostats. Pathohistological investigation of treatment with 10 % whole extract of *Ageratum conyzoides* did not find any lesions in the heart, liver, lungs kidney and spleen.

Insecticidal/Larvicidal Activity

The petroleum ether extract of the whole plant induced morphogenetic abnormalities in the formation of larvae of the mosquitoes *Culex quinquefasciatus*, *Aedes aegypti* and *Anopheles stephensi* (Sujatha et al. 1988). Vyas and Mulchandani (1980) reported the action of chromenes (precocenes I and II), isolated from *Ageratum conyzoides*, which accelerated larval

metamorphosis, resulted in juvenile forms or weak and small adults. Ekundayo et al. (1988) also demonstrated the juvenilizing hormonal action of precocene I and II in insects, the most common effect being precocious metamorphosis, producing sterile or dying adults. Acetone extracts of *Ageratum conyzoides* showed growth inhibitory and juvenile hormone-mimicking activity to the treated larvae of *Culex quinquefasciatus* (Saxena et al. 1992). Larval pupal intermediates, demalanized pupae, defective egg rafts and adult with deformed flight muscles were few noticeable changes. Biting behaviour was observed to be affected by *Ageratum*, and loss of fecundity was observed in the treated mosquitoes but no sterilant effects could be seen. Adults obtained from larvae exposed to the plant extract produced significantly shorter egg rafts than in control. Petroleum ether extract of the flowers was inhibitory to the *Anopheles stephensi* mosquitoes (Kamal and Mehra 1991). The methanol extract of the whole plant suppressed the population of *Anopheles stephensi* at the preimaginal stage (Saxena and Saxena 1992).

Ageratum conyzoides oil showed larvicidal activity against *Aedes aegypti* with LC_{50} value of 148 $\mu\text{g/l}$ (de Mendonça et al. 2005). *A. conyzoides* also induces morphogenetic abnormalities in the formation of mosquito larvae (*Culex quinquefasciatus*, *Aedes aegypti* and *Anopheles stephensi*). This has been verified using petroleum ether extracts (5 and 10 mg/l) of the whole plants. The larvae showed intermediary stages between larvae–pupae and discolored and longer pupae, as well as incompletely developed adults (Sujatha et al. 1988). Extracts of the flowers of this species showed activity against mosquitoes (*Anopheles stephensi*), in the last instar, showing DL 50 with 138 ppm (Kamal and Mehra 1991).

Ageratum conyzoides plant hexane extract was reported to have activity against *Musca domestica* (González et al. 1991a). The petroleum ether extract of *Ageratum conyzoides* exhibited insecticidal activity against *Musca domestica* (Diptera) third instar larvae, and *Cynthia carye* (Lepidoptera) third, fourth and fifth instar larvae and was also active against *Acanthoscelides obtectus* (Coleoptera) adults (Calle et al. 1990).

The known chromene precocene II was isolated from the extract and found to be highly toxic to *M. domestica* third instar larvae under sunlight exposure, while no larvicidal effect was shown under UV irradiation or in dark. Two flavonoids, eupalestin and lucidin dimethyl ether, were also identified in the extract.

Toxicity Studies

The plant has been reported to contain pyrrolizidine alkaloids (Trigo et al. 1988; Röder et al. 1990; Wiedenfeld and Röder 1991) which have been linked to liver and lung cancers and a range of other deleterious effects (Couet et al. 1996). Preliminary study found that rats that consumed a diet of 50 % *A. conyzoides* leaves for 2 weeks or 25 % *A. conyzoides* for 4 weeks appeared to lose weight compared to control rats that were fed with normal cubed diet for rodents (Sani and Stoltz 1993). Histopathological examination revealed extensive liver lesions characterized by megalocytosis and bile duct cells proliferation. Although the analysis of pyrrolizidine alkaloid-like with hot methanol extraction was low (0.014 %), the pathological changes of liver showed that *Ageratum conyzoides* caused pyrrolizidine alkaloid poisoning in rats.

However, results of recent animal studies suggested that ingestion of *Ageratum conyzoides* leaf extract daily for 21 days may not be hepatotoxic at the doses (200 mg/kg body weight, 400 mg/kg body weight and 600 mg/kg body weight of the extract) investigated (Antai et al. 2009). Treatment of rats with the respective doses of the extract did not significantly alter the serum and liver levels of total protein, ALT, AST and ALP in all test groups. Results of acute and sub-chronic (28-day) oral toxicity studies suggested the hydroalcoholic extract of *A. conyzoides* to be relatively safe when administered orally in rats (Diallo et al. 2010). The limit dose of 5,000 mg/kg did not cause any mortality or signs of acute toxicity in the rats tested during the observation period. In the subchronic tests, the results did not show any treatment-related abnormalities in terms of haematological and biochemical param-

eters. However, urea was significantly lower in the group treated with 500 mg/kg of *A. conyzoides* extract. The weekly body and organ weight of the rats showed no significant differences between the control and the rats treated with the extract except for liver where there was a significant increase in rats that received 1,000 mg/kg, that is, 3 g as against 2.5 g for the control.

Traditional Medicinal Uses

Ageratum conyzoides was reported as one of several plant species used for prostate problems in folkloric ethnomedicine in Trinidad and Tobago (Lans 2007). *Ageratum conyzoides* is a plant used in traditional medicine for mental and infection diseases, cephalgia, dyspnea, enteralgia and fever (Abena et al. 1993). *A. conyzoides* leaves were reported to be used externally to heal wounds, cuts, scratches or itches and internally, decoctions of roots are taken for treating coughs by the Temuan tribe in Ulu Langat, Selangor, Malaysia (Ong 1990). Decoctions obtained from boiling whole plant parts were used to treat asthma, while leaves obtained from white-flowered types of this species were used to alleviate toothache. In Peninsular Malaysia, the Malays poultice wounds externally with the leaves, which have been heated and oiled (Burkill 1966). For itch, a poultice of the leaves mixed with those of *Phyllanthus pulcher* or *Justicia* is used. Pounded plant material is applied to the abdomen of children for severe diarrhoea. The plant decoction is used for fever and dysentery. The plant has also been reported to be used for urinary disorders. In Java, the leaves are used as a paste mixed with chalk for wounds and a paste of the roots rubbed on the body for fever (Heyne 1927). Crevost and Petelot (1929) reported that the Annamites apply a poultice of the leaves to the hair.

In Vietnam, *Ageratum conyzoides* is used to treat inflammation of the nose, dropsy, wound pimples, eczema and postpartum haemorrhage and to regulate menses allergic sinusitis (Doan and Nguyen 1979; Dung et al. 1996; Vo 1997). The plant was reported to contain essential oils, phenols (eugenol), carotenoids, phytosterols,

tannins and saponins (Vo 1997). In the Philippines the juice of the fresh leaves is pounded, mixed with salt and used as vulnerary (Stuart 2012). Sometimes the leaves are cooked in coconut oil and the medicated oil is applied to wounds. The boiled decoction of stem, roots and flowers are employed for stomach disorders. The plant decoction is used for cough, colds, fever, skin disease and high blood pressure. The plant is also used for bleeding due to external wounds, furuncle, eczema, carbuncle and as poultices for headaches. Plant juice is dropped into the ear to treat otitis media.

In Gabon, the Masango people eat the leaves with cola fruit and salt to treat pain (Akendengue and Louis 1994); the leaves are used to treat cuts and wound, fever, painful menstruation; leaves cooked in palm oil is taken as remedy for sexually transmitted diseases (Raponda-Walker and Sillans 1995). *A. conyzoides* is used to treat fever, measles, postpartum haemorrhage and snake bites in Benin (Adjanohoun et al. 1989), while in Nigeria it is used for skin diseases, wound healing, diarrhoea and pain associated with navel in children (Okunade 2002). A leaf decoction is used to treat human immunodeficiency virus (HIV)/AIDS in Nigeria (Igoli et al. 2005; Kayode et al. 2009); HIV/AIDS, herpes zoster and cryptococcal meningitis in Tanzania (Kisangau et al. 2007); and anguillulosis in the Republic of Guinea (Keita et al. 1999). In the Republic of Congo, leaves juice/extract/decoction are employed to treat headache, rib pain, intercostal pain, body side pain, asthma and inflammatory disorders like rheumatism and arthritis and macerated whole plant is used for treating dyspnea (Adjanohoun et al. 1988). In the Ivory Coast, the plant is used to treat abdominal pain (Diehl et al. 2004). *Ageratum conyzoides* was used to treat epilepsy by traditional healers in Tanzania (Moshi et al. 2005). In Mauritius and Rodrigues, the leaves are used as a diuretic in urinary diseases (Gurib-Fakim et al. 1993), and in Mauritius, the leaves are used to treat diarrhoea, skin infection and gas in the stomach (Gurib-Fakim et al. 1997). In Kwara State, Central Nigeria, leaves are used for *Candida* body infection and grounded leaves mixed with shea butter as an ointment are used to

massage inflamed painful area in the neck (Bhat et al. 1990).

In an ethnomedicinal survey of plants in the Rivers State of Nigeria, of 188 plant species, the most important and valuable species were found to be *Ageratum conyzoides* and *Tridax procumbens* (Ajibesin et al. 2012). The plants were commonly used for dermal or digestive problems and fever/malaria. The most used plant part was leaves (42 %), while decoction was the main method of drug preparation (36 %). The tribals of Bangangte in Western Cameroon employed the juice from the plant for peptic ulcer (Noumi and Dibakto 2000). In Madagascar, the leaves are used in tea for diarrhoea and the leaf sap is used as a coagulant (Novy 1997). In India and Central Africa, the plant is used to treat wounds and burns (Durodola 1977). In Kenya, the leaf juice is used to treat eye diseases, macerated leaves used as antiseptic for wounds to stop bleeding and haemorrhagic diarrhoea, mycotic skin infection, furuncle, eczema, carbuncle; leaf and root decoctions are used for coughs; and root decoctions used for chest pains (Noumi 2004, Tsabang et al. 2001). In the Republic of Congo (Brazzaville), leaves and roots are used for headache; leaves are employed for intercostal rib pain and side-body pain, asthma and antiinflammatory problems; macerated plant is used for dyspnea (Adjanohoun et al. 1988). In Benin, grounded leaves are used for infectious diarrhoea, fever, malaria and nausea; aerial plant parts are used for giddiness and postpartum haemorrhage (Adjanohoun et al. 1989).

In Northwest Argentina, the plant extract is drunk as a remedy for cough (Hilgert 2001).

In Mexico, the aerial plant part infusion is used in the treatment of diabetes (Andrade-Cetto and Heinrich 2005). *Ageratum conyzoides* has been used in Brazilian folk medicine to treat various ailments such as metrorrhagia, fevers, dermatitis, inflammation, arthritis, rheumatism, diarrhoea and diuretics (Lima et al. 2011). The flowers and leaves are used in the form of an infusion for their analgesic and antiinflammatory properties. In Brazil, the plant is used as an analgesic and antiinflammatory (Elisabetsky and Wannmacher 1993); the leaves are used to treat malaria and yellow fever (Ming 1999); the aerial

parts is used as a tonic, stimulant and emmenagogue (de Melo Junior et al. 2002).

In India, the plant is used to treat leprosy and the essential oil is used as lotion for purulent ophthalmia (Kasturi et al. 1973a, b). In India, the tribals of Sonaghati of Sonbhadra district, Uttar Pradesh, used the plant to treat tumour and swelling and as an antidote to snakebite and stings (Singh et al. 2002). In Nepal, leaf sap is applied on fresh cuts (Shrestha and Joshi 1993); leaves are applied to cuts and wounds for antihaemorrhagic and antiseptic properties (Bhattarai 1991); leaves and aerial parts for cuts, wounds and to treat stomach upset (Joshi and Joshi 2000).

Other Uses

In Hawaii and Polynesia, the fragrant flowers are used for leis, scent and medicine.

The plant has potential to be used as a biocontrol agent to control weeds, agricultural and veterinary insect pests and plant diseases as it has been reported to contain phytochemicals and allelochemicals that are toxic to plant weeds, insect pests and plant pathogens.

A crude lipid extract from the *Ageratum conyzoides* exerted ovicidal action and induced sterility after topical treatment of both young last instar larvae (L_6) and females of *Dysdercus flavidus* Sign, at emergence by inhibiting ovarian development (Fagoonee and Umrit 1981). The action of the two chromenes precocenes I and II in the crude extract was synergistic. Precocene I and II from *A. conyzoides* exhibited antijuvenile hormone activity against *Sitophilus oryzae*, *Thlaspidia japonica* and *Leptocorisa chinensis* (Lu 1982). Highly toxic properties were exhibited by fractions F and G of the chloroform leaf extract of *A. conyzoides* against *Drosophila melanogaster* and fractions C, D, E, F and G against *Dysdercus cingulatus* (Alcantara 1985). These results were comparable with that obtained for the standard insecticide malathion and relatively high as compared with the natural insecticide rotenone. Purification of fraction D and E afforded 2H-1-benzopyran-2-one (coumarin) and a dimer of ageratochromene. Compound 1 was

found to be highly toxic to *Drosophila melanogaster* and *Dysdercus cingulatus*. Compound 2 was found to be generally nontoxic to the test insects.

A. conyzoides methanol extract from fresh leaves (250 and 500 ppm) adversely producing a deficiency of juvenile hormone affecting the development of the fourth instar of *Chilo partellus* (Lepidoptera, Pyralidae), a sorghum pest, as evidenced by the presence of a dark stain in the insects' cuticle and immature pupae formation (Raja et al. 1987). Studies found that the leaf extract from *A. conyzoides* at 25 % concentration killed 36.7 % of the population of *Dasynus piperis*, a major pest of black pepper berries (Mustikawati and Nazar 1996). The extract of *Lantana camara* flowers at 10 % concentration killed 30 %, while the extract of *Ageratum conyzoides* flowers at 25 % concentration killed 50 % and aquadest killed 3.3 %. The topical application of the essential oil of *Ageratum conyzoides* to the nymphs of the desert locust *Schistocerca gregaria* showed high nymphal mortality (91 %) (Pari et al. 1998). Essential oil of the plant was toxic to the adults of the cowpea weevil (*Callosobruchus maculatus*) (Gbolade et al. 1999).

An unsaturated branched chain fatty acid (Z)-6-methyl-12-heptadecenoic acid from *A. conyzoides* essential oil demonstrated insecticidal and growth regulatory activity against *Schistocerca gregaria* (Pari et al. 2000). Besides mortality, the compound also caused disturbances at the nymphal-adult moult resulting in deformity. In-vitro studies showed that the essential oil of *Ageratum conyzoides* leaves was the most effective insecticide against the maize grain weevil, *Sitophilus zeamais* ($LD_{50}=0.09$ % in 24 hours), followed by that of *Lantana camara* ($LD_{50}=0.16$ %) and *Chromolaena odorata* ($LD_{50}=6.78$ %) (Bouda et al. 2001). The mortality of *S. zeamais* increased with the concentration of the essential oils of the three plants and the duration of exposure of the weevils on the treated maize grains. The hexane and alcohol extracts of *A. conyzoides* showed insecticidal activity against the larvae of the lepidopteran pest *Diaphania hyalinata* (Moreira et al. 2004). Fractionation of the hexane

extract afforded the following active compounds 5,6,7,8,3',4',5'-heptamethoxyflavone; 5,6,7,8,3'-pentamethoxy-4',5'-methylenedioxyflavone and coumarin. The increasing order of susceptibility to coumarin was *Diaphania hyalinata* < *Dione juno juno* < *Tuta absoluta*. The increasing order of toxicity to *D. juno juno* was 5,6,7,8,3'-pentamethoxy-4',5'-methylenedioxyflavone < coumarin < 5,6,7,8,3',4',5'-heptamethoxyflavone. The hexane extract of *A. conyzoides* showed insecticidal activity (Moreira et al. 2007). Three compounds were identified: 5,6,7,8,3',4',5'-heptamethoxyflavone, 5,6,7,8,3'-pentamethoxy-4',5'-methylenedioxyflavone and coumarin. The *A. conyzoides* extract showed good repellence index (66 %) of *Amblyomma cajennense* nymphs (Cayenne tick) when applied in high concentrations (Soares et al. 2010). Lima et al. (2010) demonstrated that ingestion of maize leaf sections treated with *A. conyzoides* essential oil (0.5 % concentration) by the fall armyworm *Spodoptera frugiperda* caused >70 % mortality. The major component of the essential oil from *A. conyzoides* was found to be precocene (87.0 %).

Aqueous extract of *A. conyzoides* plant was found to reduce larvae emergence of the root-knot nematode, *Meloidogyne incognita* (Shabana et al. 1991). The ethanol extract of *A. conyzoides* leaves was more potent against embryonation (39.6 %) of the parasitic nematode *Heligmosomoides bakeri* than the aqueous extract (53.3 %) at the highest concentration (3.75 mg/ml) (Wabo Poné et al. 2011). Both types of extracts also killed larvae with higher larvicidal activity shown by the ethanol extract.

All the employed concentrations of (2, 4 and 6 % w/v) of aqueous, methanol, and *n*-hexane extracts of *A. conyzoides* inflorescence, leaf, stem and root significantly suppressed the growth of the plant pathogen, *Fusarium solani* (Javed and Bashir 2012). The *n*-hexane extracts of leaf and inflorescence caused highly significant reduction of 84 % in growth of *F. solani* followed by stem and root extracts which caused 80 and 72 % reduction in growth, respectively. The same pattern in growth reduction was observed in methanol and aqueous extracts. Among the four parts

of the tested weed, different concentrations of the methanol extract of leaf were found to be highly effective in controlling target fungal species, resulting in up to 78 % reduction in fungal biomass over control followed by inflorescence (74 % reduction), stem (63 % reduction) and root (59 % reduction) at highest used concentration. In case of aqueous extracts, the maximum reduction was observed in leaf extract (72 %) followed by inflorescence, stem and root, respectively.

Volatile oil from *Ageratum conyzoides* was found to have allelopathic activity (Kong et al. 1999). Precocene I, precocene II, β -caryophyllene and 3,3-dimethyl-5-*tert*-butylindone isolated from *A. conyzoides* leaf oil inhibited seedling growth of acceptor plants. Inhibitory activity of the volatile oil was more intense than that of the pure components. Fenchyl acetate and γ -bisabolene had no inhibitory activity, but when mixed with precocene II, they increased the inhibitory activity to growth of acceptor seedling plants. The inhibitory allelopathic effects of *A. conyzoides* volatiles on peanut (*Arachis hypogaea*), redroot amaranth (*Amaranthus retroflexus*), cucumber (*Cucumis sativus*) and ryegrass (*Lolium multiflorum*) increased when plants were grown under nutrient-deficient conditions or in competition with *Bidens pilosa* (Kong et al. 2002). Volatiles from *A. conyzoides* plants infected with *Erysiphe cichoracearum* (powdery mildew fungus) or exposed to *Aphis gossypii* feeding inhibited or killed fungi and insects. Precocenes and their derivatives, monoterpenes and sesquiterpenes, were found to be the major volatile components of *A. conyzoides*.

The residue obtained from an aqueous acetone extract of *Ageratum conyzoides* shoots inhibited the germination and the growth of roots and shoots of *Amaranthus caudatus*, *Digitaria sanguinalis* and *Lactuca sativa* (Kato-Noguchi 2011). The concentration-dependent responses of the test plants suggested that the residue of *Ageratum conyzoides* might contain allelochemical(s). *Ageratum conyzoides* showed potential to be used as a natural herbicide for weed control in paddy fields to reduce the dependence on synthetic herbicides (Xuan et al. 2004).

A. conyzoides exhibited strong inhibition on *Raphanus sativus* (radish) germination and growth in a bioassay with the leaves eliciting a greater suppression than the stem and root. The leaves of *A. conyzoides* applied at 2 t/ha reduced about 70 % of the growth of *Echinochloa crus-galli* var. *formosensis* and completely inhibited emergence of *Monochoria vaginalis* var. *plantaginea* and *Aeschynomene indica* in calcareous soil condition. Application of *A. conyzoides* leaves at 2 t/ha in a paddy field 2 days after transplanting caused about 75 % paddy weed reduction and increased yield by 14 % compared with a herbicide treatment. Three phenolic compounds were identified in the leaves, stem and root including gallic acid, coumalic acid and protocatechuic acid, and catechin was found only in the stem. *p*-Hydroxybenzoic acid was detected in both *A. conyzoides* leaves and stem. Three additional putative allelochemicals were found in the leaves consisting of *p*-coumaric acid, sinapic acid and benzoic acid. The greater number of growth inhibitors found in the leaves might result in the stronger inhibitory activity than the stem and root.

Intercropping *Ageratum conyzoides* in citrus orchards may effectively suppress weeds and control other insect pests and diseases (Kong et al. 2002; Hu et al. 2002; Hu and Kong 2002; Kong et al. 2004, 2005). Investigations showed that the inhibition of major weeds and soil pathogenic fungi in citrus orchards was significantly correlated with the allelochemicals released into the soil by intercropped *A. conyzoides*. Three flavones, 5,6,7,8,3',4'5'-heptamethoxyflavone, 5,6,7,3',4',5'-hexamethoxyflavone, 5,6,8,3',4',5'-hexamethoxyflavone, and ageratochromene and its two dimers were isolated and identified from the *A. conyzoides* intercropped citrus orchard soil. Three flavones and ageratochromene could significantly inhibit the growth of weeds *Bidens pilosa*, *Digitaria sanguinalis* and *Cyperus difformis* and spores germination of soil pathogenic fungi *Phytophthora citrophthora*, *Pythium aphanidermatum* and *Fusarium solani*. However, two dimers of ageratochromene had no inhibitory actions on them (Kong et al. 2004). Earlier their studies showed flavones produced by and

released from *A. conyzoides* could inhibit the major fungal pathogens, such as *Elsinoe fawcettii*, *Colletotrichum gloeosporioides*, *Oidium tingtonum* and *Capnodium citri* in citrus orchard (Hu et al. 2002). Ten flavones, including one glycoside, from *A. conyzoides* plant were isolated and identified. The inhibitory effect of three flavones 5,6,7,8,3',4'5'-heptamethoxyflavone, 5,6,7,3',4',5'-hexamethoxyflavone, and 5,6,8,3',4',5'-hexamethoxyflavone was stronger, not only than those of other allelochemicals produced by and released from *A. conyzoides*, but also than that of Carbenzin, a commercial fungicide. The presence of these allelochemicals in soils suggests that they may be able to make a major contribution to control some weeds and diseases in citrus orchards. Hu and Kong (2002) found that the allelopathic potential of *A. conyzoides* decreased because of favourable growing seasons in spring and summer. On the contrary, autumn and winter were unfavourable growing seasons, and the allelopathic potential of *A. conyzoides* increased. In the laboratory, under high or low temperatures and shading conditions, inhibitory effects of allelochemicals of *A. conyzoides* on tested plants intensified significantly at low concentration. It revealed that under unfavourable growing conditions, tested plants resistance to the allelochemicals of *A. conyzoides* decreased. When *A. conyzoides* and tested plants both grew under unfavourable meteorological conditions, allelopathic potential of *A. conyzoides* increased and the tested plants resistant ability to allelochemical decreased. Kong et al. (2005) demonstrated that *A. conyzoides* produced and released volatile allelochemicals into the air in the intercropped citrus orchard, and these volatiles influenced the olfactory responses of predatory mite *Amblyseius newsami*, an effective natural enemy of citrus red mite and citrus red mite *Panonychus citri*. At test temperature (25 °C), *A. conyzoides* fresh leaves, its essential oil, and major constituents, demethoxy-ageratochromene, β -caryophyllene, α -bisabolene, and *E*- β -farnesene, attracted *A. newsami* and slightly repelled *P. citri*. Field experiments demonstrated that spraying *A. conyzoides* essential oil emulsion in an *A. conyzoides* nonintercropped citrus orchard

increased the population density of *A. newsami* from below 0.1 to over 0.3 individuals per leaf, reaching the same level as in an *A. conyzoides* intercropped citrus orchard. However, this effect could not be maintained beyond 48 hours because of the volatility of the essential oil. In contrast, in the *A. conyzoides* intercropped citrus orchard, *A. conyzoides* plants continuously produced and released volatile allelochemicals and maintained the *A. newsami* population for a long time. The results suggested that intercropping of *A. conyzoides* not only made the citrus orchard ecosystem more favourable for the predatory mite *A. newsami*, but also that the volatile allelochemicals released from *A. conyzoides* regulated the population of *A. newsami* and *P. citri*. Gravena et al. (1993) observed lower incidences of mites *Phyllocoptura oleivora* and *Brevipalpus phoenicis* and higher population densities of predatory phytoseiids in citrus trees with green ground cover of *Ageratum conyzoides* and *Eupatorium pauciflorum* than in trees without weeds.

Comments

Ageratum conyzoides is considered an invasive, noxious environmental weed in Asia, Africa, America, and the Pacific Islands.

Argyranthemum frutescens

Scientific Name

Argyranthemum frutescens (L.) Sch. Bip.

Synonyms

Anthemis frutescens Voss, *Chrysanthemum floridum* Salisb., *Chrysanthemum foliosum* Brouss. ex DC., *Chrysanthemum frutescens* L., *Chrysanthemum fruticosum* Buch, *Matricaria frutescens* (L.), *Pyrethrum frutescens* (L.) Gaertn., *Pyrethrum frutescens* (L.) Willd.

Family

Asteraceae

Common/English Names

Boston Daisy, Cobbity Daisy, Dill Daisy, Federation Daisy, Marguerite, Marguerite Daisy, Paris Daisy, Paris Marguerite, Summer Daisy, Teneriffe Daisy, White Marguerite

Vernacular Names

Catalan: Margaridera

Czech: Kopretinovec Dřevnatý

Danish: Almindelig Buskmargerit

Dutch: Struikmargriet

Finnish: Marketta (Kasvi)

French: Anthémis, Marguerite

German: Strauchmargerite

Italian: Margherita Delle Canarie

Marjocan: Margalidera Gran, Margalides, Margaridera

Spanish: Margarita

Swedish: Buskmargerit

Origin/Distribution

The species is native to Canary Islands in Macaronesia. It has naturalized in Australia, New Zealand, East Europe, Ukraine and is adventive in Norway, Germany, and Italy.

Agroecology

Marguerite Daisy thrives in areas with a Mediterranean to subtemperate climate. It grows easily in moderately fertile, medium-textured and well-drained soils. It is wind and salt tolerant.

Edible Plant Parts and Uses

The flowers are edible (Rop et al. [2012](#)).

Botany

A short-lived, perennial herb or subshrub 10–80 (–150 cm) high with a prostrate to erect, branched, glabrous stem. Leaves are alternate, 2–3 pinnately divided, lobes wedge-shaped to linear, ultimate margins serrated rarely entire (Plate 1). Inflorescence a lax irregular cyme often reduced to a solitary capitulum. Involucre hemispherical cup-shaped, phyllaries in 3–4 series, free, persistent in fruit, oblanceolate or ovate to lanceolate-deltate or lanceolate, margins and tips yellow to brown, scarious, tips of inner often expanded; receptacle convex to conic. Ray flowers 12 to >25, ray ovate to linear, female, white, sometimes pink or yellow. Disk flowers 50–80 to >150, bisexual, fertile, corolla white, yellow (pink, red or purple), tubular, 5-deltoid lobed, anther with ovate tips, styler tip truncate, papillate (Plates 1, 2 and 3). Fruit subterete or obovoid achene, faintly 5–8 ribbed without pappus.

Nutritive/Medicinal Properties

Rop et al. (2012) reported that edible flowers of *Argyranthemum frutescens* had a dry matter content (%w/w) of 9.57 %, crude protein of 6.85 g/kg, and the following elements (mg/kg) fresh mass (FM): P 428.36 mg, K 2617.24 mg, Ca 258.55 mg, Mg 105.26 mg, Na 89.10 mg, Fe 5.15 mg, Mn 7.86 mg, Cu 2.20 mg, Zn 5.49 mg, and Mo 0.30 mg.

Argyranthemum frutescens flowers were found to emit the benzenoid volatile, phenylacetaldehyde, to attract foraging insects like moths (Cunningham et al. 2006).

Leaf extract of *A. frutescens* containing biologically active components such as tetradecanoic acid, pentadecanoic acid, hexadecanoic acid, phytol, linalool, 1,8-cineole, and 9, 12, 15-octadecanoic acid was found to be effective against the damping-off pathogen of sugar beet, *Sclerotium rolfsii* (Derbalah et al. 2012a).

Plate 1 Leaves and white-yellow flowers of Marguerite Daisy

Plate 2 Pale purple Marguerite Daisy flowers

Plate 3 Bright pink Marguerite Daisy flower

Antioxidant Activity

Marguerite Daisy was found to have a total antioxidant capacity of 4.24 g ascorbic acid equivalent/kg fresh mass (FM), a total phenolic content

of 2.53 g gallic acid/kg/FM, and total flavonoid content of 1.23 g rutin/kg FM (Rop et al. 2012).

Traditional Medicinal Uses

Marguerite Daisy has been used in the treatment of whooping cough, asthma and nervous excitability. The sticky leaves have been used in wound dressing. An eye lotion for conjunctivitis can be made from the flowers.

Other Uses

The species, cultivars and hybrids are planted as ornamental plants in gardens and parks. The flowers are also used for cut flower arrangements.

The leaves have insecticidal properties. Derbalah et al. (2012b) found that increasing the concentration level of all tested treatments (from 100 to 300 ppm) reduced the emergence of the rice weevil, *Sitophilus oryzae*, even more (concentration dependent) malathion (86 %) followed by *Caesalpinia gilliesii* (79 %) extract and *Chrysanthemum frutescens* leaf extract (73 %), while *Cassia senna* extract was the least effective. The results showed that *C. gilliesii* (100 %) was the most effective treatment against *S. oryzae* adults followed by *C. frutescens* (95.6 %), *Thespesia populnea* var. *acutiloba* (88 %), *Euonymus japonicus* (85 %), *Bauhinia purpurea* (75 %), *C. senna* (80 %), and *Cassia fistula* (70 %),

respectively. Malathion (100 %) and *C. gilliesii* (100 %) extract were the most effective treatments on adult's mortality of *S. oryzae* after 2 weeks, while *C. fistula* extract (70 %) was the least effective.

Comments

The species is regarded as environmental weed in South Australia and Western Australia.

Origin/Distribution

The species is native to western, central and northern Europe and middle Asia. It has been introduced to North America and New Zealand. The species is widely naturalized in North America.

Agroecology

B. perennis is a cool climate perennial herbaceous plant grown as a biennial or annual. The plant is found wild in meadows and uncultivated pastures in its native range. It prefers full sun to light shade and organically rich, fertile, consistently moist and well-drained soils. It flowers in spring and declines with summer heat where it is often removed. The plant is intolerant of drought.

Edible Plant Parts and Uses

The leaves and flowers are used as vegetables (Yoshikawa et al. 2008). Flower buds and petals have a mildly bitter taste and can be eaten raw, in

salads, sandwiches, soups or as garnish or in tea (Cribb and Cribb 1982; Facciola 1990). Young leaves can be eaten raw in salads or cooked as potherbs (Hedrick 1972; Larkcom 1980; Chiej 1984; Facciola 1990; Bown 1995).

Botany

An herbaceous perennial or annual plant, 10–25 cm high with creeping rhizomes and sparsely strigose scape. Leaves basal and rosulate with long winged petioles; lamina spatulate, 2–6 cm by 1–2.8 cm, with serrated to crenate margins, attenuated base and apex obtuse, sometimes retuse, mucronulate (Plate 1). Capitula terminal, solitary, 2–3 cm across (Plates 1, 2, 3 and 4). Involucre hemispheric or broadly campanulate, 5–6 mm; phyllaries 2-seriate, subequal, oblanceolate, leaflike, surfaces pubescent, margin sparsely ciliate, midvein thin, translucent, apex obtuse, scarious, ciliate. Ray florets white or pinkish or in various shades of red, purple, pink (Plates 1, 2, 3 and 4), lamina about 10×1 mm; disk florets yellow, 2 mm, limb campanulate, about 1.5 mm, sparsely pubescent proximally, lobes erect, triangular, eglandular. Cypselae strigillose 1–2 mm. Pappus absent.

Nutritive Value and Medicinal Properties

The major anthocyanin of red flowers of *Bellis perennis* was identified as cyanidin 3-*O*-(6-*O*-matonyl-4-*O*-(β-D-glucuronyl)-β-D-glucopyranoside) (Saito et al. 1988). The malonylanthocyanin was more stable in neutral solution than cyanidin 3-glucoside but less stable than cyanidin 3-glucuronylglucoside. The anthocyanins, cyanidin 3-*O*-(4''-*O*-(malonyl)-2''-*O*-(β-D-glucuronyl)-β-D-glucopyranoside) and cyanidin 3-*O*-(2''-*O*-(β-D-glucuronyl)-β-D-glucopyranoside) were isolated from the red flowers of *Bellis perennis* cv. 'Super Siberius Crimson' (Toki et al. 1991). A known malonylated cyanidin 3-glucuronylglucoside was also obtained as a major pigment, and its structure was revised to the cyanidin

Plate 1 Leaves and terminal white flower head

Plate 2 Dark red flower heads

Plate 3 Close view of pink flower heads

Plate 4 Close view of red flower heads

3-*O*-(6''-*O*-(malonyl)-2''-*O*-(β-D-glucuronyl)-β-D-glucopyranoside). Seven acylated triterpene saponins, perennisosides I–VII, were isolated together with four known saponins, bellidioside A, asterbatanoside D, bernardioside B 2 and bellissaponin BS6 and were isolated from *B. perennis* flowers (Morikawa et al. 2008). The structure of perennisoside I was determined as 23-*O*-acetyl bayogenin 28-*O*-α-L-rhamnopyranosyl(1 → 2)[β-D-glucopyranosyl(1 → 3)]-6-*O*-acetyl-β-D-glucopyranoside; the structure of perennisoside II was elucidated as 23-*O*-acetyl bayogenin 28-*O*-R-L-rhamnopyranosyl(1 → 2)[β-D-galactopyranosyl(1 → 3)]-6-*O*-acetyl-β-D-glucopyranoside; the structure of perennisoside III was established as 3-*O*-β-D-glucopyranoside of bayogenin 28-*O*-α-L-rhamnopyranosyl(1 → 2)[β-D-glucopyranosyl(1-3)]-6-*O*-acetyl-β-D-glucopyranoside; perennisoside IV was elucidated as 3-*O*-β-D-glucopyranoside of bayogenin 28-*O*-α-L-rhamnopyranosyl(1 → 2)[β-D-galactopyranosyl(1 → 3)]-6-*O*-acetyl-β-D-glucopyranoside; perennisoside V was assigned as 3-*O*-β-D-glucopyranoside of 23-*O*-acetyl bayogenin 28-*O*-α-L-rhamnopyranosyl(1-2)[β-D-glucopyranosyl(1-3)]-β-D-glucopyranoside; the structure of perennisoside VI was determined as 3-*O*-β-D-glucopyranoside of 23-*O*-acetyl bayogenin 28-*O*-R-L-rhamnopyranosyl(1 → 2)[β-D-galactopyranosyl(1 → 3)]-β-D-glucopyranoside and the structure of perennisoside VII was elucidated as 3-*O*-β-D-glucopyranoside of 23-*O*-acetyl bayogenin 28-*O*-R-L-rhamnopyranosyl(1 → 2)[β-D-galactopyranosyl(1 → 3)]-6-*O*-acetyl-β-D-

glucopyranoside. Five new oleanane-type triterpene saponins named perennisosides VIII–XII were isolated from the flowers (Morikawa et al. 2011). Perennisoside VIII was determined to be 3-*O*- β -D-fucopyranosyl-23-*O*-acetylbaoyogenin {28-*O*- α -L-rhamnopyranosyl-(1 \rightarrow 2)-[β -D-glucopyranosyl(1 \rightarrow 3)]-6-*O*-acetyl- β -D-glucopyranosyl} ester; perennisoside IX was determined to be 3-*O*- β -D-fucopyranosyl-23-*O*-acetylbaoyogenin {28-*O*- α -L-rhamnopyranosyl(1 \rightarrow 2)-[β -D-galactopyranosyl(1 \rightarrow 3)]-6-*O*-acetyl- β -D-glucopyranosyl} ester; perennisoside X was determined to be 3-*O*- β -D-glucopyranosyl-(1 \rightarrow 3)- β -D-glucopyranosyl-23-*O*-acetylbaoyogenin {28-*O*- α -L-rhamnopyranosyl(1 \rightarrow 2)-[β -D-glucopyranosyl(1 \rightarrow 3)]-6-*O*-acetyl- β -D-glucopyranosyl} ester; perennisoside XI was 3-*O*- β -D-glucopyranosyl-(1 \rightarrow 3)- β -D-glucopyranosyl-23-*O*-acetylbaoyogenin {28-*O*- α -L-rhamnopyranosyl(1 \rightarrow 2)-[β -D-galactopyranosyl(1 \rightarrow 3)]-6-*O*-acetyl- β -D-glucopyranosyl} ester and perennisoside XII was elucidated as baoyogenin {28-*O*- α -L-rhamnopyranosyl-(1 \rightarrow 2)-[β -D-galactopyranosyl(1 \rightarrow 3)]-[β -D-glucopyranosyl-(1 \rightarrow 6)]- β -D-glucopyranosyl} ester. Deacylation of perennisosides VIII, IX, X and XI afforded desacyl-perennisoside VIII, desacyl-perennisoside IX, desacyl-perennisoside X and desacyl-perennisoside XI.

Six acylated oleanane-type triterpene oligoglycosides, perennisaponins A, B, C, D, E and F, were isolated from the flowers together with 14 saponins, nine flavonoids and two glycosides (Yoshikawa et al. 2008). Seven new acylated oleanane-type triterpene bisdesmosides designated perennisaponins G, H, I, J, K, L and M and were isolated from the flowers (Morikawa et al. 2010). Several triterpene saponins (Glensk et al. 2001) and five new triterpene saponins perennisosides VIII, IX, X, XI and XII were isolated from *Bellis perennis* flowers (Morikawa et al. 2011).

Bellis perennis flowers were found to contain the following flavonoid compounds: quercetin, apigenin, apigenin 7-*O*- β -D-glucuronide, apigenin 7-*O*- β -D-glucoside, apigenin 7-*O*- β -D-methylglucuronide, apigenin 7-*O*- β -D-(6''-*E*-caffeoyl)-glucoside, isorhamnetin, isorhamnetin 3-*O*- β -D-galactoside, isorhamnetin 3-*O*- β -D-(6''-

acetyl)-galactopyranoside, kaempferol, kaempferol 3-*O*- β -D-glucoside and kaempferol 3-*O*- β -D-glucopyranoside (Gudej and Nazaruk 1997; Nazaruk and Gudej 2000; Gudej and Nazaruk 2001; Nazaruk and Gudej 2001). Similar flavonoids were found in cultivated and wild daisy flowers, while differences were noted in the flavonoid composition of the leaves (Nazaruk and Gudej 2001). The flavonoid contents were higher in the flowers than in the leaves. In cultivated and wild daisy flowers, apigenin, apigenin 7-*O*- β -D-glucoside, apigenin 7-*O*- β -D-glucuronide, apigenin 7-*O*- β -D-methylglucuronide, kaempferol, kaempferol 3-*O*- β -D-glucoside, isorhamnetin 3-*O*- β -D-galactoside, isorhamnetin 3-*O*- β -D-(6''-acetyl)-galactoside and quercetin were detected. In the flowers of wild growing daisy, apigenin 7-*O*- β -D-(6''-*E*-caffeoyl)-glucoside was detected. In the leaves apigenin, apigenin 7-*O*- β -D-glucoside, apigenin 7-*O*- β -D-glucuronide, kaempferol, kaempferol 3-*O*- β -D-glucoside, isorhamnetin 3-*O*- β -D-galactoside and quercetin were found. Caffeic acid and seven of its derivatives were isolated from leaves of *Bellis perennis* (Scognamiglio et al. 2012). A novel glucuronosyltransferase, BpUGAT, involved in the biosynthesis of flower pigments in the red daisy (*Bellis perennis*) was purified (Sawada et al. 2005). BpUGAT was a soluble monomeric enzyme with a molecular mass of 54 kDa and catalyzed the regiospecific transfer of a glucuronosyl unit from UDP-glucuronate to the 2''-hydroxyl group of the 3-glucosyl moiety of cyanidin 3-*O*-6''-*O*-malonylglucoside. It was highly specific for cyanidin 3-*O*-glucosides cyanidin 3-*O*-6''-*O*-malonylglucoside and UDP-glucuronate.

The essential oil of *B. perennis* leaves and flowers were found to contain polyacetylenes (18–21 %) and terpenoids (Avato and Tava 1995). The major polyacetylenes identified were methyl deca-4,6-diynoate (2,8-tetrahydromatricaria ester) and deca-4,6-diynoic acid. The major polyacetylenes identified from the aerial organs of *Bellis perennis* were methyl deca-4,6-diynoate and deca-4,6-diynoic acid and their structural analogues, deca-4,6-diyne, dimethyl octa-3,5-diyne-1,8-dioate and deca-4,6-diyne-1,10-dioic acid (Avato et al. 1997).

A triterpenoid saponin isolated from *B. perennis* named bellissaponin BS3 was shown to be identical to virgaureasaponin 2 previously isolated from *Solidago virgaurea* (Schopke et al. 1990). Two acylated triterpenoid saponins, bellissaponins BA1 and BA2, isolated from *Bellis perennis* were elucidated as 3-*O*- α -L-rhamnopyranosyl and 3-*O*- β -D-glucopyranosyl-2 β ,3 β ,16 α ,23-tetrahydroxyolean-12-ene-28-oic acid-28-*O*- α -L-rhamnopyranosyl (1 \rightarrow 3)- β -D-xylopyranosyl(1 \rightarrow 4)- α -L-rhamnopyranosyl(1 \rightarrow 2)-[*E*-buta-2-enoic acid(1 \rightarrow 4)]- β -D-fucopyranoside (Schöpke et al. 1991). Four triterpenoid saponins were isolated from the underground parts of *Bellis perennis*. Their structures were elucidated as 3-*O*- β -D-glucopyranosides of 2 β ,3 β ,16 α -trihydroxyolean-12-ene-28-oic acid-28- α -L-rhamnopyranosyl(1 \rightarrow 2)-[β -D-glucopyranosyl(1 \rightarrow 6)]- β -D-glucopyranoside, 2 β ,3 β ,23-trihydroxyolean-12-ene-28-oic acid-28-*O*- β -D-xylopyranosyl (1 \rightarrow 2)-[β -D-glucopyranosyl(1 \rightarrow 6)]- β -D-glucopyranoside and 2 β ,3 β ,23-trihydroxyolean-12-ene-28-oic acid-28-*O*- α -L-rhamnopyranosyl(1 \rightarrow 2)-[β -D-glucopyranosyl(1 \rightarrow 6)]- β -D-glucopyranoside and as 3-*O*- α -L-rhamnopyranosyl-2 β ,3 β ,23-trihydroxyolean-12-ene-28-oic acid-28-*O*- β -D-glucopyranosyl(1 \rightarrow 2)-[β -D-glucopyranosyl(1 \rightarrow 6)]- β -D-glucopyranoside (Schöpke et al. 1992). Four triterpenoid saponins were isolated from the underground parts of *Bellis perennis* and their structures were elucidated as 3-*O*- β -D-glycopyranosides of 2 β ,3 β ,16 α -trihydroxyolean-12-ene-28-oic acid-28- α -L-rhamnopyranosyl(1 \rightarrow 2)-[β -D-glucopyranosyl(1 \rightarrow 6)]- β -D-glucopyranoside, 2 β ,3 β ,23-trihydroxyolean-12-ene-28-oic acid-28-*O*- β -D-xylopyranosyl (1 \rightarrow 2)-[β -D-glucopyranosyl(1 \rightarrow 6)]- β -D-glucopyranoside and 2 β ,3 β ,23-trihydroxyolean-12-ene-28-oic acid-28-*O*- α -L-rhamnopyranosyl (1 \rightarrow 2)-[β -D-glucopyranosyl(1 \rightarrow 6)]- β -D-glucopyranoside and as 3-*O*- α -L-rhamnopyranosyl-2 β ,3 β ,23-trihydroxyolean-12-ene-28-oic acid-28-*O*- β -D-glucopyranosyl(1 \rightarrow 2)-[β -D-glucopyranosyl(1 \rightarrow 6)]- β -D-glucopyranoside (Wray et al. 1992). Six acylated triterpenoid saponins, bellisoides A–F, together with a known saponin, bellissaponin BS2 were isolated from the roots of *Bellis perennis* (Li et al. 2005).

Antioxidant Activity

The antioxidant activity of the flowers using a 1,1-diphenyl-2-picrylhydrazyl (DPPH) radical scavenging assay expressed as IC₅₀ values varied from 66.03 to 89.27 μ g/ml; it is about 50, 30, 20 and 10 times lower as compared with quercetin, ascorbic acid, Trolox and butylhydroxytoluene, respectively, and about 5 times higher in comparison with apigenin-7-glucoside. The contents of flavonoids in the flowers varied from 0.31 to 0.44 mg quercetin equivalent/100 mg dry weight and from 1.37 to 2.20 mg apigenin-7-glucoside equivalent/100 mg dry weight (Siatka and Kašparová 2010). Total phenolics ranged from 2.81 to 3.57 mg gallic acid equivalent/100 mg dry weight. There is a significant correlation between antioxidant activity and total phenolics. No correlation between total flavonoid contents and antioxidant activity was observed. The aqueous extracts of aerial plant parts showed higher DPPH scavenging activity (85.8 % at 102.5 μ g/ml) than the methanol extract (Kavalcioğlu et al. 2010). Reducing power was also observed for both tested extracts, where the formation of linoleic acid peroxides was more for the aqueous extract than the methanol extract.

Anxiolytic and Antidepressant Activities

B. perennis aqueous flower extract was found to elicit biphasic effects on both anxiety-like behavior and learning performance of the rats (Karakaş et al. 2011). In the open field, rats administered the high dose of *B. perennis* aqueous flower extract spent more time at the centre, showed less mobility and velocity. In the elevated plus maze, rats administered the high dose of *B. perennis* caused to spend more time in the open arms, spent less time in the closed arms, were less mobile, were slower and rotated less frequently. In the Morris water maze, rats administered the high dose of *B. perennis* spent more of the time to find the platform.

Oral administration of the crude ethanol flower extract of *B. perennis* elicited anxiolytic and antidepressant-like effects in mice (Marques et al. 2012). In the open field test, there was a significant decrease in the number of crossings at dosages of 50, 100 and 150 mg/kg but no sedative effects at any dosages when compared to controls. In the forced swimming test (FST), the extract dosage of 150 mg/kg was effective in reducing immobility, along with a significant increase in swimming time. The ethanol extract showed strong antioxidant potential in vitro, through the removal capacity against hydroxyl radicals and nitric oxide as well as prevented the formation of reactive substances to thiobarbituric acid (TBARS).

Neuroprotective Activity

Results of animal studies suggested that the ethanol flower extract of *B. perennis* may modulate epileptogenesis and promote anticonvulsant and neuroprotective mechanisms in model of seizures induced by pilocarpine (Marques et al. 2011). Adult Swiss mice treated with pilocarpine exhibited seizures that progressed to status epilepticus; 87.5 % of animals had brain damage in the hippocampus and the damage rate in striatum was 75 %. Pretreatment with the ethanol flower extract produced a significant reduction in these indices.

Antihyperlipidemic Activity

Among seven acylated triterpene saponins isolated from *B. perennis*, perennisosides I and II showed inhibitory effects on serum triglyceride elevation at doses of 25–50 mg/kg, p.o. in olive-treated mice (Morikawa et al. 2008). The methanol extract from *B. perennis* flowers was found to show pancreatic lipase inhibitory activity (IC₅₀ 455 µg/ml). From the extract, seven new triterpene saponins named perennisosaponins G (IC₅₀ 163 µM), H (137 µM), I (147 µM), J (148 µM), K (223 µM), L (81.4 µM) and M (195 µM) were isolated as pancreatic lipase inhibitors (Morikawa et al. 2010).

Anticancer Activity

Six acylated triterpenoid saponins, bellisosides A–F, together with a known saponin, bellissaponin BS2 isolated from *Bellis perennis* roots exhibited cytotoxic activities against HL-60 human promyelocytic leukaemia cells (Li et al. 2005).

Antimicrobial Activity

Triterpenoid glycosides obtained *Bellis perennis* inhibit the growth of human-pathogenic yeasts (*Candida* and *Cryptococcus* species) (Bader et al. 1990). Ester saponin, bellissaponin from *B. perennis*, exerted antifungal effect against *Candida albicans*, *Trichophyton rubrum*, *Trichophyton mentagrophytes* and *Aspergillus niger* (Willigmann et al. 1992). The intensity of growth inhibition was influenced particularly by the carbohydrate chains of the glycosides. Monodesmosidic as well as bis-desmosidic glycosides of polygalacic acid exerted fungicidal effects. Of the major polyacetylenes identified from the aerial organs of *Bellis perennis* methyl deca-4,6-diyne and deca-4,6-diyneic acid and their structural analogues, deca-4,6-diyne, dimethyl octa-3,5-diyne-1,8-dioate and deca-4,6-diyne-1,10-dioic acid, only deca-4,6-diyneic acid and deca-4,6-diyne-1,10-dioic acid showed antimicrobial activity, being mainly effective against Gram-positive and Gram-negative bacteria (Avato et al. 1997).

Wound Healing Activity

Topically administered ointment prepared from the *n*-butanol fraction of *B. perennis* flowers was found to have a wound healing potential without scar formation in circular excision wound model in rats, verifying the traditional usage of *B. perennis* for wound healing (Karakaş et al. 2012).

Gastric Emptying Inhibition Activity

The methanol-eluted fraction of the methanol extract from *B. perennis* flowers was found to

inhibit gastric emptying in olive oil-loaded mice at a dose of 200 mg/kg, per os (p.o.) (Morikawa et al. 2011).

Antihæmorrhagic Activity

In a double-blind, placebo-controlled, randomized, clinical trial of 40 parturients, treatments with homeopathic *Arnica montana* and *Bellis perennis* were found to reduce postpartum blood loss, as compared with placebo (Oberbaum et al. 2005).

Haemolytic activity

The haemolytic activity of *B. perennis* flower head varied with seasonal changes, being lowest in March, increasing to a maximum in summer months (June, July, August), and then decreasing again (Siatka and Kasparová 2003).

Antiulcerogenic Activity

Oral administration of the aqueous and methanol extracts of *B. perennis* aerial parts (1,100 and 600 mg/kg) reduced gastric ulcers in rats with ethanol-induced gastric ulcers. Both extracts exhibited significant antiulcerogenic activity (Açik et al. 2008).

Skin-Whitening Activity

The phytomedicine Belides (R) obtained from *B. perennis* flowers exhibited a strong inhibitory effect on melanogenesis (John et al. 2005). It was found to contain bioactive constituents such as saponins (triterpene glycosides), polyphenols and polysaccharides. Results of a comparative study conducted with Belides and arbutin, used at equivalent polyphenol concentrations, revealed that Belides was about twice as active as arbutin. Tests carried out on melanoma cells (B16V) showed that Belides controlled transcription of tyrosinase expression, thus inhibiting its synthesis. In addition,

Belides significantly decreased the release of the peptide hormone endothelin (ET-1), the binding capacity of alpha-MSH (melanocyte-stimulating hormone) on the melanocortin receptor-1 (MC1-R) and also melanosome uptake mechanisms. Further, results of a pilot study performed on human volunteers demonstrated the in-vivo skin-lightening efficacy of Belides. The authors, thus, recommended the use of Belides in skin-lightening cosmetics and for pigmentation disorders, hyperpigmentation or age spots.

Traditional Medicinal Uses

Since antiquity, *B. perennis* has been used as a diuretic, antispasmodic, antiinflammatory, astringent, antitussive, demulcent, digestive, emollient, expectorant, laxative, purgative, tonic, antipyretic, vulnerary, ophthalmic and homeostatic in traditional medicine (Grieve 1971; Launert 1981; Chiej 1984; Phillips and Foy 1992; Bown 1995; Duke et al. 2002). It has been traditionally used for wounds and was found useful in treating delicate and listless children. It has been used in folk medicine in the treatment of rheumatism and as an expectorant (Schöpke 1991). It has also been employed as a vulnerary and against ecchymoses in veterinary medicine (Avato and Tava 1995). Yazıcıoğlu and Tuzlacı (1995) reported that *B. perennis* was used to relieve stomach ache in Trabzon, Turkey and for treating breast cancer (Chiej 1984). The fresh or dried flowering heads are normally used in infusions, decoctions, ointments and poultices in the treatment of catarrh, rheumatism, arthritis, liver and kidney disorders as a blood purifier, etc. An ointment of the leaves has been applied externally to wounds, bruises and cuts and an aqueous extract used internally to treat inflammatory disorders of the liver. Chewing of leaves was said to cure oral ulcers. A strong decoction of the roots has been recommended for the treatment of scorbutic complaints and eczema, while a mild decoction has been used to ease complaints of the respiratory tract, rheumatic pains and painful or heavy menstruation. The herb has also been widely used in homeopathic therapy.

Other Uses

Bellis perennis is a popular ornamental, widely cultivated in gardens and parks. This daisy is widely steeped in magic and mythology; the daisy is used magically in spells for love and lust and thus associated with the goddess of love Venus (Roman), Aphrodite (Greek) and Freya (Norse). Daisies have traditionally been used for making daisy chains in children's games.

It was shown that the plant possessed antifungal activity *in vitro* and *in-vivo* against *Ceratocystis ulmi*, pathogen of Dutch elm disease (Desevedavy et al. 1989).

Comments

The plant may be propagated by seeds or division.

Welsh: Melyn Mari

Origin/Distribution

The species is a native of the Mediterranean area, but now *Calendula* has naturalized in many temperate countries and is cultivated as ornamentals in warm temperate and sub-temperate areas.

Agroecology

The plant grows well in full sun and tolerate most soils—acidic, sandy, loamy and clayey soils with pH 4.5–8.3—but does best on well-drained, moist, loamy soil. In temperate areas, seeds are sown in spring for blooms that last throughout the summer and well into the fall.

Edible Plant Parts and Uses

Flowers and leaves are edible (Hedrick 1972; Facciola 1990; Roberts 2000). Fresh petals are chopped and added to salads or used as garnish in dishes. The petals can be used in omelette, curry

and custard (Roberts 2000). Dried petals have a more intense flavour and are used as a seasoning in soups, cakes, drinks and baked products. An edible yellow dye is obtained from the flowers and used as colorant for butter, cheese, drinks, rice, soups, confectionery and baked products and also used as a substitute for saffron. Calendula was once known as 'poor man's saffron' as its extract was fed to hens to make their egg yolks golden. An herbal tea can be prepared from the flowers and petals. The leaves can be eaten raw in salads.

Botany

The plant is usually grown as an annual, erect or procumbent and branched, stipitate-glandular, with a strong tap root. Leaves are sessile or shortly petiolate, elliptic, obovate, oblong, oblanceolate to spatulate, 3–12 (–16 cm) by 2–5 cm, with entire margins, apex acute, base sometimes clasping, sparsely arachnose on both surfaces (Plates 1 and 2). Flower heads (capitula) borne singly; involucre campanulate to hemispheric; phyllaries linear-lanceolate, pubescent and in two series; ray florets 15–50 (>100) in 1–3 or more series, functionally female, with yellow to orange, linear to oblanceolate corolla; central disc florets 20–60 (>100), hermaphrodite but functionally male, tubular with campanulate throat, corolla yellow, orange (Plates 2 and 3), reddish or purplish. Achene curved and tuberculate or transversely ridged.

Nutritive/Medicinal Properties

Flower Phytochemicals

Carbohydrates

The water soluble polysaccharide fraction obtained from *C. officinalis* inflorescences were found to contain 84.58 % pectic substances, 29.25 % ash, 9.25 % moisture, 25.77 % acidic sugars, 31.25 % reducing sugars and 4.92 % proteins and to have the following monosaccharide composition comprising glucose, galactose, arabinose, xylose, rhamnose and galacturonic

Plate 1 Leaves and a flower bud

Plate 3 Close view of flower heads

Plate 2 Yellow flowers in bloom

acid (Chushenko et al. 1988). Three homogeneous polysaccharides were isolated from *Calendula officinalis* flowers (Varljen et al.

1989). All three polysaccharides contained a (1 → 3)-linked β -D-galactan backbone with branching points at C-6. The side chains are composed of short α -Araf(1 → 3)-Araf, α -L-Rhap-(1 → 3)-Araf or simple α -L-Araf units. The carbohydrate composition of *Calendula officinalis* consisted of free glucose and pectin substances with a low degree of esterification (Khodzhaeva and Turakhozhaev 1993). The monosaccharide composition of the stem comprised rhamnose, galactose and galacturonic acid and the inflorescences have rhamnose, galactose, glucose and galacturonic acid. Pectic substances were also found in the stems and inflorescences.

Terpenoids

From *Calendula officinalis* flowers, five glycosides of oleanolic acid were isolated and their structures established as 3-glucuronide; 3-(galactosyl-glucuronide); 3-(galactosyl-glucuronide); 17-glucoside; 3-(galactosyl-(glucosyl)-glucuronide); and 3-(galactosyl-(glucosyl)-glucuronide); 17-glucoside (Kasprzyk and Wojciechowski 1967). A number of alcohols representing different types of pentacyclic triterpenes were identified in *Calendula officinalis* flowers (Kasprzyk and Pyrek 1968). In the group of monohydroxy alcohols, the following were identified: α -amyirin, β -amyirin, taraxasterol and lupeol in addition to previously isolated ψ -taraxasterol. In the group of dihydroxy alcohols, the following were identified: brein and calenduladiol (a new diol of lupeol type) in addition to the previously isolated

arnidiol and faradiol. The presence of four other diols of the α -amyrin, β -amyrin and ψ -taraxasterol types was observed. Alcohols of ψ -taraxasterol type, possessing three and four hydroxyl groups, were also isolated as well as a small amount of oleanolic aldehyde. A new triterpene diol, ursodiol, was isolated from dry *Calendula officinalis* flowers (Sliwowski et al. 1973). Its structure was confirmed as 3,21-di-OH-ursa-12-en. Kasprzyk and Wiłkomirski (1973) isolated a triterpene triol of α -amyrin type from the flowers. A triterpene glycoside, calendulose F, was isolated from the flowers (Vidal Ollivier et al. 1988).

In *Calendula officinalis* flowers, triterpene monols were found mainly in the chromoplast fraction (68 % of total) with smaller amounts in the cell debris, microsomal and supernatant fractions; the mitochondrial fraction was almost devoid of these compounds (Adler and Kasprzyk 1976). Triterpene diols were present exclusively in the chromoplast fraction, 98 % in the form of the 3-monoesters and 2 % in the form of diesters. The data suggested that the hydroxylation of the triterpene monols to the corresponding diols proceeded in the chromoplasts and the esterified form of the monols was probably the substrate for this reaction.

From *Calendula officinalis* flowers, five pentacyclic triterpene trihydroxyalcohols were isolated and identified as olean-12-ene-3 β ,16 β ,28-triol, lup-20(29)ene-3 β ,16 β ,28-triol, tarax-20-ene-3 β ,16 β ,22 α -triol, tarax-20-ene-3 β ,16 β ,30-triol and ursa-12-ene 3 β ,16 β ,21-triol (Wiłkomirski 1985). Gracza (1987) identified the following terpenoids from the flowering heads: menthone, isomenthone, caryophyllene and an epoxide and ketone derivative, pedunculatine, α - and β -ionone, a β -ionone epoxide derivative and dihydroactinidiolide. Triterpenoids found in the flowers included faradiol monoester, monools ψ -taraxasterol, lupeol, taraxasterol and β -amyrin (Della Loggia et al. 1994). Eleven triterpene alcohols helianol, taraxasterol, ψ -taraxasterol, α -amyrin, β -amyrin, lupeol, taraxerol, cycloartenol, 24-methylenecycloartanol, tirucalla-7,24-dienol and dammaradienol were isolated from the tubular flowers of *Calendula officinalis*, *Carthamus tinctorius*, *Cosmos bipinnatus*, *Chrysanthemum morifolium*,

Helianthus annuus and *Matricaria matricarioides* (Akihisa et al. 1996). All the flowers shared a common characteristic feature by containing helianol as the most predominant component (29–86 %) in the triterpene alcohol fractions.

From the 1-butanol-soluble fraction of the methanol flower extract of *Calendula officinalis*, four new triterpene oligoglycosides, calendasaponins A, B, C and D, were isolated, together with eight known saponins, seven known flavonol glycosides and a known sesquiterpene glucoside (Yoshikawa et al. 2001). They also isolated two new ionone glucosides (officinosides A and B) and two sesquiterpene oligoglycosides (officinosides C and D) from the flowers of Egyptian *Calendula officinalis* (Marukami et al. 2001). One new triterpenoid of oleanane-series, cornulacic acid acetate (1), along with oleanolic acid acetate was isolated from *Calendula officinalis* flowers (Naved et al. 2005). The structure of (1) was established as 3 β -acetoxy-olean-12-en-27-oic acid and oleanolic acid acetate was characterized as 3 β -acetoxy-olean-12-en-28-oic acid.

Ten oleanane-type triterpene glycosides, 1–10, calendulaglycoside A (1), calendulaglycoside A 6'-O-n-methyl ester (2), calendulaglycoside A 6'-O-n-butyl ester (3), calendulaglycoside B (4), calendulaglycoside B 6'-O-n-butyl ester (5), calendulaglycoside C (6), calendulaglycoside C 6'-O-n-methyl ester (7), calendulaglycoside C 6'-O-n-butyl ester (8), calendulose F 6'-O-n-butyl ester (9) and calendulose G 6'-O-n-methyl ester (10), along with five known flavonol glycosides, 11–15 isorhamnetin-3-O-neohesperidoside, isorhamnetin-3-O-2-rhamnosyl rutinoside, isorhamnetin-3-O-rutinoside, quercetin-3-O-glucoside and quercetin-3-O-rutinoside, were isolated from the flowers of *Calendula officinalis* (Ukiya et al. 2006).

Lipids

Sterol esters as well triterpene monol and diol esters isolated *Calendula officinalis* flowers were found to contain as alcohol components all the types of sterols and triterpenic alcohols present in the plant (Wojciechowski et al. 1972). Sterols and triterpene monols were esterified with acetic, lauric, myristic and palmitic acids. Triterpene

diols were esterified with lauric, myristic and palmitic acids. The main diol esters were 3-monoesters; diesters were present only in very small amount.

In *C. officinalis* ligulate flowers, it was shown that all free and ester-bound sterols and triterpene monols in both forms occurred in the chromoplast fraction and in the chromoplast-free fraction, whereas all diols were localized only in the chromoplast fraction (Wilkomirski and Kasprzyk 1979). The compositions of the fatty acids esterifying monols and sterols were similar to those esterifying diols in the chromoplasts. However, the fatty acids esterifying extra-chromoplast monols and sterols were different. This result indicated triterpene monol esters to be substrates for the biosynthesis of 3-monoesters of diols. Faradiol esters, namely, faradiol-3-myristic acid ester, faradiol-3-palmitic acid ester and ψ -taraxasterol, were isolated from *C. officinalis* flower heads (Zitterl-Eglseer et al. 1997).

The main compounds of lipophilic extracts of flower heads of *Calendula officinalis* comprised triterpendiol esters, mainly faradiol laurate, faradiol myristate and faradiol palmitate (Zitterl-Eglseer et al. 2001). These faradiol-3-*O*-monoesters were quantified in different parts of *C. officinalis* plants, namely, ray florets, disc florets, involucre bracts, receptacles, leaves and seeds. The contents of the esters were highest in ray florets, approximately ten times lower in disc florets than in the ray florets, and approximately ten times lower in involucre bracts than in the disc florets. In the leaves only traces of the esters could be detected, and in the receptacles no esters could be detected at all. Quantification in the seed was not possible using this method because of interfering fatty compounds.

Dichloromethane extract of dried flowers of *Calendula officinalis* was found to contain eight known bioactive pentacyclic terpenoids and triterpendiol monoesters, namely, faradiol-3-*O*-palmitate, faradiol-3-*O*-myristate, faradiol-3-*O*-laurate, arnidiol-3-*O*-palmitate, arnidiol-3-*O*-myristate, arnidiol-3-*O*-laurate, calenduladiol-3-*O*-palmitate and calenduladiol-3-*O*-myristate (Neukirch et al. 2004). Of the ten varieties of *C. officinalis* investigated, calypso orange florensis

produced the highest amounts of the bioactive monoesters, followed by Fiesta Gitana Gelb and may orange florensis. The lipophilic extract from the flowers of calypso orange florensis variety also contained low levels of the newly characterized calenduladiol-3-*O*-laurate.

Marigold also has oleoresins. The solubility of Marigold (*Calendula officinalis*) oleoresin in supercritical CO₂ (SC-CO₂) varied from 4.74×10^{-4} to 17.04×10^{-4} g oleoresin/g CO₂ (Danielski et al. 2007). The use of palm oil as cosolvent for SC-CO₂ extraction of Marigold flower was found to enhance the yield of lutein fatty acid esters by approximately 16 %, with the most suitable concentration being 10 % w/v palm oil (Palumpitag et al. 2011). Under this condition, approximately 87.2 % recovery of lutein fatty acid esters was obtained after 4 hours extraction at 60 °C and 40 MPa. Furthermore, saponification of the Marigold oleoresin for 3 hours with 2 ml of 40 % (w/v) KOH solution per 1 g of oleoresin resulted in the maximum conversion of lutein esters, giving approximately 157.24.4 mg of free lutein/g oleoresin.

Carotenoids

The carotenoid content was higher in orange varieties of *C. officinalis*: 276 mg/100 g fresh flowers for Double Esterel Orange variety and 111 mg/100 g fresh flowers for Radio Extra variety (Pintea et al. 2003). All varieties contain the same pigments (xanthophylls) but there were significant differences for the ratio between individual pigments. The main pigments identified were flavoxanthin, lutein, rubixanthin, β -carotene, γ -carotene and lycopene. The great majority of xanthophylls present had a β - ϵ structure: flavoxanthin, lutein and luteoxanthin. Zeaxanthin (3,3'-dihydroxy- β , β -carotene) was present in small amount, as well as their epoxides: antheraxanthin, mutatoxanthin and auroxanthin. Other carotenoids present included neoxanthin, lactucaxanthin and α -carotene. Orange varieties contained higher amounts of hydrocarbons, 44.5 % of total carotenoid in Double Esterel Orange, while yellow varieties contain mostly oxygenated derivatives, 97 % of total carotenoids in Double Esterel Jaune. In the orange varieties, a

preferential biosynthesis of hydrocarbons with ψ - ψ and β - ψ structure and of monoxanthophylls with β - ψ (or α - ψ) structure was noted.

In the petals and pollens of *Calendula officinalis*, the main carotenoids were flavoxanthin and auroxanthin while the stem and leaves mostly contained lutein and β -carotene (Bakó et al. 2002).

Carotenoids present in *C. officinalis* cv Alice Orange flowers in percent of total carotenoids (Kishimoto et al. 2005) and in $\mu\text{g/g}$ fresh weight (Kishimoto et al. 2007) were respectively (8'R)-luteoxanthine 11 % 186.6 μg ; lutein-5,6-epoxide 1.6 % 27.1 μg ; (8R)-lutein-5,8-epoxide (flavoxanthin) 28.5 %, 483.4 μg ; (8R,8'R)-auroxanthin 7.1 %, 120.4 μg ; (9'Z)-lutein-5,6-epoxide 5 %, 84.8 μg ; lutein 2 % 33.9 μg ; antheraxanthin 1 % 17.0 μg ; (9Z)-lutein 0.6 %, 10.2 μg ; (5'Z,9'Z)-rubixanthin 4 %, 67.8 μg ; α -carotene 0.8 %, 13.6 μg ; β -carotene 3.4 %, 57.7 μg ; (5'Z)-rubixanthin 3 %, 50.9 μg ; δ -carotene 1.4 %, 23.7 μg ; (5Z,9Z,5'Z,9'Z)-lycopene 4.1 %, 69.5 μg ; γ -carotene 2 %, 33.9 μg ; (5'Z)- γ -carotene 4.4 %, 74.6 μg ; (5Z,9Z,5'Z)-lycopene 3.5 %, 59.4 μg ; (5Z,9Z)-lycopene 4.1 %, 69.5 μg and (all - E)-lycopene 8.7 %, 147.6 μg . The carotenoid composition in Alice Yellow flowers were (8'R)-luteoxanthin 15.6 %, 195 μg ; lutein-5-6-epoxide 3.2 %, 40 μg ; (8R)-lutein-5,8-epoxide (flavoxanthin) 42.6 %, 532.5 μg ; (8R,8'R)-auroxanthin 10.7 %, 133.7 μg ; (9'Z)-lutein-5,6-epoxide 8.5 %, 106.2 μg ; lutein 5 %, 62.5 μg ; antheraxanthin 2.5 %, 31.2 μg ; (9Z)-lutein 1.5 %, 18.7 μg ; and β -carotene 1.0 %, 12.5 μg . Total carotenoids in *C. officinalis* Alice orange was 1696.2 $\mu\text{g/g}$ FW comprising 963.4 μg of yellowish carotenoids and 668.3 μg of reddish carotenoids and total carotenoids in Alice yellow was 1249.9 $\mu\text{g/g}$ FW comprising 119.9 μg of yellowish carotenoids and 1.2 μg of reddish carotenoids (Kishimoto et al. 2007).

Studies showed that solvent had an influence on the stability of carotenoids in oil extracts of *Calendula officinalis* (Bezbradica et al. 2005). The highest degradation rates were observed in extracts prepared with linoleic acid-rich solvents (sunflower oil, soybean oil and grape seed oil), while the lowest were found in oil with saturated

fatty acids (Myritol 312®) and paraffin oil. Studies showed that saline irrigation water decreased the fresh and dry weights of *Calendula officinalis* flower heads and pigment contents (total flavonoids and total carotenoids) but increased essential oil yield and its main components (α -cadinol, γ - and δ -cadinene) (Khalid and da Silva 2010). Fresh and dry weights of flower heads and essential oil increased towards the full bloom stage of flowering while pigment content, such as total flavonoids and total carotenoids, increased.

Flavonoids

Eight flavonoids were isolated from *C. officinalis* inflorescence: two aglycones (quercetin, isorhamnetin) and six glycosides (isoquercetin, isorhamnetin 3-O- β -D-glucoside, narcissin, calendoflaside, calendoflavoside and calendoflavobioside) (Komissarenko et al. 1988). Seven flavonol 3-O-glycosides were isolated from the flowers of *Calendula officinalis* and elucidated as isorhamnetin 3-O-glucoside, rutinoid, neo-hesperidoside, quercetin glucoside and 2 (G)-rhamnosylrutinoside (Vidal-Ollivier et al. 1989). Bilia et al. (2001) identified narcissin, rutin, isoquercitrin, quercetin-3-O-rutinosylrhamnoside, isorhamnetin-3-O-rutinosylrhamnoside, isorhamnetin-3-O-glucosylglucoside and isorhamnetin-3-O-glucoside in *C. officinalis* flowers. The triglycoside isorhamnetin-3-O- α -L-rhamnopyranosyl-(1 \rightarrow 2)-O-[α -L-rhamnopyranosyl-(1 \rightarrow 6)]- β -D-glucopyranoside together with the already known glycosides isorhamnetin-3-O- β -D-glucopyranoside and isorhamnetin-3-O- α -L-rhamnopyranosyl-(1 \rightarrow 6)-O- β -D-glucopyranoside (narcissin) was isolated from *Calendula officinalis* flowers (Masterova et al. 1991). The total content of flavonoids in ligulate ray florets and tubular discflorets inclusively involucre was found to be 0.88 and 0.25 %, respectively.

The following flavonoids isorhamnetin (3'-methoxy-4',3,5,7-tetrahydroxyflavone), isorhamnetin-3-O-glucoside, rutin, quercetin glucoside, quercetin-neohesperoside and quercetin-2G-rhamnosil-rutinoside were isolated from flowers and found to have good antioxidant activity (Albulescu et al. 2004). Two flavonoids

were isolated from the flowers and identified as isorhamnetin 3-*O*-rutinoside (narcissin) quercetin 3-*O*- β -D-glucopyranoside (isoquercitrin) (Kurkin and Sharova 2007). Patulitrin (1) and patuletin (2) were found only in Marigold flowers during and after flowering (Guinot et al. 2008). A water-ethanol mixture gave a high extraction efficiency of both flavonoids.

Essential Oil

Crabas et al. (2003) reported that the essential oil of *Calendula officinalis* obtained from dried flowers in Italy contained methyl hexadecanoate (23.8 %), methyl linoleate (18.6 %), methyl 9,12,15-octadecatrienoate (17.2 %), methyl octadecanoate (4.8 %), methyl tetradecanoate (4.6 %), g-cadinene and cubenol (4.0 %), d-cadinene (3.2 %), a-cadinol (1.8 %) and oplopanone (1.3 %). Essential oil constituents of *C. officinalis* flower head (French source) and Slovakian source without fertilizer application, respectively, were β -pinene 0.45 %, 0.38 %, α -pinene 2.47 %, 2.18 %, myrcene 0.19 %, 0.29 %, phellandrene 2.76 %, 0.74 %, *p*-cymene 2.76 %, 2.22 %, limonene 19.16 %, 18.28 %, 19.61 %, terpinene 0.98 %, 1.578 %, caryophyllene 0.96 %, 1.06 %, 1,18cineole 0.47 %, 0.66 %, linalool 20.88 %, linalyl acetate 36.5 %, 38.64 %, camphor 1.98 %, 5.63 %, borneol 0.96 %, 1.84 %, carvone 0.43 %, 2.54 %, geraniol 2.66 %, 1.9 %, geranyl acetate 0.17 %, 0.17 % and caryophyllene oxide 0.44 %, 1.05 % (Naguib et al. 2005). In another study, essential oil constituents from *Calendula officinalis* flowers from steam distillation were identified as α -copaene 0.9 %, α -ionone 1.5 %, α -humulene 1.2 %, geranylacetone 1.6 %, γ -muurolene 2.3 %, β -ionone 3.2 %, ledene 2.3 %, α -muurolene 5.6 %, γ -cadinene 8.9 %, δ -cadinene 22.5 %, α -cadinene 0.9 %, α -calacorene 2.3 %, caryophyllene oxide 0.5 %, copaene-4- α -ol 0.6 %, β -oplopanone 1.7 %, viridiflorol 2.2 %, ledol 1.3 %, 1,10-di-epi-cubenol 1.6 %, epi- α -muurolol 12.9 %, α -cadinol 20.4 % and cadalene 0.8 % (Gazim et al. 2008). Volatile constituents from *Calendula officinalis* flowers from headspace solid-phase microextraction were β -cyclocitral 2.1 %, α -cubebene 1.8 %, α -copaene 15.1 %, β -cubebene 1.8 %, α -gurjunene

2.7 %, β -caryophyllene 2.7 %, α -ionone 2.3 %, α -humulene 3.9 %, γ -muurolene 5.3 %, β -ionone 3.9 %, α -muurolene 6.2 %, γ -cadinene 25.5 %, δ -cadinene 22.1 % and α -cadinene 2.3 % (Gazim et al. 2008). Volatile constituents from *Calendula officinalis* flowers from headspace cold finger extraction were α -copaene 18.4 %, β -cubebene 3.7 %, α -gurjunene 4.2 %, β -caryophyllene 8.6 %, α -humulene 3.9 %, γ -muurolene 4.7 %, α -muurolene 5.8 %, γ -cadinene 24.9 %, δ -cadinene 18.6 % and α -cadinene 2.3 % (Gazim et al. 2008).

Twenty-four compounds were identified in the fresh flower oil of *C. officinalis*, and the yield was 0.09 % (Okoh et al. 2008). Sesquiterpenoids dominated the fresh flower oil. Major components of the fresh flower oil were α -thujene (26.9 %), T-muurolol (24.9 %) and δ -cadinene (13.1 %).

Coumarins

The ethanol extract of the flowers was found to contain coumarins—scopoletin, umbelliferone and esculetin (Derkach et al. 1987).

Terpenoids, Flavonoids and Phenolic Acids

Triterpenoid esters purified from *C. officinalis* flower heads included faradiol-3-*O*-laurate, faradiol-3-*O*-myristate and faradiol-3-*O*-palmitate (Hamburguer et al. 2003). Accompanying minor compounds of the triterpene ester fraction purified included maniladiol 3-*O*-laurate, maniladiol-3-*O*-myristate, ψ -taraxasterol and β -amyrin. Oleanolic acid, β -amyrin, β -amyrin acetate, rutin, narcissin, 3-glucoside of isorhamnetin, quercetin, isoquercitrin, vanillic acid, caffeic acid, chlorogenic acid, protocatechuic acid, *p*-coumaric acid and syringic acid were identified in the flower extract (Matysik et al. 2005). Ten oleanane-type triterpene glycosides were isolated from the flowers: calendulaglycoside A (1), calendulaglycoside A 6'-*O*-*n*-methyl ester (2), calendulaglycoside A 6'-*O*-*n*-butyl ester (3), calendulaglycoside B (4), calendulaglycoside B 6'-*O*-*n*-butyl ester (5), calendulaglycoside C (6), calendulaglycoside C 6'-*O*-*n*-methyl ester (7), calendulaglycoside C 6'-*O*-*n*-butyl ester (8), calenduloside F 6'-*O*-*n*-butyl ester (9) and

calendulose G 6'-*O*-*n*-methyl ester (10) (Ukiya et al. 2006).

Miscellaneous Phytochemicals

Eighteen *n*-paraffins ranging from C₁₈ to C₃₅ were detected in the petals of *Calendula officinalis* (Komae and Hayashi 1971). The flowers also contained the bitter principle loliolide (calendin) (Willuhn and Westhaus (1987) and a tasteless yellow substance calendulin discovered by Geiger in 1819 (Shoemaker 1891).

Seed Phytochemicals

Fatty acid composition of the seed oil revealed the presence of lauric (3.90 %), myristic (3.58 %), palmitic (14.96 %), stearic (10.13 %), palmitoleic (4.55 %), oleic (16.26 %), linoleic (39.45 %) and linolenic (7.15 %) acids (Saleem et al. 1986). In the seed oil, conjugated acid was present to the extent of 4.5 % whereas the percentage of non-conjugated acid (linolenic acid) was only 2.65 %. The residual meal after the extraction of oil was also studied for its proteins (18 %) and amino acids composition.

The amounts (%) of lipids in *C. officinalis* seeds were: neutral lipids, 15.7 %; glycolipids (GLs), 0.9 %; and phospholipids (PhLs), 0.6 % (Ul'chenko et al. 1998). The lipid yield of extracts from the flowers (EF) was 17.1 % and from the leaves (EL) 9.3 %. The following classes of lipids were found (% by weight) hydrocarbons, 0.9 %; esters of sterols and triterpenols with fatty acids, 0.5 %; triacylglycerols (TAGs), 20.0 % comprising TAGs-I, 59.0; TAGs, 2–11.8 %; TAGs, 3–4.3 %; free fatty acids, trace; hydroxy-TAGs, 0.8 %; free sterols and free triterpenols, 0.4 %; diacylglycerols and monoacylglycerols, 1.2 %; and unidentified components, 1.1 %. The phospholipid complex of Marigold seeds consisted of eight classes, which may be arranged in order of content by weight as follows: PCs (phosphatidylcholines) > PIs (phosphatidylinositols) > *N*-acyl-PEs (*N*-acyl phosphatidylethanolamines) > *N*-acyl-lyso-PEs (*N*-acyl-lyso-phosphatidylethanolamines) > lyso-PIs (lyso-phosphatidylinositols) > PSs

(phosphatidylserines) > lyso-PCs (lyso-phosphatidylcholines) > PEs (phosphatidylethanolamines). The glycolipids of the seeds were represented by four components forming the following sequence by mass content: SGs (steryl-glycosides) > ESGs (ester steryl-glycosides) > MGDGs (monogalactosyldiacylglycerols) > DGDGs (digalactosyldiacylglycerols).

The lipid content of seed of 11 genotypes varied between 13.6 and 21.7 g oil/100 g seeds (Dulf et al. 2013). PUFA contents varied between 60.4 and 66.4 %, while saturates comprising mainly palmitic and long chain saturated fatty acids were found in higher amounts in sterol esters (49.3–55.7 % of total fatty acids). Calendic acid [18:3 (8*t*, 10*t*, 12*c*) (*n*–6)] with contents of 51.47–57.63 % of total fatty acids was the predominant polyunsaturated fatty acid (PUFA) followed by linoleic acid [18:2 (*n*–6)] (28.50–31.86 %), oleic acid [18:1 (*n*–9)] (4.44–6.25 %) and palmitic acid (16:0) (3.86–4.55 %). Small and very small (or trace) amounts (<2 %) of stearic (18:0), β-calendic [18:3 (8*t*, 10*t*, 12*t*) (*n*–6)], elaidic [18:1 (9*t*) (*n*–9)], arachidic (20:0), behenic (22:0), gondoic [20:1 (*n*–9)], α-linolenic [18:3 (*n*–3)], linoelaidic [18:2 (9*t*, 12*t*) (*n*–6)], *cis*-7-hexadecenoic [16:1 (*n*–9)], palmitoleic [16:1 (*n*–7)], lauric (12:0), myristic (14:0), pentadecanoic (15:0) and margaric (17:0) acids were also present. Cromack and Smith (1998) reported the seed oil content of around 20 %, of which up to 60 % was calendic acid, a useful industrial feedstock. Chisholm and Hopkins (1967) reported that *Calendula* could accumulate more than 40 % of calendic acid. Ozgul-Yucel found that Turkish calendula seed oil was characterized by high concentration of linoleic acid (43.5 %) and low content of CLNAs (calendic acid (18.3 %) + β-calendic (11.2 %)). Angelini et al. (1997) reported 16–46 % levels of calendic acid in the Italian Pot Marigold seed oils.

Crombie and Holloway (1985) found that linoleic and oleic acids were precursors in the biosynthesis of calendic acid in Marigold (*C. officinalis*) seeds but not linolenic acid. (9*S*)-Hydroxyoctadeca-(10*E*, 12*Z*)-dienoic acid (α-dimorphecolic acid) was isolated and converted into (*R/S*)-hydroxy- and -hydroperoxy-[9-3*H*]

octadeca-(10*E*,12*Z*)-dienoic acids but neither labelled specimen was converted into calendic acid by Marigold seed homogenate. Also α -dimorphecolic acid, a minor component of Marigold seed oil, was found to be a terminus rather than an intermediate for calendic acid.

Plant and Leaf Phytochemicals

In the flowers, stem and leaves of *C. officinalis*, 15 amino acids were detected in the free state: alanine, arginine, aspartic acid, asparagine, valine, histidine, glutamic acid, leucine, lysine, proline, serine, tyrosine, threonine, methionine and phenylalanine (Absavoa et al. 1994). Among them, six predominated: arginine, proline, glutamic acid, phenylalanine, lysine and leucine. The leaves contained about 5 % of amino acids, the stems 3.5 % and the flowers 4.5 %. Szakiel et al. (2005) found that Marigold (*C. officinalis*) synthesized significant amounts of oleanane saponins, found not only in flowers but also in all organs of plant. These glycosides comprised two series of structurally related compounds, that is, derivatives of 3-*O*-monoglucoside of oleanolic acid (hence named 'glucosides') and derivatives of 3-*O*-monoglucuronide ('glucuronides'), depending on the first sugar moiety linked to the C-3 hydroxyl group of oleanolic acid, which is either glucose or glucuronic acid. The occurrence of both series of oleanolic acid glycosides occurring in *C. officinalis* was earlier reported by Kasprzyk and Wojciechowski (1967) and Wojciechowski et al. (1971). 'Glucuronides', known as the series I, were designated with letters (F, D, D2, C, B, A) and 'glucosides', forming the series II—with Roman numerals from I to VIII. 'Glucuronides' were found in relatively large amounts (up to 2 % of the dry mass) in flowers and in considerably lower quantity in green organs of the plant. Ruszkowski et al. (2003) found 'glucuronides' in roots of young Marigold plants, while 'glucosides' accumulated mainly in roots of grown and senescing plants and also found in green organs of the plant. However, only glycosides I, II, III, VI and VII were found in Marigold shoots. Oleanolic acid

and its 3-*O*-glucuronide derivatives and 3-*O*-glucoside derivatives were found in vacuoles prepared from protoplasts and cell walls obtained from leaf cells of *Calendula officinalis* (Szakiel and Kasprzyk 1989). In both cell compartments 37 % of total cellular oleanolic acid accumulated, 0.6 % occurring as free oleanolic acid (only in vacuoles). Glucuronides accounted for 31.1 % (20.7 % in vacuoles and 10.4 % in cell walls) and glucosides for 5.3 % (2.6 % in vacuoles and 2.7 % in cell walls). Szakiel et al. (1995) found that [3-3*H*]oleanolic acid glycosides formed in the cytosol of *C. officinalis* leaf cells were transported to the extracellular space in the form of pentaglycoside VI (44 %), whereas glucuronides derived from [3-3*H*]oleanolic acid 3-*O*-monoglucuronide (29 %) as well as a part of glucosides (24 %) were transported into the cell walls.

Studies confirmed that plastoquinone occurred only in the chloroplasts, ubiquinone only in the mitochondria and α -tocopherol in both these subfractions of *C. officinalis* leaves (Janiszowska et al. 1976). In *Calendula officinalis* leaves the cyclization of squalene to β -amyryn and its further oxidation to oleanolic acid as well as the biosynthesis of all derivatives of oleanolic acid 3-glucoside and some derivatives of oleanolic acid 3-glucuronoside were found to occur in the microsomal fraction (Janiszowska and Kasprzyk 1977). The final metabolites of oleanolic acid 3-glucoside series, that is, pentaglycosides, were translocated from this fraction, one to the cell wall and plasma-lemma fraction and the other to the cytosol. The derivatives of oleanolic acid 3-glucuronoside were synthesized partially in other fractions and accumulated in the different membranous structures of the cell.

Polyphenolic compounds (g/kg dry matter) in the aerial Marigold plant parts were determined as follows: chlorogenic acid 0.55 g, 3,5-DCQA (dicafeoylquinic acid) 0.78, total caffeoyl derivatives 1.33 g, total dihydroxycinnamic acid derivatives 7.54 g, total flavonoids 5.12 g, total dihydroxycinnamic acid derivatives+flavonoids 12.66 g and total polyphenolic compounds 24.97 g (Fraisie et al. 2011).

Fatty acids C12–C22 were found to be components of acylated steryl glucosides in *Calendula officinalis* (Zdzislaw et al. 1975). As a source of acyl groups for the synthesis of steryl acylglucosides, various phospholipids obtained from the same plant were utilized in the following sequence: phosphatidylinositol greater than phosphatidylethanolamine greater than phosphatidylcholine. It does not utilize triacylglycerols and monogalactosyldiacylglycerols.

In 3-day and 14-day-old seedlings and leaves of *Calendula officinalis*, the following sterols were identified: cholestanol, campestanol, stigmastanol, cholest-7-en-3- β -ol, 24-methylcholest-7-en-3- β -ol, stigmast-7-en-3- β -ol, cholesterol, campesterol, sitosterol, 24-methylcholesta-5,22-dien-3- β -ol, 24-methylenecholesterol, stigmast-erol and clerosterol (Adler and Kasprzyk 1975). Sitosterol was predominant in young and stigmast-erol in old tissues. Young tissues contained relatively more campesterol, but in old tissues a C₂₈ $\Delta^{5,22}$ diene was present suggesting transformation of campesterol to its $\Delta^{5,22}$ analog, similar to that of sitosterol to stigmast-erol. All the identified sterols were present as free compounds and also in the steryl esters, glucosides, acylated glucosides and water-soluble complexes.

Petroleum ether extract of *Calendula officinalis* leaf showed the presence of fatty acids, and chloroform extracts showed the presence of triterpenes and sterols (Chakraborty 2010). Flavonoids, carbohydrates, amino acids, and saponins were present in methanol extract, and saponins, phenolic substances, and tannins were present in the water extract of *Calendula officinalis*.

Thirty and twenty-one compounds were identified in the fresh leaf and dry leaf oils of *C. officinalis* and the yield was 0.06 and 0.03 %, respectively (Okoh et al. 2008). Sesquiterpenoids dominated the fresh leaves (59.5 %) while the monoterpenes dominated the oil in the dry leaves (70.3 %). The fresh leaf oil was dominated by T-muurolol (40.9 %), α -thujene (19.2 %) and δ -cadinene (11.4 %), while the dry leaves oil was

found to be rich in 1,8-cineole (29.4 %), γ -terpinene (11.6 %), δ -cadinene (9.0 %), β -pinene (6.9 %) and α -thujene (6.3 %).

The yield in *Calendula officinalis* leaf essential oil showed a maximum at the full flowering stage (0.97 %) and a minimum during the pre-flowering stage (0.13 %) (Okoh et al. 2007). The compositions also showed different patterns at different phases of the vegetative cycle. Sesquiterpenes (α -cadinene, α -cadinol, T-muurolol and epi-bicyclosquiphellandrene) and monoterpenes (limonene, 1,8-cineole and *trans*- β -ocimene) showed the highest correlations with the age of the plant. Aiming the use of essential oil as a food ingredient, the most interesting stage is the post-flowering period, the essential oil at this time being rich in α -cadinene, α -cadinol, t-muurolol, limonene and 1,8-cineole, with *p*-cymene present at lower levels. The total yields of the essential oils at the different stages of the vegetative cycle increased with the age of the plant and ranged between 0.13 % (3rd week) and 0.97 % (12th week, flowering); α -cadinene is an important flavouring agent in baked foods, candy and chewing gum and also used as a fragrance in cosmetics and detergents. T-muurolol and α -cadinol are important antimicrobial agents. The essential oil at 12 week was dominated by geraniol (44.5 %), α -cadinol (24.20 %), δ -cadinene (23.8 %), T-muurolol (22.50 %), 1,8-cineole (22.10 %), cadina-1,4-diene (12.20 %), germacrene D (11.50 %), α -cadinene (10.7 %) and calarene (5.70 %). Other minor components included α -pinene (2.90 %), limonene (2.6 %), α -cubebene (1.7 %), α -humulene (1.7 %), β -pinene (1.4 %), nerolidol (1.3 %), sabinene (0.9 %), endobourbonene (1.0 %), β -caryophyllene (0.9 %), α -ylangene (0.8 %), palustron (0.7 %), epi-bicyclosquiphellandrene (0.5 %), β -selinene (0.3 %), alloaromadendrene (0.2 %), α -bourbonene (0.2 %), muurolene (0.10 %), terpene-4-ol (0.10 %), *p*-cymene (0.10 %), carvacrol (0.10 %), α -thujene (0.10 %) and α -gurjunene (0.10 %). These compounds occurred in trace amounts: δ -3-carene, nonanal, 3-cyclohexene-1-ol, α -phellandrene, bornyl acetate, sabinyl acetate, α -copaene, β -cubebene, aromadendrene and oplophenone.

Root Phytochemicals

A new series of glycosides of oleanolic acid was found in the roots of old *Calendula officinalis* plants (Wojciechowski et al. 1971). These compounds were derivatives of 3-glucoside of oleanolic acid and were different, from those previously isolated from the flowers, derivatives of 3-glucuronoside of oleanolic acid. The sugar components of eight representatives of the new series are glucose and galactose in following ratios: in glucoside I, 1:0; in II, 1:1; in III, 1:2; in IV, 2:1; in V, 3:1; in VI, 3:2; in VII, 4:1; and in VIII, 4:1. The sugars in I–VII were attached only in position 3 of oleanolic acid, but in VIII one glucose molecule was joined to 28-carboxyl of oleanolic acid. Glucoside I was identified as 3-monoglucoside and II as 3-(4'-galactosyl)-glucoside of oleanolic acid. Besides these compounds, 6'-methyl ester of 3-glucuronoside of oleanolic acid was also found in the roots.

A monoside 3-*O*- β -D-glucopyranoside of oleanic acid and a bioside (calenduloside A) with the structure 3-galactosylglucosyloleanolic acid (Vecherko et al. 1969, 1971b) and calenduloside B with the structure *O*- β -D-galactopyranosyl-(1 \rightarrow 4)-*O*- β -D-glucopyranosyl-(1 \rightarrow 3)-oleanoloyl-(28 \rightarrow 1)- α -D-glucopyranoside (Vecherko et al. 1971a); oleanolic acid 3-[[galactopyranosido-(1 \rightarrow 3)] [glucopyranosido-(1 \rightarrow 2)]- β -D-glucopyranoside} (calenduloside C) and 28-acyl- β -D-glucopyranoside of calenduloside C (calenduloside D) (Vecherko et al. 1975); glucopyranosyl oleanolate 3-*O*- β -D-glucuronopyranoside (calenduloside F) (Vecherko et al. 1973), oleanolic acid 3-*O*- β -D-galactopyranosyl-(1 \rightarrow 3)- β -D-glucuronoside (calenduloside G) and 28-acyl- β -D-glucopyranoside of calenduloside G (calenduloside H) (Vecherko et al. 1974) were isolated from the roots of *C. officinalis*. Calenduloside B, triside of oleanolic acid, was isolated from the roots (Iatsyno et al. 1978).

Chemical studies have revealed the presence of various classes of compounds, the main being triterpenoids, flavonoids, coumarins, quinones, volatile oil, carotenoids and amino acids in *C. officinalis* plant parts (Muley et al. 2009; Khalid and da Silva 2012). The extract of this

plant as well as pure compounds isolated from it had been demonstrated to possess multifold pharmacological activities: antioxidant, anti-inflammatory, antiedematous, immunostimulant, anticancer, lymphocyte and wound healing, hepatoprotective, antibacterial and antifungal, anti-HIV, spasmolytic and spasmogenic, cytotoxic, genotoxic and antigenotoxic, inhibition of heart rate and antiviral, among others.

Antioxidant Activity

Superoxide radicals and hydroxyl radicals were observed in decreasing concentrations in the presence of increasing concentrations of *C. officinalis* butanolic fraction with IC₅₀ values of 1 and 0.5 mg/ml, respectively, suggesting a possible free radical scavenging effect (Cordova et al. 2002). Lipid peroxidation in liver microsomes induced by Fe²⁺/ascorbate was 100 % inhibited by 0.5 mg/ml of the fraction (IC₅₀=0.15 mg/ml). Its total reactive antioxidant potential (TRAP) (in μ M Trolox equivalents) was 368.14 and its total antioxidant reactivity (TAR) was calculated to be 249.19 μ M. The results suggested the butanolic fraction of *C. officinalis* to have significant free radical scavenging and antioxidant activity.

The methanol and water extracts of wild Marigold, *Calendula arvensis* (GWM) and cultivated Marigold, *Calendula officinalis* (CM), in a concentration range of 0.10–0.90 mg/ml, scavenged all types of investigated radicals in dependence on their applied concentrations (Ćetković et al. 2004). Generally, CM extracts possessed higher scavenging and antioxidant activity than GWM extracts, while methanol extracts exhibited lower activities than water extracts. Water extracts of CM had the best antioxidant properties; 0.75 mg/ml extracts completely eliminated hydroxyl radical, which was generated in the Fenton system. The same concentration of this extract scavenged 92 % DPPH and 95 % peroxyl radical during lipid peroxidation. Antioxidant properties were in correlation with the contents of total phenolic compounds (14.49–57.47 mg/g) and flavonoids (5.26–18.62 mg/g) in extracts. The electron spin

resonance (ESR) spectroscopy data demonstrated that methanol and water extracts of CM possessed similar free radicals scavenging and anti-oxidative activity as synthetic antioxidants BHA. Total antioxidant capacity (%) (DPPH scavenging activity) of *C. officinalis* aerial plant parts was 1.52 % and contribution from the main caffeoyl derivatives was as follows: chlorogenic acid 3.15 %, 3,5-DCQA (dicaffeoylquinic acid) 6.90 % and total caffeoyl derivatives 10.05 % (Fraisie et al. 2011).

Calendula officinalis flower top extract was found to scavenge superoxide radicals generated by photoreduction of riboflavin and hydroxyl radicals generated by Fenton reaction and inhibited in-vitro lipid peroxidation (Preethi et al. 2006). Concentrations needed for 50 % inhibition (IC_{50}) were 500, 480 and 2,000 mg/ml, respectively. The extract scavenged ABTS radicals and DPPH radicals with IC_{50} of 6.5 and 100 mg/ml, respectively. The extract also scavenged nitric oxide (IC_{50} = 575 mg/ml). Oral administration of *Calendula* extract inhibited superoxide generation in macrophages in vivo by 12.6 and 38.7 % at doses of 100 and 250 mg/kg body weight. Oral administration of the extract to mice for 1 month significantly increased catalase activity and produced significant increase in glutathione levels in the blood and liver. Glutathione reductase was found to be increased, whereas glutathione peroxidase was found to be decreased after extract administration. The results indicated *Calendula officinalis* possessed significant antioxidant activity in-vitro and in-vivo.

The propylene glycol extract of *Calendula officinalis* exerted its anti-ROS (reactive oxygen species) and anti-RNS (reactive nitrogen species) activity in a concentration-dependent manner during polymorphonuclear leukocytes burst, with significant effects being observed at even very low concentrations: 0.20 μ g/ml without L-arginine, 0.10 μ g/ml when L-arginine was added to the test with phorbol 12-myristate 13-acetate and 0.05 μ g/ml when it was added to the test with *N*-formyl-methionyl-leucyl-phenylalanine (Braga et al. 2009). Electron paramagnetic resonance (EPR) spectroscopy confirmed these findings, 0.20 μ g/ml being the

lowest concentration of *C. officinalis* extract that significantly reduced 2,2-diphenyl-1-picrylhydrazyl (DPPH). *Calendula officinalis* propylene glycol extracts were found to have protective effect against oxidative DNA damage and lipid peroxidation induced by high polyunsaturated fatty acid (PUFA) intake in young growing pigs (Frankic et al. 2009). It elicited a numerical trend towards the reduction of plasma malondialdehyde and urinary isoprostane (iPF2 α -VI) excretion. Its effect was comparable with that of vitamin E. The extract from flower tops showed less antioxidant potential than the extract from petals. They concluded that the amount of *C. officinalis* extracts proposed for internal use by traditional medicine protected the organism against DNA damage induced by high PUFA intake.

Methanol enabled more efficient extraction of flavonoids from *C. officinalis* flowers than the other solvents isopropanol and ethanol tested (Butnariu and Coradini 2012). From cv Petran and cv Plamen flowers, methanol extracted, respectively, 2.04 and 2.142 mg/100 g FW of carotene pigments (lycopene, lutein), 10.358 and 5.222 mg/100 g FW of total photosynthetic pigments (chlorophyll a, b), total flavonoid content 96.17 and 90.37 mg quercetin equivalent (QE)/100 ml and total phenolic content of 134 and 153.23 mg GAE/100 ml. The highest antioxidant activity correlated to the polyphenol content was obtained for extracts prepared using methanol. For the methanol extract of cv Petran and cv Plamen, the DPPH radical scavenging activity was 2.64 and 2.97 mmol Trolox/g and the ferric reducing antioxidant power (FRAP) was 0.29 and 1.55 mmol Fe²⁺/g.

Studies by Ozkol et al. (2012) showed that administration of *Calendula officinalis* extract protected rats against subacute cigarette smoke-induced cell injury. Marigold extract decreased the elevated levels of malondialdehyde, reduced glutathione and protein carbonyl caused by cigarette smoke. Further, Marigold extract increased the diminished levels of glutathione peroxidase (GPx), superoxide dismutase activities and β -carotene and vitamins A and C caused by cigarette smoke.

Bernatoniene et al. (2011) confirmed dry *Calendula officinalis* extract to be an effective scavenger of H_2O_2 radicals in in-vitro studies with the mitochondria of rat cardiac muscles. *Calendula* extract incorporated into hydrophilic cream containing complex emulsifier provided significant antioxidant effect due to the content of carotenoids, polyphenols and flavonoids and good emulsion quality. Cream with the best properties (0.9 % of *Calendula* extract) contained 0.73 mg/100 g of total carotenoids expressed as β -carotene.

Anticancer/Antiproliferative Activities

Laser Activated Calendula Extract (LACE) showed a potent in-vitro inhibition (70–100 %) of tumour cell proliferation when tested on a wide variety of human (leukaemias, melanomas, fibrosarcomas and cancers of the breast, prostate, cervix, lung, pancreas and colorectal) and murine tumour cell lines (Jiménez-Medina et al. 2006). Mechanisms of inhibition were identified as cell cycle arrest in G0/G1 phase and caspase-3-induced apoptosis. In contrast, the same extract showed an opposite effect when tested on human peripheral blood lymphocyte (PBL) and NKL (natural killer) cell line, in which in-vitro induction of proliferation and activation of these cells was observed. The intraperitoneal injection or oral administration of LACE in nude mice inhibited in-vivo tumour growth of Ando-2 melanoma cells and prolonged the survival day of the mice. Two triterpene glycosides from the flowers, calendulose F 6'-*O*-*n*-butyl ester (9) and calendulose G 6'-*O*-*n*-methyl ester, exhibited potent cytotoxic effects against colon cancer, leukaemia and melanoma cells (Ukiya et al. 2006).

Simultaneous administration of *C. officinalis* flower extract to tumour-bearing male C57BL/6 mice reduced the lung B16F-10 melanoma tumour nodules by 74 % with 43.3 % increase in life span (Preethi et al. 2010). Elevated levels of hydroxyproline, uronic acid, hexosamine, serum sialic acid and γ -glutamyl transpeptidase in the metastatic controls were significantly lowered in the *C. officinalis*-treated animals. The extract

also inhibited expression of MMP-2, MMP-9, prolyl hydroxylase and lysyl oxidase and activated TIMP-1 and TIMP-2 and downregulated proinflammatory cytokines. The results indicated antimetastatic effects of *Calendula officinalis* flowers through the inhibition of key enzymes were involved in processes of metastasis.

Studies demonstrated that chamomile and Marigold (*Calendula officinalis*) tea exerted selective dose-dependent cytotoxic action against target cancer cells; cytotoxicity of Marigold tea was higher than chamomile (Matić et al. 2013). However, the cytotoxic effect of chamomile tea was very weak to healthy peripheral blood mononuclear cells (PBMC), while the effect of Marigold tea on PBMC was more pronounced. Marigold tea exerted highly selective antitumor effect especially to melanoma Fem-x cells in comparison to the action to normal healthy PBMC. Chemical analyses showed that dominant phenolic compounds in examined infusions and decoctions were flavonoid glycosides and hydroxycinnamic acid derivatives. Ethanol extracts of *C. officinalis* and other Asteraceae species were found to have antileukemic properties and to induce J-45.01 human acute T leukaemia cell death via apoptosis. The correlation between antileukemic activity and total polyphenol content was determined (Wegiera et al. 2012).

Three major flavonoid fractions separated from *C. officinalis* flower methanol extract did not exhibit inhibitory effect on the parent and tamoxifen-resistant T47D human breast cancer (Ostad et al. 2004). Quercetin increased cell proliferation of the resistant T47D cells in the presence of tamoxifen but no effect was detected by using quercetin itself. Also it was found that isorhamnetin did not have any proliferative or antiproliferative activity on the both cell lines.

Wound Healing Activity

Studies on surgically induced skin wound in Wistar albino rats showed that application of % unguentum containing fractions C1 and C5, isolated from *Calendula officinalis* flowers of in combination with allantoin, significantly stimulated

physiological skin regeneration and epithelialization (Klouček-Popova et al. 1982).

In-vitro studies showed that chick chorioallantoic membrane (CAM) treated with a freeze-dried aqueous extract of *C. officinalis* flowers were positive for hyaluronan, a tissue glycosaminoglycan associated with neovascularization; no hyaluronan was found in control CAMs (Patrick et al. 1996). The numbers of microvessels in calendula-treated CAMs were statistically and significantly higher than in the control CAMs. Although the extract contained water-soluble compounds such as flavonoids, the exact nature of the active angiogenic component(s) was yet to be identified.

Studies showed that rats with experimentally induced burns treated with *Calendula officinalis* flower extract showed significant improvement in healing when compared with the control untreated animals (Preethi and Kuttan 2008). The indicators of the wound healing such as collagen hydroxyproline and hexosamine contents were significantly augmented in the treated group indicating accelerated wound healing in the treated animals. The acute phase proteins haptoglobin and orosomucoid which were elevated due to burn injury were lowered significantly in 200 mg/kg body weight extract-treated animals. The antioxidant defense mechanism, which was decreased in the liver during burn injury, was enhanced in treated animals. The lipid peroxidation was significantly lowered in the treated group when compared to control animals. Tissue damage marker enzymes alkaline phosphatase, alanine and aspartate transaminases were significantly lowered in the treated groups in a dose-dependent manner. The histopathological analyses of skin tissue also confirmed the increased healing potential of the extract after burn injury. Another study reported that rats with excision wounds treated with *Calendula officinalis* flower extract had 90 % wound closure compared with 51.1 % in the control group on the eighth day of wounding (Preethi and Kuttan 2009b). The days needed for reepithelialization were 17.7 for the control animals; extract treatment at a dose of 20 or 100 mg/kg body weight reduced the period to 14 and 13 days, respectively. A significant increase

was observed in the hydroxyproline and hexosamine content in the extract-treated group compared with the untreated animals. *Calendula* extracts were found to have wound healing effect using the scratch assay (Fronza et al. 2009). The hexane and ethanol extracts of *Calendula officinalis* stimulated proliferation and migration of Swiss 3 T3 albino mouse fibroblasts at low concentrations, for example, 10 µg/ml enhanced cell numbers by 64.35 and 70.53 %, respectively. Inhibition of proliferation showed that this effect was mainly due to stimulation of migration. The triterpenoids, faradiol myristate and palmitate gave comparable stimulation rates at an almost 50 µg/ml concentration, indicating that they contributed partially but not most significantly to the wound healing effects of *Calendula* preparations.

Studies by Parente et al. (2012) found that the ethanol extract, the dichloromethane and hexanic fractions of *C. officinalis* flowers presented anti-inflammatory and antibacterial activities as well as angiogenic and fibroplastic properties acting in a positive way on the inflammatory and proliferative phases of the healing process as through the chorioallantoic membrane and cutaneous wounds in rat models. The angiogenic activity of *C. officinalis* flower ethanol extract and dichloromethane and hexanic fractions was evidenced in both experimental models using 36 rats and 90 embryonated eggs to evaluate healing and angiogenic activities through the induction of skin wounds and the chorioallantoic membrane, respectively (Parente et al. 2011). They verified that this effect was not directly related to the expression of vascular endothelial growth factor (VEGF) and it could be associated to other pro-angiogenic factors. Their data suggested the healing activity of *C. officinalis* could be related, among other factors, to its positive effect on angiogenesis, characterized by the induction of neovascularization. In a prospective nonrandomized pilot study of 25 patients (10 men and 15 women) with venous ulcers, 7 week treatment with the herbal-based ointment Herbadermal® comprising extracts of garlic, St. John's wort and calendula elicited 99.1 % epithelialization without significant effects on the microbial flora

(Kundaković et al. 2012). Based on this, they recommended the herbal-based ointment as topical treatment for wound healing because of its epithelializing, anti-erythematous and antiedematous properties.

Hepatoprotective and Nephroprotective Activities

Animal studies showed that the flower extract of *C. officinalis* had a protective effect against CCl₄-induced acute hepatotoxicity and cisplatin-induced nephrotoxicity (Preethi and Kuttan 2009a). The activities of serum marker enzymes of liver injury like glutamate pyruvate transaminase (SGPT), glutamate oxaloacetate transaminase (SGOT) and alkaline phosphatase (ALP) which were elevated by CCl₄ injection were found to be significantly reduced by the pretreatment of the flower extract at 100 and 250 mg/kg body weight. The lipid peroxidation in liver, the marker of membrane damage and the total bilirubin content in serum were also found to be at significantly low level in the extract pretreated group. The elevated kidney urea and creatinine levels in cisplatin-treated animals were significantly lower in the flower extract pretreated groups (100 and 250 mg/kg body weight). Moreover, cisplatin-induced myelosuppression was ameliorated by the flower extract pretreatment. Treatment with the extract produced enhancement of antioxidant enzymes—superoxide dismutase and catalase and glutathione.

Antidermatitic/Radioprotective/Skin Therapeutic Activities

In a phase III randomized trial of *Calendula officinalis* (126 patients) compared with trolamine (128 patients) Calendula treatment was found to reduce acute dermatitis during irradiation for breast cancer (Pommier et al. 2004). The occurrence of acute dermatitis of grade 2 or higher was significantly lower with the use of calendula (41 %) than with trolamine (63 %). Moreover, patients receiving calendula had less frequent

interruption of radiotherapy and significantly reduced radiation-induced pain. *Calendula* was considered to be more difficult to apply, but self-assessed satisfaction was greater. Body mass index and adjuvant chemotherapy before radiotherapy after lumpectomy were significant prognostic factors for acute dermatitis. Marigold (*Calendula officinalis*) and rosemary cream preparations were found to be effective against experimentally induced irritant contact dermatitis in healthy volunteers (Fuchs et al. 2005). In a prospective assessment phase III study, *Calendula officinalis* was shown to be superior to trolamine for the prevention of radio-epithelitis (Chargari et al. 2009). In another study of topical products used in the prevention of radiodermatitis, to support care delivery to women with breast cancer during teletherapy, de Andrade et al. (2012) found that *Calendula*, corticosteroids and Xclair have shown significant protective effects against radiodermatitis. Data from a randomized and double-blind study of 66 infants with diaper dermatitis suggested that topical application of aloe vera cream and *Calendula officinalis* ointment could serve as safe and effective treatment for the treatment of diaper dermatitis in infants (Panahi et al. 2012).

The hydroalcoholic extract of *C. officinalis* was found to contain polyphenol, flavonoid, rutin and narcissin contents of 28.6, 18.8, 1.6, and 12.2 mg/g, respectively (Fonseca et al. 2010). The extract exhibited in-vitro dose-dependent antioxidant activity against different radicals. Cytotoxicity experiments demonstrated that the extract was not cytotoxic for L929 and HepG2 cells at concentrations less than or equal to 15 mg/ml. However, in concentrations greater than or equal to 30 mg/ml, toxic effects were observed. Further, oral treatment of hairless mice with 150 and 300 mg/kg of the extract maintained GSH levels close to nonirradiated control mice. In addition, this extract affected the activity/secretion of matrix metalloproteinases 2 and 9 (MMP-2 and -9) stimulated by exposure to UVB irradiation. The gel formulation [Formulation 3 (F3)] found to be the most effective for the topical delivery of *Calendula officinalis* extract, which was detected as 0.21 µg/cm(2) of narcissin and as 0.07 µg/cm(2) of the rutin in the viable

epidermis of hairless mice exposed to ultraviolet (UV) B irradiation (Fonseca et al. 2011). This formulation was able to maintain glutathione reduced levels close to those of nonirradiated animals but did not affect the gelatinase-9 and myeloperoxidase activities increased by exposure to UVB irradiation. In addition, F3 reduced the histological skin changes induced by UVB irradiation that appeared as modifications of collagen fibrils.

Results of studies by Mishra et al. (2012a) suggested that calendula oil cream can be used to protect the skin from UV radiations in form of sunscreen cream and to maintain the natural pigmentation of the skin. The essential oil of *Calendula officinalis* flowers in cream formulation exhibited good activity sun protection factor (SPF) (SPF=14.84). In another paper they reported that treatment with creams containing 4 and 5 % of *Calendula officinalis* essential oil caused a significant decrease in the malonyldialdehyde level, whereas the levels of catalase, glutathione, superoxide dismutase, ascorbic acid and the total protein level were significantly increased after 1 month of daily UVB irradiation treatment when compared to untreated control groups (Mishra et al. 2012b). The results suggested that the cutaneous application of the essential oil of *Calendula* prevented UVB-induced alterations in the level of antioxidants in skin tissue.

In a multicentre, controlled, parallel-group study, menopausal women with vaginal dystrophy were randomized to vaginal gel EG (containing isoflavones, *Lactobacillus sporogenes*, *Calendula officinalis* extract and lactic acid) (103 women) or no topical treatment (NT, 83 women) for 4 weeks (Tedeschi et al. 2012). The severity of itching, burning, vulvovaginal erythema, vaginal dryness and dyspareunia were significantly reduced during EG treatment compared with the NT group.

Marigold therapy (*Tagetes* and *Calendula* species) had been used for over 30 years in the United Kingdom and had been evaluated by numerous randomized double-blind placebo-controlled studies for various skin problems on the lower extremity (Hadfield et al. 2008; Khan 2008). Various species of Marigold had been reported to be naturally antiviral, keratolytic and

antiinflammatory when applied topically to the affected area. In particular, through numerous research, controlled and case studies by M Taufiq Khan and M Tariq Khan specific extracts had been developed that were directly applied by the podiatric physician to the patient: an antiviral paste (for verruca), an antiinflammatory paste (for bursitis and tendonitis), a keratolytic paste (for hyperkeratosis) and an antifungal paste (for nails). Marigold therapy had been reported to provide a noninvasive and gentle treatment for difficult to treat plantar verruca, painful hyperkeratotic lesions and inflamed bursa secondary to hallux abducto valgus.

Calendula officinalis flowers and *C. officinalis* extracts are used as skin conditioning agents in cosmetics. Using the threshold of toxicological concern (TTC) approach, Re et al. (2009) evaluated their safe use in cosmetic and personal care products. For each of its known constituents, the concentration in the plant, the molecular weight and the estimated skin penetration potential were used to calculate a maximal daily systemic exposure which was then compared to its corresponding TTC class value. Owing to the variability of composition of plant extracts, back calculation was used to determine the maximum acceptable concentration of a given constituent in an extract of *C. officinalis*. Akhtar et al. (2011) evaluated the effects of newly formulated topical cream of *Calendula officinalis* extract on the mechanical parameters of the cheek skin in healthy human volunteers by using the cutometer, a device that is designed to measure the mechanical properties of the skin in response to the application of negative pressure. After 8 weeks, the instrumental measurements produced by formulation reflected significant improvements in hydration and firmness of skin.

Antiinflammatory Activity

Russian studies reported that preparations of calendula alleviated the signs of chronic inflammatory conjunctivitis and other chronic ocular inflammatory conditions in laboratory animals (Marinchev et al. 1971; Mozherenkov and Shubina 1976).

The triterpenoids were shown to be the most important antiinflammatory principles of *C. officinalis* flower CO₂ extract (Della Loggia et al. 1994). Among them, the faradiol monoester appeared to be the most relevant principle for the activity of the extract, due to its quantitative prevalence. The unesterified faradiol, not present in the extract, was the most active of the tested compounds and equalled indomethacin in activity, whereas the monools ψ -taraxasterol, lupeol, taraxasterol and β -amyrin were less active than the free diol. Isorhamnetin glycosides isolated from *Calendula officinalis* were found to inhibit the activity of lipoxygenase in vitro (Bezákova et al. 1996). All of the triterpene alcohols helianol, taraxasterol, ψ -taraxasterol, α -amyrin, β -amyrin, lupeol, taraxerol, cycloartenol, 24-methyl-enecycloartenol, tirucalla-7,24-dienol and dammaradienol isolated from the tubular flowers of *Calendula officinalis*, *Carthamus tinctorius*, *Cosmos bipinnatus*, *Chrysanthemum morifolium*, *Helianthus annuus* and *Matricaria matricarioides* exhibited marked antiinflammatory activity against 12-*O*-tetradecanoylphorbol-13-acetate-induced inflammation (1 μ g/ear) in mice, and their 50 % inhibitory dose was 0.1–0.8 mg/ear (Akihisa et al. 1996). Faradiol esters, namely, faradiol-3-myristic acid ester and faradiol-3-palmitic acid ester, isolated from *C. officinalis* flower heads showed nearly the same dose-dependent anti-oedematous activity in the inhibition of Croton oil-induced oedema of the mouse ear, and no significant synergism appeared with their mixture (Zitterl-Eglseer et al. 1997). The free monol, ψ -taraxasterol, had a slightly lower effect and showed the same effect as an equimolar dose of indomethacin. Furthermore, faradiol was more active than its esters and than ψ -taraxasterol. The major antiinflammatory triterpenoid esters purified from *C. officinalis* flower heads were faradiol-3-*O*-laurate, faradiol-3-*O*-myristate and faradiol-3-*O*-palmitate (Hamburguer et al. 2003). Accompanying minor compounds of the triterpene ester fraction purified included maniladiol 3-*O*-laurate, maniladiol-3-*O*-myristate, ψ -taraxasterol and β -amyrin.

Three new terpenoid derivatives derived by systematic chemical modifications of faradiol

from *C. officinalis* flowers, the C(16) benzyl ether 15, the C(30) aldehyde 24 and the C(30) primary alcohol 25 showed significantly improved antiinflammatory potencies in the inhibition of croton oil induced ear oedema in mouse (Neukirch et al. 2005). In evaluation of oleanane-type triterpene glycosides 1–9 isolated from the flowers for inhibitory activity against 12-*O*-tetradecanoylphorbol-13-acetate (TPA)-induced inflammation (1 μ g/ear) in mice, calendulaglycoside A (1), calendulaglycoside A 6'-*O*-*n*-methyl ester (2), calendulaglycoside A 6'-*O*-*n*-butyl ester (3), calendulaglycoside B (4), calendulaglycoside B 6'-*O*-*n*-butyl ester (5), calendulaglycoside C (6), calendulaglycoside C 6'-*O*-*n*-methyl ester (7), calendulaglycoside C 6'-*O*-*n*-butyl ester (8) and calendulose F 6'-*O*-*n*-butyl ester (9), all except compound (1), exhibited marked antiinflammatory activity, with ID₅₀ values of 0.05–0.20 mg/ear (Ukiya et al. 2006).

Oral administration of 250 and 500 mg/kg body weight *Calendula officinalis* flower extract produced significant inhibition (50.6 and 65.9 %, respectively) in paw oedema of animals induced by carrageenan and 41.9 and 42.4 %, respectively, with inflammation produced by dextran (Preethi et al. 2009). In chronic antiinflammatory model using formalin, administration of 250 and 500 mg/kg body weight *Calendula* extract produced an inhibition of 32.9 and 62.3 %, respectively, compared to controls. TNF-alpha production by macrophage culture treated with lipopolysaccharide (LPS) was found to be significantly inhibited by *Calendula* extract. Furthermore, elevated levels of proinflammatory cytokines IL-1beta, IL-6, TNF-alpha and IFN-gamma and acute phase protein, C-reactive protein (CRP), in mice induced by LPS injection were inhibited significantly by the extract. LPS-induced cyclooxygenase-2 (Cox-2) levels in mice spleen were also found to be inhibited by the extract. The results showed that potent antiinflammatory response of *C. officinalis* extract may be mediated by the inhibition of proinflammatory cytokines and Cox-2 and subsequent prostaglandin synthesis.

In a study of 103 children aged 6–18 years diagnosed with otalgia associated with acute otitis media (AOM), Otikon, an ear drop formulation of

naturopathic origin (containing *Allium sativum*, *Verbascum thapsus*, *Calendula flores* and *Hypericum perforatum* in olive oil), was found to be as effective as anesthetic ear drops and was proven appropriate for the management of AOM-associated ear pain (Sarrell et al. 2001). In a subsequent double-blind trial in an outpatient community clinic involving a total of 171 children aged 5–18 years with otalgia and otitis media, they found the herbal formulation Naturopathic Herbal Extract Ear Drops (NHED) (comprising *Allium sativum*, *Verbascum thapsus*, *Calendula flores*, *Hypericum perforatum*, lavender and vitamin E in olive oil) to be beneficial. Results were better in the NHED group than in the controls (Sarrell et al. 2003).

Calendula officinalis, rich in quercetin, carotenoids, lutein, lycopene, rutin, ubiquinone, xanthophylls and other antioxidants, at 2–3 %, completely inhibited human matrix metalloproteinase 2 (MMP-2) activity and human gingival fibroblast-mediated collagen degradation more than the corresponding concentration of quercetin (Saini et al. 2012). They attributed this to additional components in *Calendula* other than quercetin.

Cell Growth Stimulating Activity

The heptane, ethyl acetate and methanol extracts of *Calendula officinalis* flowers, were found to stimulate cell growth when introduced to a human skin fibroblast (HSF) cells culture and a culture of human breast cancer cells (T47D), cell culture collection ECACC number 85102201 (Matysik et al. 2005). The ethyl acetate but not the heptane and methanol extracts in concentrations above 25 µg/ml stimulated cell proliferation and cellular metabolism by increase of mitochondrial dehydrogenase activity. However, concentrations exceeding 75 µg/ml were toxic for cells.

Exfoliative Cheilitis Therapeutic Activity

Roveroni-Favaretto et al. (2009) described a case of recurrent exfoliative cheilitis in an 18-year-old

man that responded to treatment with a standardized topical preparation of *Calendula officinalis*.

Hypoglycaemic, Gastric Emptying and Gastroprotective Activities

The methanol extract and its 1-butanol-soluble fraction from *Calendula officinalis* flowers were found to show a hypoglycaemic effect, inhibitory activity of gastric emptying and gastroprotective effect (Yoshikawa et al. 2001). From the 1-butanol-soluble fraction, four new triterpene oligoglycosides, calendasaponins A, B, C and D, were isolated and were shown to exhibit potent inhibitory effects on an increase in serum glucose levels in glucose-loaded rats, gastric emptying in mice and ethanol- and indomethacin-induced gastric lesions in rats. Some structure-activity relationships are discussed. They further isolated two new ionone glucosides (officinosides A and B) and two sesquiterpene oligoglycosides (officinosides C and D), from the flowers of Egyptian *Calendula officinalis* (Marukami et al. 2001).

Hypotensive and Sedative Activity

Animal studies found that high doses of *Calendula* exhibited sedative effect and also reduced blood pressure (Bojadjev 1964). For this reason, it might not be safe to combine calendula with sedative or blood pressure medications.

Antipyretic and Analgesic Activities

Crude ethanol extract of *C. officinalis* displayed significant antipyretic (74.95 % inhibition at a dose of 300 mg/kg) and analgesic (27.42 % inhibition at a dose of 40 mg/kg) in rat models (Ahmad et al. 2000). The extract not only reversed induced hyperthermia but also affected normothermia in rats. The extract at a dose of 20 mg/kg was as potent in its analgesic properties as acetylsalicylic acid at 40 mg/kg.

Antiulcerogenic Activity

Calendulozide B, trioside of oleanolic acid, isolated from *C. officinalis* roots was shown to have antiulcerogenic activity (Iatsyno et al. 1978). In oral doses of 5, 10, 20 and 50 mg/kg, it exerted an antiulcerous action in three experimental ulcer models (caffeine-arsenic induced, butadion induced and pylorus ligation induced) and also exhibited antiphlogistic and sedative action. It was devoid of effects on the cardiovascular system, the tone of intestinal smooth muscles, the diuretic renal function, the electrolytes excretion with urine or on the biligenic function of the liver. It had no local irritation properties, manifested a relatively low haemolytic activity and an insignificant toxicity both with its one-time and chronic administration.

In a clinical trial of 24 patients with chronic nonspecific colitis, treatment of an herbal combination of *Taraxacum officinale*, *Hipericum perforatum*, *Melissa officinalis*, *Calendula officinalis* and *Foeniculum vulgare* abrogated spontaneous and palpable pains along the large intestine in 95.83 % of the patients by the 15th day of their admission to the clinic Chakurski et al. 1981). Defecation became daily in the patients with obstipation syndrome. In another clinical trial, 137 patients (78 with duodenal ulcer and 59 with gastroduodenitis) were treated only with the herbal combination of *Symphytum officinalis* and *Calendula officinalis* and 33 (21 with duodenal ulcer and 12 with gastroduodenitis) were treated with the herbal combination together with antacid (Chakürski et al. 1981) As a result from the treatment, the spontaneous pains disappeared in 90 % of the patients in the group with antacid, and in the group without antacid, the dyspeptic complaints decreased over 85 %, but in the patients treated with herbs and antacid, these complaints disappeared several days earlier. The palpitation pains, in both groups, disappeared in more than 90 % of the patients within the same time. Gastric acidity, in both groups, showed a statistically insignificant tendency to decrease prior and post treatment. The ulcer niche, in both groups, was healed in almost the same percentage of the patients.

In a clinical study of patients with venous leg ulcers, after 3 weeks of treatment with an ointment of *C. officinalis* extract, of 21 patients treated, total ulcer surface area decreased by 41.7 % and 7 patients had complete epithelialization (Duran et al. 2005). In the control group of 13 patients, treated with saline solution dressings, total ulcer surface area decreased by 14.52 % and four patients had complete epithelialization. The preliminary results suggested the positive effects of the Marigold extract ointment on venous ulcer epithelialization. Studies showed that treatment of dogs with of acetic acid-induced ulcerative colitis resolved the damages of ulcerative colitis (Mehrabani et al. 2011). Loose stools, diarrhoea, gross bleeding and loss of body weight happened after administration of acetic acid, and crypt damage, loss of epithelium, infiltration of inflammatory cells and depletion of goblet cells were observed histologically.

Strychnos nux-vomica (nux vomica) and *Calendula officinalis* are used in highly diluted form in homeopathic medicine to treat patients suffering from gastritis and gastric ulcers. Results of studies suggested both drugs prepared in ethanol solution to be potent inhibitors of *Helicobacter pylori* induced gene expression (Hofbauer et al. 2010). Addition of nux vomica and *Calendula officinalis* in a 43 % ethanol solution produced a significant reduction of *H. pylori*-induced increase in gene expression of heparin-binding epidermal growth factor (HB-EGF) in gastric epithelial cell line KATO-III (reduced to 53.12 and 75.32 % vs. control), respectively. This effect was only observed when the drugs were primarily prepared in ethanol, not in aqueous solutions.

Antigingivitis Activity

Polysorb-immobilized *Calendula* was found to be highly effective in the treatment of chronic catarrhal gingivitis (Krazhan and Garazha 2001). Two patients with a diagnosis of lichen planus presenting as desquamative gingivitis who had undergone previous treatments for this condition with no significant results were treated by a handling gel containing clobetasol, nystatin, *Calendula*

officinalis, and pectin in custom trays (Machado et al. 2010). Both patients had remission of symptoms while using the trays, and after they stopped the treatment, the symptomatic outbreaks were delayed and presented as less severe symptoms in the 2 years follow-up. The treatment is aimed primarily at reducing the length and severity of symptomatic outbreaks of desquamative gingivitis.

Antimicrobial Activity

Hydroacetic extract from fresh *C. officinalis* plant inhibited the growth of *Staphylococcus aureus* at a concentration of 1 mg/ml in vitro (Dumenil et al. 1980). *Calendula* extract tested on biofilms of infant dentifrices did not demonstrate antimicrobial effects in vitro against *Actinomyces viscosus*, *C. albicans*, *Lactobacillus casei*, *Streptococcus mitis*, *Streptococcus mutans*, *Streptococcus oralis*, *Streptococcus sanguis*, and *Streptococcus sobrinus* (Modesto et al. 2000). *Melissa officinalis* and *C. officinalis* flower extracts exhibited low inhibiting activity ($MIC \geq 2,048$ mg/l) against all the tested periodontopathic bacteria species with the exception of *Prevotella* sp. (Iauk et al. 2003). Oleanolic acid isolated from Marigold (*Calendula officinalis*) inhibited bacterial growth and survival, influenced cell morphology and enhanced the autolysis of Gram-positive bacteria, suggesting bacterial envelopes were the target of its activity (Szakiel et al. 2008). The sap of *Calendula* racemes demonstrated the most profound antimicrobial effect while that of the roots was the least effective (Radioza and Iurchak 2007). *Calendula* species inhibited all tested pathogenic microorganisms, especially *Pseudomonas syringae*, *Pseudomonas fluorescens*, *Xanthomonas campestris* and *Agrobacterium tumefaciens*. Chloroform, ethanol and water extracts of *C. officinalis* leaves exhibited in-vitro antibacterial activity against Gram-positive *Bacillus subtilis*, *Staphylococcus aureus*, and Gram-negative bacteria *Escherichia coli* and *Klebsiella pneumonia*, whereas significant activity was not observed with petroleum ether extract (Chakraborty 2008). All the extracts did not show any antifungal activity.

Calendula officinalis flower extract showed high in-vitro inhibitory activity against *Aspergillus niger*, *Rhizopus japonicus*, *Candida albicans*, *Candida tropicalis* and *Rhodotorula glutinis* (Kasiram et al. 2000). The inhibitory effects of extracts were very close and identical in magnitude and were comparable with that of standard antibiotics used. The ethanol, water and n-butanol *C. officinalis* aerial plant parts extracts were found to be effective against most of the human pathogenic microorganisms: *Escherichia coli*, *Pseudomonas aeruginosa*, *Enterococcus* sp., coagulase (+) *Staphylococcus* sp., coagulase (–) *Staphylococcus* sp., *Candida albicans* and *Candida parapsilosis* (Goyal and Mathur 2011). The methanol extract of *C. officinalis* petals exhibited better antibacterial activity against most of the clinical bacteria tested than the ethanol extract (Efstratiou et al. 2012). Both methanol and ethanol extracts showed excellent antifungal activity against tested strains of fungi, comparable to fluconazole.

In a trial of 18 patients to compare the antimicrobial effect of mouthwashes (6 patients per mouthwash) containing *Calendula officinalis*, *Camellia sinensis* and 0.12 % chlorhexidine digluconate on the adherence of microorganisms to suture materials after extraction of unerupted third molars, all three mouthwashes exhibited antimicrobial activity against the adherence of microorganisms to sutures (Faria et al. 2011). However, *C. officinalis* and *C. sinensis* were not as efficient as chlorhexidine digluconate. The hydroethanol herbal extract of *C. officinalis* was one of several herbal extracts that showed high growth inhibition of *Campylobacter jejuni*, the most common cause of enteric infections, particularly among children, resulting in severe diarrhoea (Cwikla et al. 2010).

Antiviral Activity

Tinctures of *C. officinalis* flowers inhibited replication of herpes simplex virus, influenza A2 and influenza APR 8 viruses in-vitro (Bogdanova et al. 1970). However, an aqueous extract was

inactive (May and Willhun 1978). A 5 % hot aqueous extract of *Calendula* flowers inhibited replication of tick-borne encephalitis virus after intraperitoneal administration to mice (Fokina et al. 1991).

Studies found that the organic extract from *Calendula officinalis* flowers caused a significant dose- and time-dependent reduction of human immunodeficiency virus type 1 (HIV-1) reverse transcription (RT) activity in the in-vitro MTT/tetrazolium-based assay (Kalvatchev et al. 1997). An 85 % RT inhibition was achieved after 30 minutes. In addition, in the presence of the organic extract (500 µg/ml), the uninfected human lymphocytic Molt-4 cells were completely protected for up to 24 hours from fusion and subsequent death, caused by cocultivation with persistently infected U-937/HIV-1 cells. Ten oleanane-type triterpene glycosides isolated from the flowers, calendulaglycoside A (1), calendulaglycoside A 6'-*O*-*n*-methyl ester (2), calendulaglycoside A 6'-*O*-*n*-butyl ester (3), calendulaglycoside B (4), calendulaglycoside B 6'-*O*-*n*-butyl ester (5), calendulaglycoside C (6), calendulaglycoside C 6'-*O*-*n*-methyl ester (7), calendulaglycoside C 6'-*O*-*n*-butyl ester (8), calenduloside F 6'-*O*-*n*-butyl ester (9) and calenduloside G 6'-*O*-*n*-methyl ester (10), exhibited moderate inhibitory effects against the Epstein-Barr virus early antigen (EBV-EA) activation induced by 12-*O*-tetradecanoylphorbol-13-acetate (TPA), (IC₅₀ values of 471–487 mol ratio/32 pmol TPA) (Ukiya et al. 2006).

Calendula officinalis aqueous extract was found to have an immunomodulation effect against three different live viruses in broiler chickens (Barbour et al. 2004). There was a reduction in immune response to IB (infectious bronchitis) virus at 42 days of age, to ND (Newcastle disease) virus at 29 and 42 days of age, and to IBD (infectious bursal disease) virus at 14, 29 and 42 days of age in the *Calendula*-treated birds in comparison with controls. This immune reduction in *Calendula*-treated birds was associated with insignificant reduction in the bursal weight index at 42 days of age and an improvement in mean weights at 21 and 41 days of age.

Immunomodulatory Activity

Polysaccharide fractions with molecular weights in the range of 25,000–500,000 and higher isolated from *C. officinalis* and several other plants showed significant immunostimulating activities in granulocytes and carbon clearance tests (Wagner et al. 1985). Three polysaccharides isolated from *Calendula officinalis* flowers showed immunostimulating activity in several in-vitro immunological test systems (Varljen et al. 1989). Studies found that the ethanol extract of *C. officinalis* exhibited no direct mitogenic effect on human lymphocytes or thymocytes (Amirghofran et al. 2000). They showed a complete inhibitory effect on the proliferation of lymphocytes in the presence of PHA (SI (simulation index) range 0.01–0.49). Treatment of mixed lymphocytes with 0.1–10 µg/ml of *C. officinalis* (SI range 1.34–1.80) strongly increased the cell proliferation.

Calendula officinalis extract was one of several herbal extracts that was shown to be not inferior to *Echinacea purpurea* tincture in terms of stimulation of humoral immune response, phagocytic and bactericidal activity of peritoneal macrophages in mice but exceeded effect of *E. purpurea* on phagocytic activity of peripheral blood neutrophils (Borsuk et al. 2009).

Antimutagenic Activity

All 13 saponins isolated *Calendula officinalis*, *C. arvensis* and *Hedera helix* were found to be nontoxic and non-mutagenic for doses of 400 µg in the *Salmonella*/microsomal assay (Elias et al. 1990). Chlorophyllin inhibited the mutagenic activities of benzo-[a]pyrene (BaP) (1 µg) and a mutagenic urine concentrate from a smoker (5 µl) in a dose-dependent manner.

Genotoxic/Antigenotoxic Activity

A fluid extract of *Calendula officinalis* exhibited dose-dependent genotoxic properties when assayed for mitotic segregation in the heterozygous diploid

D-30 of *Aspergillus nidulans* (Ramos et al. 1998). Mutagenicity testing with the *Salmonella*/microsome assay in strains TA 1535, TA 1537, TA 98 and TA 100 was negative in a plate incorporation protocol, with concentrations ranging from 50 to 5,000 µg/plate. The extract was also negative in the mouse bone marrow micronucleus test at 1 g/kg per os. Pérez-Carreón et al. (2002) found that in the unscheduled DNA synthesis (UDS) assay in liver cell cultures, diethylnitrosamine (DEN) at 1.25 µM elicited a maximal increase of 40 % (3) H-thymidine ((3)HdTT) incorporation, and both aqueous (AE) and aqueous-ethanol (AEE) extracts of *C. officinalis* flower completely reverted the DEN effect at around 50 ng/ml and between 0.4 and 16 ng/ml, respectively. In the absence of DEN, these two polar extracts induced UDS at concentrations of 25 µg for AE and 3.7 µg/ml for AEE to 100 µg/ml in rat liver cell cultures. Concentrations producing genotoxic damage were three orders of magnitude above concentrations that conferred total protection against the DEN effect. Thus, at the lower end, ng/ml concentrations of the two polar extracts AE and AEE conferred total protection (antigenotoxic) against the DEN effect, and at the higher end, g/ml concentrations produced genotoxic effects.

No genotoxic or mutagenic effect was observed in blood and bone marrow samples from mice after 2 weeks of treatment with ethanol (250 or 500 mg/kg) or aqueous (90 mg/kg) extracts of *C. officinalis* prior to treatment with saline or methyl methanesulfonate (Leffa et al. 2012). Additionally, both extracts showed an antigenotoxic effect by Comet assay, repairing the DNA damage caused by methyl methanesulfonate. In the micronucleus test, only aqueous extract of *C. officinalis* revealed a protective effect to genetic material. The results suggested that all the extracts of *C. officinalis* contained protective substances that decreased damage to genetic material.

Hepatoprotective Activity

In a rat hepatocarcinogenesis model, *Calendula officinalis* flower extracts exhibited both protective

and cytotoxic effects dependent on the concentration used presenting a phenomenon known as hormesis (Barajas-Farias et al. 2006). The protective effect was observed at 0.1 mg/kg concentration, increased at 0.5 mg/kg and reached its maximum at 2.5 mg/kg, when it decreased the area and number of altered foci by 55 and 49 %, respectively, in comparison with rats treated only with carcinogen, *N*-nitrosodiethylamine. Ten and 20 mg/kg doses produced a notorious increment in the area and number of altered hepatic foci, and at 40 mg/kg of extract the increment was 40 and 53 %, respectively.

Cardioprotective Activity

Animal studies showed that *C. officinalis* ameliorated myocardial ischemic reperfusion injury (Ray et al. 2010). Rat hearts perfused with *C. officinalis* prior to subjecting the heart to ischaemia and achieved cardioprotection by stimulating left ventricular developed pressure and aortic flow as well as by reducing myocardial infarct size and cardiomyocyte apoptosis. Cardioprotection appeared to be achieved by changing ischaemia reperfusion-mediated death signal into a survival signal by modulating antioxidant and antiinflammatory pathways as evidenced by the activation of Akt and Bcl2 and depression of TNF-α.

Spasmogenic and Spasmolytic Activities

The crude aqueous-ethanol extract of *Calendula officinalis* flowers was found to contain both spasmolytic and spasmogenic constituents, exhibiting these effects through calcium channel blocking and cholinergic activities (Bashir et al. 2006). In isolated rabbit jejunum, the extract caused a dose-dependent (0.03–3.0 mg/ml) relaxation of spontaneous and K⁺-induced contractions, suggestive of calcium channel blockade. In a few preparations, a mild non-reproducible spasmogenic effect was observed at lower doses, followed by relaxation. Activity-directed fractionation revealed that the spasmolytic activity of

the plant was concentrated in its organic fractions. The aqueous fraction exhibited a marked atropine sensitive spasmogenic effect but was found to be devoid of any spasmolytic effect. The study provided a scientific base for its traditional use in abdominal cramps and constipation.

Uterotonic Activity

A crude water extract of *C. officinalis* was found to enhance the uterine tonus in isolated rabbit and guinea pig uterine horn (Shipochliev 1981).

Estrogenic Activity

Two Polish studies in early 1960s reported that calendula flower extracts exhibited some estrogenic activity in ovariectomized mice (Banaszkiewicz and Mrozikiewicz 1962; Banaszkiewicz et al. 1962).

Insecticidal Activity

A study on human volunteers showed that the essential oils of myrtle and Marigold (*Calendula officinalis*) exhibited repellency against *Anopheles stephensi*, vector of malaria disease, but was generally lower than DEET, a synthetic repellent (Tavassoli et al. 2011). The protection time of 50 % essential oils of Marigold and myrtle were respectively 2.15 and 4.36 hours compared to 6.23 hours for DEET 25 %. The median effective dose (ED₅₀) of essential oils was 0.1105 and 0.6034 mg/cm², respectively, for myrtle and Marigold.

Antiparasitic Activity

Glycosides of oleanolic acid, isolated from Marigold, inhibited the development of L3 *Heligmosomoides polygyrus* larvae, the infective stage of the intestinal parasitic nematode (Szakiel et al. 2008). Furthermore, both oleanolic acid and its glycosides reduced the rate of L3 survival dur-

ing prolonged storage, but only oleanolic acid glucuronides affected nematode infectivity.

Molluscicidal Activity

Studies found that the *Calendula micrantha officinalis* flower ethanol extract higher molluscicidal activity against *Lymnaea cailliaudi*, Fascioliasis-transmitting snail, than the leaf extract with LC₅₀ of 35 and 52.17 ppm, respectively (Abd-El-Megeed 1999). The mortality rate of exposed snails was increased by prolongation of the exposure time. The molluscicidal effect resulted in enhancing energy utilization and nutrient consumption since glucose, lipids, proteins and triglycerides were greatly reduced. The stomach and digestive gland of the treated *L. cailliaudi* snails were greatly altered. Natural rubber used as a binding matrix for *Calendula officinalis* was found to be a source of molluscicidal saponin (Helaly et al. 1999). The amount of saponin released was affected by the environmental temperature and the type of fillers present in the formulations.

Allergy Problem

Members of the Compositae including *C. officinalis* had been suspected of sensitization or elicitation of Compositae dermatitis (Paulsen 2002). Sesquiterpene lactones were the most important allergens, but there were a few cases of sensitization from a coumarin, a sesquiterpene alcohol and a thiophene.

Toxicity Studies

Animal studies by Lagarto et al. (2011) found that the acute and subchronic toxicities of *C. officinalis* extracts were low. In the subchronic study with doses of 50, 250 and 1,000 mg/kg/day administered in drinking water, several of the blood elements were significantly affected in male and female Wistar rats after 90 days, haemoglobin, erythrocytes, leukocytes and blood

clotting time. For blood chemistry parameters, ALT, AST and alkaline phosphatase were affected. Histopathological examination of tissues showed slight abnormalities in hepatic parenchyma that were consistent with biochemical variations observed. In the acute study (dose of 2,000 mg/kg) there were no mortality and signs of toxicity.

Jeschke et al. (2009) conducted a prospective observational study of prescribing patterns of remedies containing Asteraceae extracts and adverse drug reactions (ADR) in Germany from these remedial extracts. Their study involved herbal medicines, containing extracts of Asteraceae such as *Echinacea* spp., *Arnica montana*, *Matricaria recutita* and *Calendula officinalis* and involved 38 physicians, 55 % of whom were general practitioners and 45 % were specialists. During the study period, a total of 50,115 patients were evaluated and 344 ADRs for conventional and complementary remedies were reported. The most frequently prescribed Asteraceae was *Matricaria recutita* (23 %), followed by *Calendula officinalis* (20 %) and *Arnica montana* (20 %). No serious ADRs for Asteraceae-containing remedies were reported. The majority of reported ADRs for Asteraceae-containing remedies were classified as uncommon. The proportional reporting ratios (PRRs) for Asteraceae-containing remedies with respect to all other prescriptions was 1.7 for the system organ class 'skin and subcutaneous tissue disorders' (six ADRs) and 1.0 for 'gastrointestinal disorders' (three ADRs). Neither result was significant. Their results indicated treatment with Asteraceae-containing remedies was not associated with a high risk of adverse drug reactions (ADRs).

In the acute toxicity test, the hydroalcohol extract of *Calendula officinalis* failed to cause death in the animals after administration of oral doses up to 5.0 g/kg (Silva et al. 2007). Oral treatment with the extract at 0.025, 0.25, 0.5 and 1.0 g/kg did not induce hematological alterations when compared with the control group. In the biochemical parameters, there was an increase in blood urea nitrogen and in alanine transaminase levels. Morphological examination of the brain,

kidney and heart did not show any alteration. However, inflammatory sites were found in the lung and liver, which were associated, respectively, with oral gavage and a possible hepatotoxic effect. The extract was nontoxic in rats, although there was evidence of renal and liver overload. Subsequent studies by Silva et al. (2009) showed that the treatment of Wistar rats with hydroalcohol extract of *Calendula officinalis* flowers did not affect male reproductive parameters. Besides, it was nontoxic in the pre-implantation and organogenic periods (early and middle periods) of pregnancy. However, the extract induced a decrease in the maternal weight gain when administered during the foetal period.

The Cosmetic Ingredient Review (CIR) Expert Panel in their final report concluded that *Calendula officinalis*-derived cosmetic ingredients were safe for use in cosmetics in the practices of use and concentration given in the amended safety assessment (Andersen et al. 2010). *C. officinalis* extract, *C. officinalis* flower, *C. officinalis* flower extract, *C. officinalis* flower oil, and *C. officinalis* seed oil are cosmetic ingredients derived from *C. officinalis*. These ingredients may contain minerals, carbohydrates, lipids, phenolic acids, flavonoids, tannins, coumarins, sterols and steroids, monoterpenes, sesquiterpenes, triterpenes, tocopherols, quinones, amino acids and resins. These ingredients were not significantly toxic in single-dose oral studies using animals. The absence of reproductive/developmental toxicity was inferred from repeat-dose studies of coriander oil, with a similar composition. Overall, these ingredients were not genotoxic. They also were not irritating, sensitizing or photosensitizing in animal or clinical tests but may be mild ocular irritants.

Traditional Medicinal Uses

Calendula officinalis is used medicinally in Europe, China and India among several other places in the world (Muley et al. 2009) and is one of the most common and versatile herbs in western herbal medicine and popularly used as domestic medicine (Grieve 1971; Chevallier

1996). The whole plant, in particular the flowers and the leaves, are deemed antiphlogistic, antiseptic, antispasmodic, aperient, astringent, cholagogue, diaphoretic, emmenagogue, stimulant and vulnerary (Uphof 1968; Grieve 1971; Chiej 1984; Chevallier 1996). *Calendula officinalis* has been widely used from time immemorial in Indian and Arabic cultures as an antiinflammatory agent to treat minor skin wound and infections, burns, bee stings, bites, sunburn, sprains, wounds, sore eyes, ulcers, varicose veins and cancer (Grieve 1971; Chiej 1984; Ray et al. 2010). Pot Marigold is taken internally in treating fevers and chronic infections (Grieve 1971; Chevallier 1996) and used internally in order to speed the healing of wounds (Castro 1996) and prevent suppuration (Grieve 1971). The leaves, blossoms and buds are used to make a homeopathic remedy (Castro 1996). Leaves eaten as salad were considered useful in the treatment of scrofula in children. The petals are used in herbal tea taken to ease varicose veins. The crushed stems are applied to warts and corns. Pot Marigold is also used as a bactericide, antiseptic and antiinflammatory.

Other Uses

Potted Marigolds are grown all over the world for ornamental purposes and also as medicinal herbs in many cultures. Calendula flowers can be used as cut flowers. In eastern countries, Marigold flowers are used in garlands for social and religious purposes. The flowers also provide a yellow dye used for fabrics, cosmetics and food. Potted Marigold plant extracts are widely used in cosmetics presumably due to presence of compounds such as saponins, flavonoids, resins and essential oils. Potted Marigold is also an important dietary and medicinal source of carotenoids such as lutein, lutein esters, zeaxanthin, auroxanthin and flavoxanthin.

Calendula officinalis can be grown as an intercrop or use as soil amendments to deter insect and soil pests. Studies found that intercropping with pot Marigold (*C. officinalis*) afforded the most effective pest control on white cabbage (Jankowska et al. 2009). Populations

and ovipositing activities of cabbage pests, namely, cabbage aphid *Brevicoryne brassicae*, flea beetles *Phyllotreta*, small white butterfly *Pieris rapae*, large white butterfly *Pieris brassicae*, cabbage moth *Mamestra brassicae* and larvae and pupae of the diamondback moth *Plutella xylostella*, were significantly reduced. Studies found that when used as a soil mulch (compost), the plant can significantly reduce root-knot nematode, *Meloidogyne incognita*, population in quito orange (*Solanum quitoense*) plantings (Betancourth García et al. 2011). Pérez et al. (2003) found that amending soil with *C. officinalis* flowers significantly reduce reproduction rate of *Meloidogyne artiellia* on chickpea compared to the non-amended treatment.

Comments

C. officinalis is widely grown in Europe, now mainly as an ornamental. It is widely cultivated in the CIS (Commonwealth of Independent States comprising Belarus, Russian Federation and Ukraine) republics, Holland, and in Germany as an herbal medicine.

Swedish: Blågubbar, Blåklint, Blåklätt, Klint

Turkish: Maviçiçek, Peygamber Çiçeği

Welsh: Glas Yr Yd, Penlas Yr Yd

Origin/Distribution

Cornflower is indigenous to Europe, where it occurs as a weed in fields.

Agroecology

It is found especially on porous, nutrient-rich soils with pH 6.6–7.6 in grain fields, rye fields, fallow land, wasteland and roadsides in its native range. It thrives in full sun but has high average daily water requirement.

Edible Plant Parts and Uses

The flowers are eaten cooked or raw as vegetables in salads or as garnish (Facciola 1990; Bown 1995; Rop et al. 2012). An edible blue dye is obtained from the flowers, used for coloring sugar and confections. The young shoots are also eaten (Chiej 1984).

Botany

A robust, herbaceous annual, 20–85 cm with grey-green, distally branched, weakly tomentose, slender stem. Leaves gray-tomentose, alternate, basal leaves linear-lanceolate, 3–10 cm, with entire margins sparsely toothed and acute apices, petiolated, cauline leaves linear, sessile with entire margins. Flower heads (capitula) rounded or flat-topped cymbiform arrays, 2.5–3.5 cm diameter, on long peduncles surrounded by campanulate involuclral bracts. Phyllaries green, ovate to oblong, tomentose to subglabrous, margins and erect appendages white to dark brown or black fringed

Plate 1 Opened and unopened cornflowers

with slender teeth (Plate 1). Capitula's ray florets 25–35, violet blue–blue (Plate 1) (sometimes pinkish or white), obliquely funnel-shaped, tip lobed, those of sterile florets raylike and enlarged, 20–25 mm those of fertile florets 10–15 mm; disc florets violet blue, tubular, in the centre of capitula. Stamens 5. Pistil of 2 fused carpels. Fruit elliptic, flattish, yellowish, fine-haired, 3.5–4 mm (0.14–0.16 in.) long cypsela, tip with short, stiff unequal bristles.

Nutritive/Medicinal Properties

Rop et al. (2012) reported that edible flowers of *Centaurea cyanus* had a dry matter content (%w/w) of 9.75 %, crude protein of 6.73 g/kg and the following elements (mg/kg fresh mass (FM)): P 534.48 mg, K 3568.77 mg, Ca 246.18 mg, Mg 138.49 mg, Na 74.28 mg, Fe 6.89 mg, Mn 2.29 mg, Cu 0.89 mg, Zn 7.59 mg and Mo 0.49 mg.

From the aerial plant parts, six flavonoid aglycons (quercetin, kaempferol, isorhamnetin, apigenin, luteolin, hispidulin), 8 flavonoid glucosides (quercetin 7-*O*-β-D-glucoside (quercimeritrin), isorhamnetin-7-*O*-β-D-glucoside, kaempferol 7-*O*-β-D-glucoside, apigenin 4'-*O*-β-D-glucoside, apigenin 7-*O*-β-D-glucoside (cosmosiin), luteolin 7-*O*-β-D-glucoside (cynaroside), apigenin 7-apioglucoside (apiin), luteolin 7-apioglucoside (graveobioside)) and four hydroxycinnamic acids (caffeic, chlorogenic, neochlorogenic and

isochlorogenic acids) were isolated (Litvinenko and Bubenchikova 1988). Also, amino acids arginine, serine, methionine, proline, glutamic acid, tryptophan, alanine, phenylalanine and threonine were detected. Apigenin-4'-*O*-(6-*O*-malonylglucoside)-7-*O*-glucuronide, methyl-apigenin and methyl-vitexin, cyanidin-3-*O*-succinylglucoside-5-*O*-glucoside/centaurocyanin (the marker compound), cyanidin-3,5-diglucoside/cyanidin, quercetin-3-*O*-gluco-rhamnoside/rutoside, isorhamnetin-7-*O*-glucoside, naringenin and naringenin-7-*O*-gluco-rhamnoside were also reported from cornflower (Pirvu et al. 2012).

The following phenolic compounds were found in the flowers: *cis* and *trans*-caffeic acids, protocatechuic and chlorogenic acids, *p*-hydroxybenzoic, *p*-coumaric, vanillic, syringic, ferulic, salicylic and benzoic acids, as well as *cis*-sinapic acid, *trans*-sinapic acids or *o*-hydroxyphenylacetic acid and *p*-hydroxyphenylacetic acids (Murav'eva and Bubenchikova 2007; Pirvu et al. 2012) and coumarins: 7-hydroxy-6-methoxycoumarin (scopoletin) and 7-hydroxycoumarin umbelliferone (Bubenchikova 1990).

Blue cornflower pigment protocyanin was found to have a complex of six molecules each of anthocyanin (centaurocyanin, cyanidin 3-*O*-(6-*O*-succinylglucoside)-5-*O*-glucoside) and flavones glycoside (apigenin 7-*O*-glucuronide-4'-*O*-(6-*O*-malonylglucoside), with metals one ferric iron, one magnesium and two calcium ions (Shiono et al. 2005; Takeda et al. 2005). *Centaurea cyanus* flowers were found to contain phenylpropanoid compounds, flavonoids and anthocyanins and tannins (Chiru 2009). Anthocyanins were found to confer diuretic, antiinflammatory and healing properties. Red flowers were found to have four to five times more anthocyanins and also phenolic compounds than blue flowers.

The methanol extract of the seeds of *Centaurea cyanus* afforded four indole alkaloids: moschamine, *cis*-moschamine, centcyamine and *cis*-centcyamine (Sarker et al. 2001). Epoxylignans, berchemol and larciresinol 4-*O*- β -D-glucopyranoside were found in the seeds of *C. cyanus* (Shoeb et al. 2004).

Volatiles emitted from mechanically damaged *C. cyanus* leaves included predominantly (100–1,000 μ g) *cis*-3-hexenyl acetate; *cis*-3-hexenol,

β -caryophyllene and germacrene D; *trans*- β -farnesene (38–100 μ g) and 1–37 μ g of *trans*-2-hexenal, hexyl acetate, hexanol, *trans*-2-hexenol, α -copaene, β -cubebene, γ -amorphene/ γ -muurolene, α -muurolene, unknown sesquiterpene, bicyclogermacrene, δ -cadinene and geranylacetone (Beck et al. 2008). *C. cyanus* had been reported to attract the weevil, *Ceratapion basicorne*, a candidate for biological control.

Antioxidant Activity

Cornflowers were found to have a total antioxidant capacity of 6.81 g ascorbic acid equivalent/kg fresh mass (FM), a total phenolic content of 4.76 g gallic acid/kg/FM and total flavonoid content of 1.81 g rutin/kg FM (Rop et al. 2012).

Antiinflammatory Activity

Different pharmacological experiments (inhibition of carrageenan, zymosan and croton oil-induced oedemas, inhibition of plasma haemolytic activity, induction of anaphylatoxin activity) showed that polysaccharides extracted from *C. cyanus* flower heads had antiinflammatory properties and interfered with complement (Garbacki et al. 1999). Additionally, these polysaccharides were found to be mainly composed of galacturonic acid, arabinose, glucose, rhamnose and galactose. The findings rationalized the use of cornflower flowers in European phytotherapy for the treatment of minor ocular inflammations.

Cytotoxicity Activity

Four indole alkaloids, moschamine, *cis*-moschamine, centcyamine and *cis*-centcyamine, isolated from the seeds exhibited cytotoxicity as determined by brine shrimp lethality bioassay (Sarker et al. 2001). Crude extracts of *Centaurea cyanus* exhibited cytotoxicity in *Artemia salina* and human fibrosarcoma cells, and were found to contain guaianolides (Bruno et al. 2005). The inflorescence and root ethanol extracts of *C. cyanus*

elicited antileukemic properties and induced cell death via apoptosis (Wegiera et al. 2012).

Serotoninerbic and COX Inhibitory Activities

Moschamine, a safflomid-type phenylpropenoic acid amide found in *C. cyanus*, was found to exhibit serotoninerbic and COX inhibitory activities (Park 2012). At the concentration of 10 $\mu\text{mol/l}$, moschamine was able to inhibit forskolin-stimulated cAMP formation by 25 %, via inhibiting serotonin receptors in the OK cells. The inhibition was repressed by two 5-HT1 antagonists (Nan-190 and spiperone), suggesting that moschamine may suppress cAMP formation via binding to 5-HT1 receptors in the cells. Also, moschamine being a very potent compound inhibited COX-I by 58 % and COX-II by 54 %, at the concentration of 0.1 $\mu\text{mol/l}$.

Antiulcerogenic Activity

The crude aqueous, ethanol and acetone extracts of *C. cyanus* flower head and aerial parts were found to have potent gastroprotective effect using the stress-induced ulcer model in rats (Pirvu et al. 2012). The polyphenol fraction of the acetone extract contained high levels of polysaccharides and minerals (over 60 %) and modest level of quercetin, apigenin and caffeic acid derivatives (<1 %).

Traditional Medicinal Uses

Cornflower has been used in herbal medicine for a long time (Grieve 1971; Launert 1981; Chiej 1984; Chopra et al. 1986; Bown 1995; Chevallier 1996) but is seldom used nowadays (Chiru 2009). The dried flowers are antipruritic, antitussive, astringent, mildly diuretic, emmenagogue, ophthalmic, very weakly purgative and tonic. An infusion can be used in the treatment of dropsy, constipation, kidney ailments, or as a mouthwash for ulcers and bleeding gums. The infusion is also taken as a bitter tonic and stimulant for the liver, improving

digestion as well as improving resistance to infections. An eye wash prepared with cornflower blossoms is employed as an antiinflammatory for eye ailments, conjunctivitis, as well as to relieve strained, tired, or puffy eyes. Blue blossoms infused in water are held to have both curative and calming action for nervous disorders. Eye wash is reputed to strengthen weak eyes. Traditionally it is said to work best on blue eyes while *Plantago major* (great plantain) was used for brown eyes. The seeds are employed as a mild laxative for children. Cornflower leaves are used to create a cleansing facial steam for dry sensitive skin. A decoction of the leaves is antirheumatic.

Other Uses

The cornflower is considered to be a good companion, in small quantities, for cereal crops and a good plant for bees, butterflies and moths. Flowers are popularly used in fresh and dried floral arrangements. A blue dye is obtained from the petals when mixed with alum; the dull impart a lovely color to linen but the dye is not permanent. Extracts of the plant are used in hair shampoos and rinses.

In folklore, cornflowers were worn by young men in love; if the flower faded too quickly, it was taken as a sign that the man's love was not returned.

Comments

The blue cornflower is the national flower of Estonia and also one of the national flowers of Germany.

Thai: Khek-Huai
Vietnamese: Bạch Cúc, Cúc Hoa Trắng, Đại Cúc

Origin/Distribution

Garden Chrysanthemum is native to China. It has been introduced as an ornamental to Europe, North and South America, Asia, Australia and South Africa.

Agroecology

Chrysanthemum prefers mild cool climates and is grown in areas with mean temperature of 16–24 °C. They are frost sensitive, and low temperature below 10 °C is detrimental for plant growth, development and flowering. Optimum temperature for flowering has been reported to be in the range of 18–21 °C (De Jong 1978; Karlsson et al. 1989). Langton and Horridge (2006) found that chrysanthemum flowered earlier when grown in a 24 °C day/14 °C night temperature regime compared with alternating between continuous 114 and 24 °C conditions on 2-day or 14-day cycles. Karlsson et al. (1989) suggested that chrysanthemum flowering was dependent upon an interaction between day and night temperature, as well as the incident daily photosynthetic photon flux. They also found that a night temperature between 17 and 18 °C yielded the largest flowers and the shortest time to flower in ‘Bright Golden Anne’, regardless of day temperature or irradiance level.

van der Ploeg et al. (2007) divided chrysanthemum cultivation into a long-day (LD) period, during which the plants grow vegetatively, and a short-day (SD) period. During this latter period, flower initiation and further development takes place. The number of days from the start of SD to harvest is referred to as the reaction time, and this trait is very sensitive to temperature, showing a definite temperature optimum (De Jong 1978). Chrysanthemums are short-day (SD) plants; the natural photoperiod of about 12 hours is suitable for good flowering of most cultivars (Kofranek 1980; Kahar 2008). Kahar (2008) found that shortening the day length from about 12 hours under natural photoperiod to 8 hours with and without incandescent lighting did not really improve flowering time and flower quality of *C. morifolium* cv. Reagan Sunny.

Garden chrysanthemum thrives best in fertile, moist, well-drained slightly acidic soil rich in organic matter in full sun but will grow in less ideal conditions.

Edible Plant Parts and Uses

The flowers and young leaves are edible (Read 1946; Uphof 1968; Tanaka 1976; Facciola 1990). Leaves are cooked or boiled and used as greens or as fritters. They are tangy, bitter and mildly peppery in flavour. The leaves can also be used to flavour vinegar. An aromatic tea is also made from the leaves. The flowering heads and petals are parboiled, seasoned with vinegar or soya sauce, and served as a salad with tofu. They can also be prepared as tempura, pickled, dried or added to soups. In Chinese cuisine, chrysanthemum petals are mixed into a thick snake meat soup to enhance the flavour. In Japan, small chrysanthemum flowers are used as garnish in sashimi. A tangy aromatic tea is made from the flowers or flower petals, commonly called chrysanthemum tea, and is drunk without or with little sugar or honey. In Korea, a rice wine flavoured with chrysanthemum flowers is called ‘gukhwaju’. Chrysanthemum flowers are also widely used as a food supplement and are considered a health food by many consumers (Chu et al. 2004; Lai et al. 2007).

Botany

An herbaceous perennial grows to 1 m high with erect or ascending sometimes procumbent, sparsely branched stem with dense pubescent foliage. Leaves olive-green, aromatic, weakly pubescent to subglabrous on both surfaces on 1–2 cm long petioles. Lamina ovate to oblong ovate in outline, 4–10 cm by 3–5 cm wide, deeply cut (pinnatifid) to shallowly pinnatipartite into short, obtuse, terminal and lateral lobes (Plates 1 and 2), truncate to subcordate at the base, upper leaves entire and smaller. Capitula 3–6 cm across, numerous on 5 cm long pubescent peduncles in lax corymbs. Involucre 10–22 mm in diameter, 4–5 seriate, phyllaries outer ones deltoid-ovate,

Plate 1 Garden chrysanthemum leaves and immature flower buds

Plate 3 Close view of chrysanthemum (anemone flower type)

Plate 2 Garden chrysanthemum plants in full bloom

middle ones ovate, innermost elliptic, broader at apex. Ray florets yellow to variously coloured (pink, white, orange, lavender, purple, red, rust, bronze, olive-green) in cultivars with entire or triserrate oblong ligules (Plates 2, 3, 4, 5, 6, 7 and 8). Disc florets yellow to pale greenish-yellow with 5-toothed corolla tube. Cypselas obovoid, 1.5–2 mm, light brown.

Nutritive/Medicinal Properties

Flower Phytochemicals

Four kinds of normal saturated hydrocarbons, C_nH_{2n+2} ($n = 19–22$), namely, nonadecane, eicosane, heneicosane and docosane; and campesterol, stigmasterol, β -sitosterol, α -amyrin, palmitic

acid, linoleic acid, stearic acid, behenic acid and lignoceric acid were detected in *Chrysanthemum morifolium* petals (Takahashi et al. 1975). Also 11 free amino acids, arginine, aspartic acid, threonine, serine, glycine, proline, glutamic acid, alanine, leucine, isoleucine and valine, were identified. Two hydroxy taraxastane-type triterpenes, faradiol and heliantriol C, were isolated from the ligulate flowers of *C. morifolium* (Yasukawa et al. 1998). Content of chlorogenic acid found in the flowers were 0.060–0.467 % (Li et al. 1999). Three flavonoids in *C. morifolium* were identified as acacetin-7-*O*- β -D-glucoside, apigenin-7-*O*- β -D-glucoside and luteolin-7-*O*- β -D-glucoside (Liu et al. 2001). From *C. morifolium*, eight compounds were isolated and identified as chrysoeriol (1), apigenin (2), luteolin (3), quercetin (4), chrysoeriol-7-*O*- β -D-glucoside (5), apigenin-7-*O*- β -D-glucoside (6), luteolin-7-*O*- β -D-glucoside (7) and tilianin-7-*O*- β -D-glucoside (8) (Jia et al. 2003).

From the nonsaponifiable lipid fraction from the methanol flower extract, 24 triterpene diols and triols were isolated, of which three were new compounds: (24*S*)-25-methoxycycloartane-3 β ,24-diol, (24*S*)-25-methoxycycloartane-3 β ,24,28-triol, and 22 α -methoxyfaradiol (Ukiya et al. 2001). Faradiol (9) and heliantriol C (19), present in the nonsaponifiable lipid fraction and as the 3-*O*-palmitoyl esters in the *n*-hexane soluble fraction, were the most predominant triterpene diol and triol constituents. Fifteen pentacyclic triterpene diols and triols, consisting of six taraxastanes,

Plate 4 (a, b) *Chrysanthemum* (spider flower type)

Plate 5 *Chrysanthemum* (decorative flower type)

Plate 6 *Chrysanthemum* (single daisy-like flower type)

faradiol, heliantriol B0, heliantriol C, 22 α -methoxyfaradiol, arnidiol and faradiol α -epoxide; five oleananes, maniladiol, erythrodiol, longispinogenin, coflodiol and heliantriol A1; two ursanes, brein and uvaol; and two lupanes, calendadiol and heliantriol B2, were isolated from the nonsaponifiable lipid fraction of the edible flower extract of *C. morifolium* (Ukiya et al. 2002). The

Plate 7 *Chrysanthemum* (cushion or azalea mums flower type)

flavonoids acacetin, apigenin, luteolin and quercetin were isolated from the ethyl acetate fraction of the flower methanol extract (Miyazawa and Hisama 2003). The amount of luteolin was found to be lower than that of luteolin- β -D-glucoside (Hu et al. 2004). Two dicaffeoylquinic acids,

Plate 8 Green-flowered chrysanthemum (anemone flower type)

3,5-dicaffeoyl-epi-quinic acid and 1,3-dicaffeoyl-epi-quinic acid, were isolated from *Chrysanthemum morifolium* together with six known dicaffeoylquinic acid derivatives and three flavonoids (Kim and Lee 2005). Two flavonoid glycosides were isolated from the flowering heads and their structures elucidated as luteolin 4'-methoxy-7-*O*-(6''-*O*-acetyl)- β -D-glucopyranoside and acacetin 7-*O*-(3''-*O*-acetyl)- β -D-glucopyranoside (Zhang et al. 2006). The flowers were found to contain D-mannitol and saccharide (Cheng et al. 2008).

Sixteen xanthophylls were isolated from chrysanthemum petals among which. Among them, (3*S*,5*S*,6*R*,3'*R*,6'*R*)-5,6-dihydro-5,6-dihydroxylutein (1) and five di-*Z* geometrical isomers of lutein-5,6-epoxide, i.e., 9*Z*,13'*Z* (2), 13*Z*,9'*Z* (3), 9'*Z*,13'*Z* (4), 9*Z*,13*Z* (5), and 9*Z*,9'*Z* (7), had never before been identified as natural products (Kishimoto et al. 2004). All of the carotenoids isolated from chrysanthemum, except for (9*Z*)-violaxanthin, are β , ϵ -carotene (α -carotene) derivatives.

Total anthocyanins and total carotenoids in $\mu\text{g/g}$ fresh weight in *C. morifolium* cv. Dark Dramatic (orange flowers) were 792.7 and 343.4 μg , respectively; cv. Florida Marble (yellow flowers) was 144.9 μg and cv. Vodka Lime (yellow flowers) was 121.9 μg (Kishimoto et al. 2007). Eleven compounds were identified in the flowers; luteolin (1), quercetin (2), acacetin 7-*O*- β -D-(3''-acetyl)-glucopyranoside (3), luteolin 7-*O*- β -D-(6''-acetyl)-glucopyranoside (4), hesperetin 7-*O*- β -D-glucopyranoside (5), acacetin

7-*O*- β -D-glucopyranoside (6), diosmetin 7-*O*- β -D-glucopyranoside (7), apigenin 7-*O*- β -D-glucopyranoside (8), hesperidin (9), linarin (10) and luteolin 7-*O*- β -D-glucopyranoside (11) (Wang et al. 2008c). The common chemical constituents in the essential oil of the five Hangjuhua cultivars were juniper camphor (10.51–13.28 %), methyl β , β -dimethylbenzenepropanoic acid ester (1.51–4.89 %), 1,3,3-trimethylcyclohex-1-ene-4-carboxaldehyde, borneol, α -curcumene, α -bisabolol, *cis*-caryophyllene, benzyl benzoate, 2,4-decadienal and heneicosane (Guo et al. 2008). Juniper camphor was found to be a characteristic constituent in the essential oil of Hangjuhua. A *p*-hydroxyphenylacetyl flavonoid, diosmetin 7-(6''-*O*-*p*-hydroxyphenylacetyl)-*O*- β -D-glucopyranoside, was isolated from the flowers together with five known flavonoids, luteolin, diosmetin, diosmetin 7-*O*- β -D-glucopyranoside, diosmin and scolimoside, and four known caffeoylquinic acid derivatives, macranthoin F 3,5-dicaffeoylquinic acid, 1,3-dicaffeoyl-epi-quinic acid and chlorogenic acid (Xie et al. 2009).

Thirty-three volatiles were extracted and identified in dry chrysanthemum flowers comprising mainly unsaturated organic compounds, such as monoterpenes, sesquiterpenes and their oxygenous derivatives; triterpenoids; and aliphatic compounds (Wang et al. 2008a). The compounds included the following: camphene (112.7 $\mu\text{g/g}$), pinene (106.3 $\mu\text{g/g}$), bornyl acetate (67.3 $\mu\text{g/g}$), 3-carene (62. $\mu\text{g/g}$), eucalyptol (52.1 $\mu\text{g/g}$), 1,7,7-trimethyl-bicyclo[2.2.1]hept-2-ene (41.3 $\mu\text{g/g}$), camphor (29.4 $\mu\text{g/g}$), caryophyllene oxide (20.0 $\mu\text{g/g}$), 4-methylene-1-(1-methylethyl)-cyclohexene (13.5 $\mu\text{g/g}$), 2,2,3-trimethyl-3-cyclopentene-1-acetaldehyde (10.9 $\mu\text{g/g}$), 1-methyl-4-[1-methylethyl]-1,4-cyclohexadiene (9.2 $\mu\text{g/g}$), borneol (4.2 $\mu\text{g/g}$), 6,6-dimethyl-2-methylene-bicyclo[2.2.1]heptan-3-one (4.2 $\mu\text{g/g}$), (1*S*)-6,6-dimethyl-2-methylenebicyclo[3.1.1]heptane (3.4 $\mu\text{g/g}$), bicyc[3.1.1]hept-2-en-4-ol, 2,6,6-trimethyl-, acetate (3.1 $\mu\text{g/g}$), 6,6-dimethyl-2-methylenecyclo[3.1.1]heptane (2.7 $\mu\text{g/g}$), 4-methyl-1-[1-methylethyl]-3-cyclohexen-1-ol (1.8 $\mu\text{g/g}$), 2-methyl-5-(1-methylethyl)-bicyclo[3.1.0]hex-2-ene (1.7 $\mu\text{g/g}$), oct-1-enyl acetate (1.7 $\mu\text{g/g}$), 1-methyl-4-[1-

methylethylidene]-cyclohexene (1.6 µg/g), 2-methyl-butanoic acid 2-methylbutylester (1.6 µg/g), 4-camphene (1.4 µg/g), 3,7,7-trimethyl-bicyclo[4.1.0]hept-2-ene (1.4 µg/g), 6,6-dimethyl-bicyclo[3.1.1]hept-2-ene-2-carboxaldehyde (1.4 µg/g), isobornyl acetate (1.4 µg/g), 3-cyclopentene-1-acetaldehyde, 2,2,3-trimethyl (1.3 µg/g), 1-methyl-3-(1-methylethenyl)-cyclohexene (1.3 µg/g), 1,6,10-dodecatriene, 7,11-dimethyl-3-methylene-, [Z] (1.1 µg/g), 1 α ,2,3,5,6,7,7 α ,7 β -octahydro-1,1,7,7 α -tetramethyl-1H-cyclopropa[α]naphthalene (0.8 µg/g), 1,2,3,4,4 α ,5,6,8 α -octahydro-7-methyl-4-methylene-1-(1-methylethyl)-naphthalene (0.7 µg/g), caryophyllene (0.7 µg/g), decahydro-1,1,7-trimethyl-4-methylene-1H-cycloprop[*e*]azulen-7-ol (0.6 µg/g) and 2,3,6,7,8,8 α -hexahydro-1,4,9,9-tetramethyl-1H-3 α ,7-methanoazulene (0.6 µg/g).

Twenty-eight 3-hydroxy triterpenoids of taraxastane-type, ψ -taraxasterol, faradiol, heliantriol C, 22 α -methoxyfaradiol, faradiol α -epoxide, arnidol and taraxasterol; of oleanane type, β -amyrin, maniladiol, erythrodiol, longispinogenin and cofilol; of ursane-type α -amyrin, brein and uvaol; of lupine-type, lupeol, 3-epilupeol, calenduladiol and heliantriol B₂; of taraxane-type, taraxerol; of cycloartane-type, cycloartenol, 24-methylenecycloartanol, (24*R*)-cycloartane-3 β ,24,25-triol, (24*S*)-cycloartane-3 β ,24,25-triol and (24*S*)-25-ethoxycycloartane-3 β ,24-diol; of tirucallane-type, helianol, 4,5 α -epoxyhelianol and Δ^7 -tirucallol; and of dammarane-type, dammaradienol, were isolated from the nonsaponifiable lipid fraction of *C. morifolium* flower extract (Akihisa et al. 2005). One lupane-type 3 α -hydroxy triterpenoid (3-epilupeol) was derived from lupeol. Chlorogenic acid; 1,5-dicaffeoylquinic acid; isochlorogenic acid A; isochlorogenic acid C; luteolin-7-*O*- β -D-glucoside; and apigenin-7-*O*- β -D-glucoside were detected in *C. morifolium* flower head (Qin and Wen 2011). The contents of the components in the steam-blached flower heads were significantly higher than those non-blached. The contents of chlorogenic acid and isochlorogenic acid A in the steam-blached semi-opened flower heads were higher than fully opened ones by 53 and 41 %, respectively.

Chrysanthemum morifolium flowers afforded mixtures of the C-3 palmitate and myristate esters (3:2) of mailadiol (1), the C-3 palmitate and myristate esters (3:2) of heliantriol C (2) and fatty acid esters (1:1) of faradiol (3) and arnidol (Ragasa et al. 2005). Two acidic polysaccharides, F4 and F5, were isolated from *C. morifolium* flowers (Zheng et al. 2006). F4 contained arabinose, galactose and galacturonic acid units in a molar ratio of 1.0:2.3:6.8 and F5 contained arabinose, rhamnose galactose and galacturonic acid units in a molar ratio of 1.0:3.2:1.0:4.3. Further, F4 had a homogalacturonan main chain with arabinogalactan side chain linked to three position of (1 \rightarrow 3,4)-linked galacturonan and F5 had a rhamnogalacturonan main chain with arabinogalactan side chain linked to 3 position of (1 \rightarrow 3,4)-linked galacturonan or 4 position of (1 \rightarrow 2,4)-linked rhamnose. Biological tests revealed that F4 and F5, two new acidic polysaccharides from the flowers, could simulate the mitogen-induced T and B lymphocyte proliferation in-vitro.

Lin and Harnley (2010) identified 46 flavonoids and 17 caffeic acid derivatives in the aqueous methanol extract of chrysanthemum (*Chrysanthemum morifolium*) flowers. The following flavonoids were identified: 6,8-C,C-diglucosylapigenin; 6-C-xylosyl-8-C-glucosylapigenin; 6-C-glucosyl-8-C-arabinosylapigenin; 6-C-arabinosyl-8-C-glucosylapigenin; luteolin 7-*O*-dihexoside; isorhamnetin 3-*O*-diglucoside; trihydroxymethoxyflavone 7-*O*-diglucoside; luteolin-*O*-glucuronylhexoside; luteolin 7-*O*-pentosylhexoside; luteolin-7-*O*-rutinoside; quercetin-7-*O*-galactoside; quercetin-3-*O*-glucoside; eriodicyol-7-*O*-glucoside; luteolin-7-*O*-glucoside; luteolin-7-*O*-glucuronide; diosmetin 7-*O*-diglucoside; apigenin-7-*O*-rutinoside; diosmetin 7-*O*-rutinoside; apigenin-7-*O*-glucoside; luteolin glucoside; diosmetin 7-*O*-galactoside; diosmetin-7-*O*-glucoside; luteolin-7-*O*-6"-malonylglucoside; quercetin glycoside; diosmetin-7-*O*-glucuronide; trihydroxymethoxyflavone glucoside; acacetin 7-*O*-diglucoside; apigenin-7-*O*-6"-malonylglucoside; luteolin-7-*O*-6"-acetylglucoside; apigenin 7-*O*-6"-acetylglucoside; diosmetin-7-*O*-6"-malonylglucoside; diosmetin-7-*O*-6"-acetylglucoside; acacetin 7-*O*-rutinoside; luteolin; acacetin-7-*O*-galactoside; acacetin 7-*O*-glucuronide;

acacetin-7-*O*-6"-malonylgactoside; apigenin; diosmetin; acacetin-7-*O*-6"-acetylgalactoside; acacetin-7-*O*-acetylgalactoside; acacetin-7-*O*-malonylacetyl-galactoside; eupatorina or chrysosplenol; chrysosplentin or its isomer; and acacetin. The following hydroxycinnamoylquinic acids were found: 1-caFFEoylquinic acid; 3-caFFEoylquinic acid; caFFEic acid 4-glucoside; chlorogenic acid; 4-caFFEoylquinic acid; 5-sinapoylquinic acid; caFFEic acid; 1,3-di-caFFEoylquinic acid; di-caFFEoylquinic acid glucoside; di-caFFEoylquinic acid glucoside; 3,4-di-caFFEoylquinic acid; 1,4-di-caFFEoylquinic acid; 1,5-di-caFFEoylquinic acid; 3,5-di-caFFEoylquinic acid; 3-methoxyoxaloyl-1,5-di-caFFEoylquinic acid; 4,5-di-caFFEoylquinic acid; 4-caFFEoyl-5-feruloylquinic acid; 4-caFFEoyl-5-feruloylquinic acid isomer; and 3,4,5-tricaFFEoylquinic acid.

Eight flavonoids vitexin-2-*O*-rhamnoside 0.10 mg/g, quercetin-3-galactoside 2.46 mg/g, luteolin-7-glucoside 50.59 mg/g, quercetin-3-glucoside 1.33 mg/g, quercitrin 21.38 mg/g, myricetin 2.13 mg/g, luteolin 5.22 mg/g, apigenin 0.70 mg/g and kaempferol 0.14 mg/g were identified in *C. morifolium* flowers (Sun et al. 2010). Fifty-eight volatiles were identified in the flowers: β -humulene 96.48 %, ledene oxide-(I) 52.96 %, *cis*- Z - α -bisabolene epoxide 36.84 %, 3,4-dihydro-2,2-dimethyl-2*H*-1-benzopyran 36.00 %, *trans*-limonene oxide 26.52 %, 2-methyl-5-(1-methylethenyl)-cyclohexanone 22.51 %, 2,6-dimethyl-1,3,6-heptatriene 19.24 %, 1,6-dibromo-hexane 18.79 %, β -elemene 16.64 %, bromo-cyclohexane 15.76 %, 1-(1,5-dimethyl-4-hexenyl)-4-methylbenzene 15.28 %, 3,3,6,6-tetraethyl-ricyclo[3.1.0.0(2,4)]hexane 15.25 %, 3-cyclohexene-1-methanol 13.29 %, 6-isopropenyl-4,8 α -dimethyl-1,2,3,5,6,7,8,8 α -octahydro-naphthalen-2-ol 12.41 %, caryophyllene 11.57 %, 1-tert-butyl-1,5-cyclooctadiene 11.49 %, 6-methyl-5-hepten-2-one 10.53 %, eicosane 9.54 %, caryophyllene oxide 9.45 %, docosane 8.90 %, 5-(1,5-dimethyl-4-hexenyl)-2-methyl-1,3-cyclohexadiene 7.80 %, bicyclo[10.1.0]tridec-1-ene 7.54 %, isoaromadendrene epoxide 7.44 %, 1,5,9,13-tetradecatetraene 7.01 %, eudesma-4(14),11-diene 6.54 %, 1*H*-cyclopropa[α]naphthalene 6.53 %, heneicosane 6.35 %, cedrol

6.29 %, (1,1-dimethylpropyl)-benzene 6.08 %, camphene 5.85 %, longifolenaldehyde 5.81 %, 3-methyl-2-cyclohexen-1-one 5.19 %, 1,7,7-trimethyl-bicyclo[2.2.1]heptan-2-one 5.03 %, *trans*- Z - α -bisabolene epoxide 5.01 %, 2,4-bis(1,1-dimethylethyl)phenol 3.03 %, β -sesquiphellandrene 2.96 %, 2,3,3-trimethyl-1-butene 2.92 %, germacrene 2.83 %, 7,11-dimethyl-3-methylene-1,6,10-dodecatriene 2.72 %, 1-methyl-4-(1-methylethylidene)-cyclohexane 2.29 %, 3,5-dimethyl-2-ethyl-1,3-cyclopentadiene 2.21 %, *cis*- α -santalol 2.21 %, 3,4,4-trimethyl-2-cyclohexen-1-one 2.14 %, spathulenol 2.10 %, α -farnesol 2.10 %, borneol 1.88 %, 1,2-benzenedicarboxylic acid, butyl octyl ester 1.75 %, 9,10-dehydro-isolongifolene 1.72 %, 1,3,3-trimethylcyclohex-1-ene-4-carboxaldehyde 1.56 %, α -farnesene 1.48 %, limonene 1.41 %, 1,8-dimethyl-4-(1-methylethyl)-spiro[4.5]dec-8-en-7-one 1.27 %, 5,5-dimethyl-1-ethyl-1,3-cyclopentadiene 1.14 %, α -pinene 1.04 %, 4-bromo-2-methyl-1-butene 0.95 %, 4-methyl-1-(1-methylethyl)-3-cyclohexen-1-ol 0.80 %, 1-(1,4-dimethyl-3-cyclohexen-1-yl)-ethanone 0.64 % and 1,7,7-trimethyl-bicyclo[2.2.1]heptan-2-ol acetate 0.60 %.

The content of flavonoid and chlorogenic acid in *C. morifolium* flowers was the highest at 70 % of full blossom, the anthocyanin at 50 % and polyphenol oxidase (PPO) activity at 30 % (Liang et al. 2007). Differences were found in phenylalanine ammonia-lyase (PAL) and peroxidase (POD) content in the two cultivars; 'huaidabaiju' had 70 and 30 %, and 'huaixiaobaiju' had 50 and 50 %, respectively. From *C. morifolium* cultivars Zaogongju, Wangongju, Huangyaoju, Chuju, Xiaoboju and Daboju, 75, 54, 78, 50, 53 and 43 components were identified, which were composed of 85.67, 82.80, 81.38, 73.22, 71.51 and 72.87 % of the total flower essential oil, respectively (Wang et al. 2008b). Monoterpenoid compounds were more abundant than sesquiterpenoid compounds in the juhua cvs Zaogongju, Wangongju, Huangyaoju, Xiaoboju and Daboju except for Chuju. There was no difference in the constituents of essential oil of Zaogongju and Wangongju; verbenyl acetate was the main chemical constituent and comprised 32.10 and 37.85 % of the total essential oil, respectively.

(1R)-camphor and bisabolol oxide A were the predominant constituents in Huangyaoju, comprising 28.70 and 12.58 % of the total essential oil, respectively. β -selinene and borneol were the major constituents in Chuju, comprising 17.85 and 12.84 % of the total essential oil, respectively. Eucalyptol (21.33 %) was the major constituent in Xiaoboju. Verbenes oxides and chrysanthenone comprised 25.32 and 8.26 % of the total essential oil, respectively, in the Daboju. The common constituents in the six cultivars of Juhua produced in Anhui province of China were camphene, borneol, bornyl acetate, (1R)-camphor, (-)-4-terpineol, α -terpineol, eucalyptol, *cis*-caryophyllene, caryophyllene oxide, juniper camphor, β -sesquiphellandrene, α -curcumene and β -farnesene. Chlorogenic acids, three *p*-coumaroylquinic acids, three feruloylquinic acids, four caffeoylquinic acids, six dicaffeoylquinic acids and two tricaffeoylquinic acids were detected, in herbal chrysanthemum samples (Clifford et al. 2007). Minor components such as five caffeoyl-hexose esters and caffeic acid-4- β -D-glucose, eight caffeoylquinic acid glycosides and 16 dicaffeoylquinic acid glycosides were also present. Succinic acid-containing chlorogenic acids and chlorogenic acids based on epi-quinic acid, previously reported in *Chrysanthemum* spp., were not detected in the samples.

Three unsaturated fatty acid isobutylamides, *N*-isobutyl-2*E*,4*E*,10*E*,12*Z*-tetradecatetraen-8-ynamide(1), *N*-isobutyl-2*E*,4*E*,12*Z*-tetradecatrien-8,10-diynamide (2) and *N*-isobutyl-2*E*,4*E*,12*E*-tetradecatrien-8,10-diynamide (3), were isolated from the leaves and flowers of *C. morifolium* (Tsao et al. 2003). The concentration of compound 1 in chrysanthemum varieties was positively correlated with host-plant resistance against the western flower thrips, *Frankliniella occidentalis*. Chlorogenic acid (5-*O*-caffeoylquinic acid); 2,3,5-*O*-dicaffeoylquinic acid; and “3,3',4',5-trihydroxyflavanone-7-*O*-glucuronide (eriodictyol-7-*O*-glucuronide) were isolated from the leaves (Beninger et al. 2004).

Aribaud and Martin-Tanguy (1994a) found that ornithine decarboxylase (ODC) regulated the polyamine putrescine biosynthesis during floral

initiation and floral development. Spermidine conjugates were predominant during floral initiation, whereas free amines did not accumulate to any significant extent. Different associations of amides were observed during floral initiation as compared with the reproductive phase. 3,4-Dimethoxyphenethylamine conjugates (water-insoluble compounds) were the predominant amine conjugates observed during flower development. Their results suggested that ODC and polyamine conjugates were involved in regulating floral initiation in *Chrysanthemum morifolium*. They also found that in fertile plants (*C. morifolium* v. Epidote), spermidine conjugates were predominant during floral initiation whereas in male-sterile plants (*C. morifolium* v. Jericho), only putrescine conjugates were detected (Aribaud and Martin-Tanguy 1994b). In both cases, ornithine decarboxylase (ODC) is involved in regulating floral initiation in normal and male-sterile plants. Huh et al. (2005) found that axillary floral bud formation and polyamine contents of nonbranching chrysanthemum were influenced by temperature. They found out that not only low temperature but also the excessively high temperature of 38 °C induced axillary bud formation. Viable axillary buds decreased remarkably at 30 and 34 °C. Exposure to 38 °C increased the putrescine contents and resulted in high putrescine/(spermidine + spermine) ratio as 22 and 26 °C. Temperature of 30 and 34 °C lowered putrescine/(spermidine + spermine) ratio. Results further showed that not polyamine contents but polyamine ratio (putrescine/spermidine + spermine) or transformation of putrescine to spermidine and spermine may be involved in the axillary bud formation in nonbranching *C. morifolium*.

C. morifolium especially the flowers have been reported to contain many phenolic compounds such as flavonoids and hydroxycinnamoylquinic acids, many of which possess a diverse array of biological characteristics such as radical scavenging and antioxidant, antiinflammatory, antiviral, anti-HIV, antimutagenic, anticarcinogenic, anti-hepatotoxic and antiaging activities

that are considered beneficial to human health (Lin and Harnley 2010).

Antioxidant Activity

Chrysanthemum flower extract was found to be rich in flavones which afforded good antioxidative activity in scavenging hydroxyl and oxygen radicals (Zhang et al. 2000). The aqueous chrysanthemum flower extract inhibited the production of free radicals and lipid peroxidation induced by free radicals in the heart and cerebral homogenate of rats (Wang et al. 2001).

Two dicaffeoylquinic acids, 3,5-dicaffeoyl-epi-quinic acid (1) and 1,3-dicaffeoyl-epi-quinic acid, isolated from *C. morifolium* showed potent superoxide anion radical scavenging activity (IC_{50} =2.9 for 1 and 2.6 μ g/ml for 2, respectively) in the xanthine/xanthine oxidase system as compared to quercetin and also showed potent DPPH radical scavenging activity (IC_{50} =5.6 for 1 and 5.8 μ g/ml for 2, respectively) (Kim and Lee 2005). The 60 % methanol flower extracts of *C. morifolium* exhibited high scavenging activities against 1,1-diphenyl-2-picrylhydrazyl (DPPH) radical as well as significant reducing power (Yang et al. 2011). This was attributed to the high total phenolic content (0.37 mg GAE/g). The methanol extract was found to contain 1.34 μ g/ml of luteolin. In another study, the methanol extract of *C. morifolium* generally showed higher total antioxidant activity than that of the ethyl acetate extract, and the petroleum ether extract hardly had any antioxidant activity (Liu et al. 2009). The cultivar Mailang exhibited the highest total antioxidant activity, but it showed slightly lower DPPH radical scavenging activity with IC_{50} value of 20.01 mg/l than that of BHT with IC_{50} value of 18.92 mg/l. Its ABTS radical scavenging activity IC_{50} value of 25.93 mg/l was about one third lower than BHT IC_{50} value of 7.72 mg/l.

Studies showed that total flavonoids from *Chrysanthemum morifolium* (TFCM) might improve antioxidant defense system, reverse lipid peroxidation and protect brain, liver and kidney against lead-induced oxidative damage in mice significantly (Xia et al. 2008). The combined

treatment of TFCM and DMSA (dimercaptosuccinic acid) could significantly lower the lead levels in blood, brain, liver and kidney and reverse lipid peroxidation and increase antioxidant enzyme levels in lead-poisoned mice dose-dependently, and it had more beneficial effects than treatment with DMSA alone. Radical scavenging activity was found to correlate with the flavonoid components in edible chrysanthemum petals (Sugawara and Igarashi 2009). Radical scavenging activity of polyphenol fractions prepared from each cultivar of *C. x morifolium* was the strongest in cv. Mottenohoka with yellow petals, followed by Kotobuki, Iwakaze and Mottenohoka with pale purple petals. Luteolin 7-*O*-(6"*O*-malonyl)-glucoside, a major flavonoid with the strongest radical scavenging activity, was the most predominant in the yellow petals of the edible chrysanthemum flower Mottenohoka.

Antitubercular Activity

Fifteen 3-hydroxy triterpenoid compounds isolated from the nonsaponifiable lipid fraction of *C. morifolium* flower extract showed a minimum inhibitory concentration (MIC) in the range of 4–64 μ g/ml, among which maniladiol (MIC 4 μ g/ml), 3-epilupeol (4 μ g/ml) and 4,5 α -epoxyhelianol (6 μ g/ml) exhibited the highest activity against *Mycobacterium tuberculosis* (Akihisa et al. 2005). Cytotoxicity of 3-epilupeol compound against Vero cells gave an IC_{50} value of over 62.5 μ g/ml, suggesting some degree of selectivity for *M. tuberculosis*.

Antimutagenic Activity

A methanol extract from *Chrysanthemum morifolium* flower heads exhibited a suppressive effect on umu gene expression of the SOS response in *Salmonella typhimurium* TA1535/pSK1002 against the mutagen 2-(2-furyl)-3-(5-nitro-2-furyl)acrylamide (furylfuramide) (Miyazawa and Hisama 2003). The ethyl acetate fraction of the flower methanol extract also showed a suppressive effect. The flavonoids

acacetin, apigenin, luteolin and quercetin isolated from the ethyl acetate fraction suppressed the furylfuramide-induced SOS response in the umu test. The ID₅₀ (50 % inhibitory dose) values of were 0.62, 0.55, 0.44 and 0.59 µmol/ml, respectively. These compounds had the suppressive effects on umu gene expression of the SOS response against other mutagens, 4-nitroquinolin 1-oxide (4NQO) and *N*-methyl-*N'*-nitro-*N*-nitrosoguanidine (MNNG), which did not require liver-metabolizing enzymes. These compounds also showed the suppression of SOS-inducing activity against the other mutagens aflatoxin B1 (Afb1) and 3-amino-1,4-dimethyl-5*H*-pyrido [4,3-*b*]indole (Trp-P-1), which required liver-metabolizing enzymes, and UV irradiation.

Anticancer Activity

Two hundred precancerous patients were treated by the herbal drug Hua-sheng-ping (containing *Chrysanthemum morifolium*, *Glycyrrhiza uralensis*, *Panax notoginseng*) (Yu 1993). The total effective rate was 95.5 % for the drug treatment compared with the control group rate of 57 %. Hydroxy taraxastane-type triterpenes, taraxasterol, heliantriol C and faradiol, isolated from the flowers showed strong inhibitory activity against 12-*O*-tetradecanoyl-phorbol-13-acetate (TPA)-induced inflammation in mice (Yasukawa et al. 1996, 1998). At 0.2 µmol/mouse, these compounds markedly suppressed the tumour promoting effect of TPA (1 µg/mouse) on skin tumour formation following initiation with 7,12-dimethylbenz[*a*]anthracene (DMBA).

All 15 pentacyclic triterpene diols and triols isolated from the flowers showed inhibitory effects against Epstein–Barr virus early antigen (EBV-EA) activation induced by the tumour promoter, 12-*O*-tetradecanoylphorbol-13-acetate, in Raji cells with potencies either comparable with or stronger than that of glycyrrhetic acid, a known natural anti-tumour promoter (Ukiya et al. 2002). Evaluation of the cytotoxic activity of six compounds, faradiol, heliantriol B0, heliantriol C, arnidiol, faradiol α-epoxide and maniladiol, against 60 human cancer cell lines revealed that

arnidiol possessed a wide range of cytotoxicity, with GI₅₀ values (concentration that yields 50 % growth) of mostly less than 6 mM. Arnidiol showed cytotoxic activity with GI₅₀ values less than 10 mM against all of the human cancer cells tested, namely, leukaemia cell lines, CCRF-CEM, HL-60 (TB), Molt-4; non-small cell lung cancer cell lines, A549/ATTC, EKVX, HOP-62, NCI-H226, NCI-H23, NCI-H322M, NCI-H522; colon cancer cell lines, COLO 205, HCT-116, HCT-15, HT29, KM12, SW-620; CNS (central nervous system) cancer cell lines, SF-268, SF-295, SF-539, SNB-19, U251; melanoma cell lines, LOX IMVI, MALME-3M, M14, SK-MEL-2, SK-MEL-28, SK-MEL-5, UACC-257, UACC-62; ovarian cancer cell lines, IGROVI, OVCAR-3, OVCAR-4, OVCAR-5, OVAR-8, SK-OV-3; renal cancer cell lines, 786-0, A498, ACHN, CAKI-1, RXF 393, SN12C, TK-10; prostate cancer cell lines, PC-3, Du-145; and breast cancer cell lines, MCF7, NCI/ADR-RES, MDA-MB-231/ATTC, HS 578T, MDA-MB-435, MDA-N, BT-549, T-47D, with two exceptions for leukaemia cells (RPMI-8226 and SR: GI₅₀, 100 mM) which were relatively insensitive to Arnidiol. Arnidiol showed significant cytotoxicity, especially against a leukaemia HL-60 cell with a GI₅₀ 0.47 mM. The cytotoxic activities of the other five compounds were not remarkable. Heliantriol C (3) (GI₅₀ value, 10.5–23.3 mM) and faradiol α-epoxide (GI₅₀, 13.7–44.0 mM) exhibited some moderate cytotoxicity for all of the cancer cells evaluated. Whereas faradiol showed marked cytotoxicity for leukaemia (CCRFCEM: GI₅₀, 3.2 mM; K-582: GI₅₀, 4.2 mM; SR: GI₅₀, 3.5 mM) and non-small cell lung cancer (EKVX: GI₅₀, 2.2 mM), it showed moderate activity for the other cells (GI₅₀, 10.5–86.9 mM). Heliantriol B0 for renal cancer (RXF 393: GI₅₀, 7.1 mM) and breast cancer (MCF7: GI₅₀, 8.4 mM) and maniladiol for renal cancer (RFX 393: GI₅₀, 7.3 mM) and breast cancer (T-47D: GI₅₀, 9.8 mM) showed some marked activity, but the other cells were relatively insensitive for these compounds (GI₅₀, 11.7–97.4 mM).

Luteolin and diosmetin isolated from the flowers exhibited significant cytotoxicities against

human colon cancer cell colon 205, with their IC_{50} values being 96.9 and 82.9 μ M, respectively (Xie et al. 2009).

Antiviral Activity

An active anti-HIV principle, acacetin-7-*O*- β -D-galactopyranoside, was isolated from *C. morifolium* (Hu et al. 1994). They found that flavonoids with hydroxy groups at C-5 and C-7 and with a C-2-C-3 double bond were more potent inhibitors of HIV growth and that the presence of substituents (hydroxyl and halogen) in the B-ring increased toxicity and/or decreased activity. A known flavone, chrysin, was found to be the most promising compound in this series. Acacetin-7-*O*- β -D-galactopyranoside from *Chrysanthemum morifolium* and chrysin, as well as apigenin-7-*O*- β -D-glucopyranoside from *Kummerowia striata*, were found to exhibit anti-HIV activity (Wang et al. 1998). Among compounds isolated from *Chrysanthemum morifolium* flowers, apigenin 7-*O*- β -D-(4''-caffeoyl)glucuronide showed strong HIV-1 integrase inhibitory activity (IC_{50} =7.2 μ g/ml) and anti-HIV activity in a cell culture assay (EC_{50} =41.86 μ g/ml) using HIV-I (IIIB) infected MT-4 cells (Lee et al. 2003).

Antimicrobial Activity

Chrysanthemum morifolium flowers afforded mixtures of the C-3 palmitate and myristate esters (3:2) of mailadiol (1), the C-3 palmitate and myristate esters (3:2) of heliantriol C (2) and fatty acid esters (1:1) of faradiol (3) and arnidol (Ragasa et al. 2005). Compound 1 exhibited moderate activity against *Aspergillus niger* and *Pseudomonas aeruginosa* and low activity against *Trichophyton mentagrophytes*, *Candida albicans* and *Bacillus subtilis*, and was inactive against *Staphylococcus aureus* and *Escherichia coli*. Compound 2 had moderate activity against *A. niger* and low activity against *P. aeruginosa* and *S. aureus* and was inactive against *B. subtilis* and *E. coli*.

Antiinflammatory Activity

The tubular flowers of *Calendula officinalis*, *Carthamus tinctorius*, *Cosmos bipinnatus*, *Chrysanthemum morifolium*, *Helianthus annuus* and *Matricaria matricarioides* showed a characteristic feature by containing helianol as the most predominant component (29–86 %) in the triterpene alcohol fractions (Akihisa et al. 1996). The triterpene alcohols from these flowers showed marked inhibitory activity against 12-*O*-tetradecanoylphorbol-13-acetate-induced inflammation in mice. Fourteen triterpene diols and triols and 9 fatty acid esters, isolated from the flowers, showed marked antiinflammatory activity against 12-*O*-tetradecanoylphorbol-13-acetate (TPA)-induced inflammation in mice with a 50 % inhibitory dose (ID_{50}) of 0.03–1.0 mg/ear, which was more inhibitive than quercetin (ID_{50} =1.6 mg/ear), a known inhibitor of TPA-induced inflammation in mice (Ukiya et al. 2001).

Hypouricemic Activity

Among 288 extracts, prepared from 96 medicinal plants used in Vietnamese traditional medicine to treat gout and related symptoms, the most active extract was the methanol flower extract of *C. sinense* with an IC_{50} value of 5.1 μ g/ml (Nguyen et al. 2004). The active constituents isolated caffeic acid, luteolin, eriodictyol and 1,5-di-*O*-caffeoylquinic acid all showed significant xanthine oxidase inhibitory activity in a concentration-dependent manner, and the activity of luteolin was more potent (IC_{50} 1.3 μ M) than the clinically used drug, allopurinol (IC_{50} 2.5 μ M). Two compounds found in the flowers, acacetin and 4,5-*O*-dicaffeoylquinic acid methyl ester, exhibited hypouricemic activity in rats pretreated with the uricase inhibitor potassium oxonate as an animal model for hyperuricemia (Nguyen et al. 2005). When administered per orally at doses of 20 and 50 mg/kg, acacetin reduced the serum uric acid level by 49.9 and 63.9 %, respectively, and the latter reduced the level by 31.2 and 44.4 %, respectively. When administered intraperitoneally

at the same doses, both of compounds exerted a dose dependent and more marked reduction of the serum uric acid level (% reduction at 20 and 50 mg/kg were 63.0 and 95.1 % in acatin, respectively, and 66.9 and 86.5 % in the dicaffeoylquinic acid methyl ester, respectively). Both compounds inhibited the rat liver xanthine oxidase activity with IC_{50} values of 2.22 and 5.27 μ M, respectively, demonstrating that the hypouricemic action of both compounds may be attributable to their xanthine oxidase inhibitory activity. From the methanol flower extract, a flavone glucoside, acacetin

7-*O*-(3-*O*-acetyl- β -D-glucopyranoside), was isolated together with 27 known compounds including flavonoids, caffeoylquinic acid derivatives, phenolics and a monoterpenoid glucoside (Nguyen et al. 2006). Compounds 1–15, 20–24 and 27 displayed significant xanthine oxidase inhibitory activity in a concentration-dependent manner, and compounds 2–11 and 22 showed more potent inhibitory activity, with IC_{50} values ranging from 0.13 to 2.31 μ M, than that of a positive control allopurinol (IC_{50} =2.50 μ M). The kinetic study indicated that 1–15 and 20–24 displayed competitive-type inhibition like that of allopurinol, while 27 displayed a mixed-type inhibition. The compounds displayed significant xanthine oxidase inhibitory activity in a concentration-dependent manner and showed potent inhibitory activity.

Aldose Reductase Inhibition Activity

The hot water extract of *Chrysanthemum morifolium* was found to have potent inhibitory activity towards lens aldose reductase (Terashima et al. 1991). Ellagic acid was isolated and found to be a potent inhibitor.

Cardioprotective Activity

Chrysanthemum indicum flower (FCI), *Chrysanthemum morifolium* flower (FCM) and *Salvia miltiorrhiza* root (RSM) extracts were found to be efficient in ameliorating the extent

and severity of the lesion in experimental myocardial infarction in the dog (Chen et al. 1983). FCI gave the best results. Experimental coronary insufficiency was also improved both in extent and severity by treating with FCI in moderate dose and with FCM, SMB and FCI in large dose. Studies showed that *Chrysanthemum morifolium* extract exhibited cardioprotective effect during ischemia/anoxia and reperfusion/reoxygenation in the isolated rat heart and the ventricular myocytes (Jiang et al. 2004). The extract (0.25–1.0 g/l) increased left ventricular developed pressure (LVDP), $\pm dp/dt(max)$, LVDP \times HR and coronary flow (CF) and decreased heart rate (HR) in a dose-dependent manner. At 0.5 g/l, it attenuated the reduction of LVDP, $\pm dp/dt(max)$ and CF caused by ischemia/reperfusion. The extract attenuated the reduction of contraction of isolated rat heart and cardiomyocytes induced by ischemia/reperfusion.

In another study, the ethyl acetate chrysanthemum extract significantly decreased the number and duration of ventricular tachycardia (VT) and delayed the occurrence of ventricular premature beats (VPB) and VT induced by aconitine compared with control rat group with experimental arrhythmia induced by aconitine (Zhang et al. 2009). Arrhythmia score of the extract group was lower than that in aconitine-treated group. The extract markedly prolonged the effective refractory period (ERP) and increased the VFT in the isolated perfused rat hearts during ischemia and reperfusion. Results suggested that the extract could reduce myocardial vulnerability and exert its antiarrhythmic effects induced by aconitine or ischemia/reperfusion, which may be related to its prolongation of action potential duration and effective refractory period that enhance the electrophysiological stability of myocardium.

Hot water chrysanthemum flower extract, ethanol flower extract and its flavonoid, apigenin and luteolin dose-dependently inhibited ICAM-1 (intercellular adhesion molecule 1) and E-selectin expression and adhesion of HL-60 (human promyelocytic leukaemia cells) by oxidised LDL

(oxLDL) (Lii et al. 2010). All of them reversed the inhibition of phosphorylation of Akt and cAMP responsive element binding protein (CREB) by oxLDL; however, this reversion was abolished by wortmannin. Their ROS scavenging capability proceeded dose-dependently in the presence of oxLDL. The results indicated that *C. morifolium* to be a plant with cardiovascular-protective potential and its inhibitory effects of on ICAM-1 and E-selectin expression were, at least partially, attributed to its antioxidant activity and modulation of the PI3K/Akt signalling pathway.

Antihypertensive Activity

Research in China reported that using about 60 g daily of *Chrysanthemum morifolium* flowers for lowering vascular pressure gave the following success rates 17.1 % very effective, 51.4 % effective and 31.5 % not effective (Zhou 1987).

Neuroprotective Activity

Chrysanthemum extract effectively inhibited the cytotoxicity induced by 1-methyl-4-phenylpyridinium ions (MPP(+)), Parkinsonian toxin and improved cell viability of SH-SY5Y neuroblastoma cells (Kim et al. 2009). The extract also attenuated the elevation of reactive oxygen species (ROS) level, increase in Bax/Bcl-2 ratio, cleavage of caspase-3 and PARP proteolysis. The results demonstrated that *C. morifolium* possessed potent neuroprotective activity and, therefore, might be a potential candidate in neurodegenerative diseases such as Parkinson's disease.

Studies showed that pretreatment of the rat brain with TFCM (total flavones extracted from *Chrysanthemum morifolium*) significantly decreased the neurological deficit scores, percentage of infarction and brain oedema and attenuated the decrease in SOD activity, the elevation of MDA content, and the generation of ROS caused by ischemia/reperfusion (I/R) injury (Lin

et al. 2010). In isolated brain mitochondria, Ca(2+)-induced swelling was attenuated by pretreatment with TFCM. The results showed that pretreatment with TFCM provided significant protection against cerebral I/R injury in rats partially by its antioxidant action and consequent inhibition of mitochondrial swelling.

Sleep Enhancement Activity

The ethanol extract of *C. morifolium* flowers was found to prolong sleep time induced by pentobarbital similar to muscimol, a GABA(A) receptor agonist (Kim et al. 2011). The extract also increased sleep rate and sleep time when administered with pentobarbital at a subhypnotic dosage. Both extract and pentobarbital increased chloride Cl⁻ influx in primary cultured cerebellar granule cells. The results suggested that chrysanthemum extract augmentation of pentobarbital-induced sleep behaviours may result from Cl⁻ channel activation. The results supported the traditional use of chrysanthemum flowers in Korea for the treatment of insomnia.

Antidiabetic and Antiaging Activities

All *C. morifolium* flower extracts (aqueous, ethanol, methanol acetone) appeared to have potent inhibitory activity towards α -glucosidase in-vitro (Yang et al. 2011). Among these, the methanol extract (IC₅₀ value of 22.0 μ g/ml) showed significantly higher inhibitory activity compared to the other extracts. Chrysanthemum was found to contain N¹,N⁵,N¹⁰,N¹⁴-tetracoumaroyl spermine, which was reported to increase the production of intracellular glutathione (Nakanishi et al. 2008 cited by Yagi et al. 2012) and inhibit the formation of AGEs (Tsuji-Naito et al. 2009; Kitano et al. 2011; Yagi et al. 2012). Among the various types of edible purple chrysanthemum varieties, the variety 'Enmeiraku' was found to contain high amounts of polyphenol, luteolin and chlorogenic acid (Kitano et al. 2011). In bovine serum albumin (BSA)/glucose (fructose) systems, both

C. morifolium and *C. indicum* strongly inhibited the formation of advanced glycation end products (AGEs) and *N*^ε-(carboxymethyl)lysine (Tsuji-Naito et al. 2009). *C. morifolium*, not *C. indicum*, also inhibited the formation of fluorescent AGEs, including pentosidine. *C. morifolium* was found to have high amounts of chlorogenic acid, flavonoid glucosides (including acetyl glucoside, neohesperidoside) and apigenin, while *C. indicum* contained large amounts of caffeic acid, luteolin and kaempferol. The results suggested the potential of both *Chrysanthemum* species for the successful treatment of conditions associated with diabetic complications and aging. In a randomized controlled double-blind clinical trial involving 35 women (48.1 ± 6.1 years, BMI 25.7 ± 1.4), the effect of edible purple chrysanthemum (*Chrysanthemum morifolium*) powder on generation of advanced glycation end products (AGEs) and the effect of oral intake of chrysanthemum on skin and serum AGEs were inconclusive (Yagi et al. 2012). However, the in-vitro experiment confirmed that chrysanthemum extracts had an anti-glycation effect. Addition of chrysanthemum powder reduced fluorescence of three F-AGEs (AGEs-derived fluorescence), in-vitro by 50 % (0.039 mg/ml, 3-deoxyglucosone (3DG); pentosidine; *N*^ε-(carboxymethyl)lysine (CML): <0.01 mg/ml) to less than or equal to the level produced by AG (F-AGEs: 0.077 mg/ml, pentosidine: >1.0 mg/ml, CML: 0.708 mg/ml).

Vasorelaxant/Vascular Smooth Muscle Activity

Studies by Jiang et al. (2001) found that the ethyl acetate extract of *C. morifolium* induced both endothelium-dependent and endothelium-independent relaxation in the rat thoracic aorta. NO and cGMP were likely involved in the endothelium-dependent relaxation, inhibition of voltage-dependent or receptor-operate Ca²⁺ channel, and activation of ATP-sensitive K⁺ channel contributed in part to the endothelium-independent relaxation by the extract.

Chrysanthemum morifolium extract was found to inhibit apoptosis of vascular smooth muscle

cells isolated from thoracic aorta of fetal calf in a concentration-dependent manner (Fang et al. 2002). The level of superoxide dismutase (SOD) was increased and the malondialdehyde (MDA) level decreased.

Antiallergic Activity

Five cultivars of *C. morifolium* flowers were found to have antiallergic activity (Xie et al. 2012). A representative medicinal cultivar, 'hua-iju', showed potential activity on the inhibition of antigen-induced degranulation from RBL-2H3 cells and compound 48/80-induced scratching in mice, whereas the in-vitro and in-vivo antiallergic activities of two edible cultivars were weak.

Anaesthetic Activity

A numbing compound *N*-isobutyl-6-(2-thienyl)-2*E*,4*E*-hexadienamide was isolated from *C. morifolium* (Shahat et al. 2001).

Pharmacokinetic Studies

Studies found that apigenin was absorbed more efficiently than luteolin into the blood plasma after oral administration of *C. morifolium* extract in rats (Chen et al. 2007). The total recovery of the dose was 37.9 % (6.6 % in urine, 31.3 % in feces) for luteolin and 45.2 % (16.6 % in urine, 28.6 % in feces) for apigenin. The cumulative luteolin and apigenin excreted in the bile was 2.05 and 6.34 % of the dose, respectively. Li et al. (2005) found that in dogs after single dose of oral administration of *C. morifolium* extract, the assay recoveries for luteolin and apigenin ranged from 102.7 to 104.5 % and 93.8–101.8 %, respectively. In eight healthy human volunteers, they found that following oral administration of tablet of *C. morifolium* extract, the assay recoveries for luteolin and apigenin were above 85.7 % (Li and Jiang 2006). The limit of quantitation was 39.20 ng/ml (*n* = 5) for luteolin and 31.45 ng/ml (*n* = 5) for apigenin in human urine. In the

pharmacokinetic experiment, *Chrysanthemum morifolium* extract dose-dependently increased plasma concentrations of retinol (vitamin A) after oral administration of retinol to rats treated with *C. morifolium* extract (Wang et al. 2012). *Chrysanthemum* also stimulated activities and expressions of CYP1A1, CYP1A2 and CYP2B1 in hepatic microsomes of rats.

Toxicity Studies

In the acute toxicity study, a single oral dose of 15 g/kg body weight (bw) *C. morifolium* ethanol extract administered to Sprague–Dawley rats caused no treatment-related death, and the maximal tolerance dose estimated was greater than 15 g/kg body weight (Li et al. 2010). In the long-term toxicity study, daily treatment by gavage at dose levels of 320, 640 and 1,280 mg/kg body weight/day caused no toxicological changes in body weight, food and water consumption, hematologic examination, blood biochemical examination, organ weight and microscopic histopathologic examination. Thus, the extract was considered to be safe in general in rats at the limited dose level.

Allergic Dermatitis Problem

Tests on sensitized guinea pigs with flowers of chrysanthemum as well as with the two sesquiterpene lactones parthenolide and alantolactone, derived from different composite species, gave positive patch test reactions with parthenolide producing stronger reactions than alantolactone (Schulz et al. 1975). Neither parthenolide nor alantolactone or pyrethrosin could be detected in *C. morifolium* extracts, but several other terpenic compounds were present which gave positive colour reactions to certain lactone reagents. Five of them showed strong positive patch test reactions in patients as well as in sensitized guinea pigs. In five patients with allergic contact dermatitis from chrysanthemum, oil of turpentine and its sensitizing compounds gave no patch test responses. A case of occupational chrysanthemum contact dermatitis was reported (Campolmi et al. 1978). Patch

tests showed the patient to be sensitized to *Chrysanthemum morifolium* leaves, flowers and stems (alcoholic extracts) and to alantolactone. The ‘maximization test’ succeeded in sensitizing guinea pigs to alantolactone. Thirty-two patients (24 male, 8 female) with contact dermatitis from *Chrysanthemum morifolium* were reported by Sharma et al. (1989). The common clinical presentations were hand and face dermatitis in 13 (41 %) and airborne contact dermatitis in 10 (31 %) patients. All 32 patients demonstrated positive patch tests to ethanol extracts of the flowers, 30 to the leaves, 28 to the whole plant, and only 6 to the stems, in that order of intensity.

Traditional Medicinal Uses

Chrysanthemum morifolium and *C. indicum* flowers have been used in traditional Chinese medicine since ancient times (Yeung 1985; Duke and Ayensu 1985; Bown 1995; Chevallier 1996). The flowers are regarded as antibacterial, antifungal, antiinflammatory, carminative, depurative, diaphoretic, febrifuge, ophthalmic, refrigerant and sedative. The flowers of *C. indicum* and *C. morifolium* (Kangiku) are listed in Japanese pharmacopeia as treatments of cephalalgia, vertigo and eye inflammation. Flowers have been used as a medication for detoxification, as an antipyretic and antiphlogistic, and for the treatment of some eye problems, such as blurred vision, itching, loss of vision, tired eyes or redness of the eyes (Kitano et al. 2011). The flowers are taken internally as a refreshing tisane to stimulate blood circulation, improve vision, soothe sore eyes, relieve headaches, counter infections and treat hypertension, chronic inflammation, dizziness, cold, coronary heart diseases and angina. Decoction of flowers is used to promote menstruation, as a wash for infected and cancerous sores and carbuncles and as poultice for enlarged glands. Flowers soaked in wine are used to restore vital functions for a variety of digestive, circulatory and nervous problems. Decoction of flowers and leaves is used for stomachache and as an enema. Leaf juice is smeared on wounds.

Other Uses

Garden chrysanthemum or Florist chrysanthemum is commonly grown as ornamental plants for their attractive, decorative and variously coloured flowers. Commercially, chrysanthemums are grown for their cut flowers, in the open or in greenhouses; they are also excellent when grown in pots as garden ornamentals. Potted chrysanthemums can be grown indoors in order to help remove toxins from the atmosphere (Wolverton 1996). It is especially good at removing chemical vapours, especially formaldehyde, benzene and ammonia.

Garden chrysanthemum are classified based on their shape, form and arrangement of the petals in the inflorescences into singles (daisy-like flower, petals radiating from flat central eye), anemones (single mums with rounded crest of deeper coloured petals), pompons (small stiff, globular flower heads), decorative (flowers with closed incurved petals or reflex petals), cushion (azalea mums growing on short bush), quills (petals straight and tubular), spider (long tubular petals with hooked ends), spoons (spoon-shaped flowers) and large-flowered (Ackerson 1957; Kofranek 1980). As a cut flower, chrysanthemum is market as either 'standard' or 'spray' form (Cockshull 1985). The standard form consists of a stem from which all but the terminal flower were removed, whereas in the spray form, the lateral flowers are kept and the terminal flower is removed.

C. morifolium has been reported to have insecticidal properties. *C. morifolium* methanol leaf extract, when incorporated into artificial diet, was found to reduce the growth of cabbage looper (*Trichoplusia ni* Hubner) larvae at concentrations between 500 and 5,000 ppm of diet (Beninger et al. 2004). Fractionation of the methanol extract gave five fractions, three of which reduced the weight of larvae relative to the control. One fraction was found to contain three main constituents, identified as chlorogenic acid (5-*O*-caffeoylquinic acid); 3,5-*O*-dicaffeoylquinic acid; and 3', 4', 5-trihydroxyflavanone-7-*O*-glucuronide (eriodictyol-7-*O*-glucuronide). At concentrations between

100 and 1,000 ppm, these compounds reduced both growth and photosynthesis of *Lemna gibba* with the order of efficacy being flavanone > chlorogenic acid > 3,5-*O*-dicaffeoylquinic acid. Further, when incorporated separately into artificial diets, these compounds, at 10–1,000 ppm, enhanced or reduced growth of the cabbage looper (*Trichoplusia ni*) and gypsy moth (*Lymantria dispar*).

Comments

Chrysanthemum (Asteraceae–Anthemideae) comprises about 40 species, most of which are distributed in East Asia, with China being the species' diversity centre (Liu et al. 2012). The Chinese *Chrysanthemum* species can be divided into two groups, the *C. zawadskii* group and the *C. indicum* group. The *C. indicum* group is distributed in southern China, mainly represented by *C. indicum* with creeping stems and small capitula with yellow ray florets. In contrast, the *C. zawadskii* group occurs in northern China, predominated by *C. zawadskii* with erect stems and large capitula with white-purple ray florets. At the diploid level, *C. lavandulifolium* and *C. nankingense* belong to the *C. indicum* group and *C. mongolicum* and *C. chanetii* are of the *C. zawadskii* group. *Chrysanthemum morifolium* is a hexaploid cultigen of complex hybrid origin, with an average chromosome number of 54 (Dowrick 1953; Langton 1989), involving probably *C. vestitum* and *C. indicum*, followed by *C. zawadskii*, *C. nankingense*, *C. lavandulifolium*, *C. lavandulifolium* var. *aromaticum* and *C. dichrum* (Chen 2012).

Chrysanthemum indicum

Scientific Name

Chrysanthemum indicum L.

Synonyms

Achillea bandana Buch.-Ham., *Achillea berdana* Buch.-Ham. ex DC., *Arctotis elegans* Thunb., *Bidens bardanna* Wall., *Bidens marginata* DC., *Chrysanthemum indicum* var. *albescens* Makino, *Chrysanthemum indicum* var. *hiberinum* Makino, *Chrysanthemum indicum* var. *indicum*, *Chrysanthemum japonicum* Thunb., *Chrysanthemum japonicum* var. *japonicum*, *Chrysanthemum koraiense* Nakai, *Chrysanthemum procumbens* Lour., *Chrysanthemum purpureum* Pers., *Chrysanthemum tripartitum* Sweet, *Dendranthema indicum* (L.) Des Moulin, *Matricaria indica* (L.) Ramat., *Pyrethrum indicum* (L.) Cass., *Tanacetum indicum* (L.) Schultz-Bip.

Family

Asteraceae

Common/English Names

Chinese Chrysanthemum, Indian Chrysanthemum, False Camomile, Garden Camomile, Ground Apple, Indian Chrysanthemum, Mother's Daisy, Roman Camomile, Whig Plant, Winter Aster

Vernacular Names

Catalan: Crisantem De L'Índia, Malabars

Chinese: Ye Ju, Ye Ju Hua, You Je

Czech: Listopadka Indická

Danish: Krysantemum

French: Chrysanthème Des Indes, Chrysanthème D'automne

Galician: Crisantemo

German: Winteraster

India: Chandramallika (**Hindi**), Sevanti (**Sanskrit**)

Japanese: Abura-Giku, Hama-Kangiku, Shima-Kangiku, Yagikka

Korean: Gamguk

Malaysia: Kekwa

Philippines: Mansanilya-A-Babasit (**Iloko**), Manzanilla (**Spanish**), Dolontas, Mansanilya (**Tagalog**)

Romanian: Floare De Toamnă, Tufănică

Spanish: Crisantelo, Crisantelmo, Crisantemo, Crisantemos, Margarita, Margaritas

Thai: Khek-Huay

Vietnam: Cúc Hoa, Cúc Hoa Vàng, Kim Cúc, Hoàng Cúc, Dã Cúc, Cam Cúc, Khỏ Ý, Biooc Kim

Origin/Distribution

The plant is indigenous to East Asia—Eastern China and central and southern Japan. It is cultivated as a medicinal plant in India, Vietnam, China and Japan and introduced into many countries as a garden ornamental. In the Philippines, it is cultivated at 1,800 m altitude in Benguet sub-province.

Agroecology

In its native range, it occurs in grasslands on mountain slopes, thickets, wet places by rivers, fields, roadsides, saline places by seashores and under shrubs from elevation of 100–2,900 m. The plant is hygrophilous and slightly shade tolerant. The plant thrives on fertile alluvial or sandy-loam soil that is well drained but sufficiently moist. It grows well in areas with temperatures of 15–30 °C and with mean annual rainfall between 1,000 and 2,000 mm.

Edible Plant Parts and Uses

In Japan, the flower heads are eaten (marinated in vinegar) (Uphof 1968; Usher 1974; Facciola 1990); in China, they are also used as a vegetable and as an aromatic plant. Dried flowers are used in mixed spices and as food additives for masking flavors, used in making an aromatic herbal tea, and used in beverages after sweetening with sugar or honey and alcoholic beverages in Korea since ancient times (Chang and Kim 2008; Chun et al. 2008). The young leaves are seasoned in combination with *Acorus gramineus*, aff. *Angelica*, *Eupatorium lindleyana*, *Sedum* aff. *sarmentosum*, and *Sedum* aff. *spectabile* and eaten cooked with chicken by the Hmong ethnic group of Vietnam (Corlett et al. 2002).

Botany

Annual or perennial herb, 25–100 cm tall with an erect, sulcate, glabrous, sparingly branched, green stem and short procumbent rhizomes. Leaves alternate, dark green above and pale green below, ovate to elliptic ovate, deeply lobed and irregularly toothed, base cuneate to truncate, apex acute, sparsely hairy to subglabrous on both sides, and on 1–2 cm long petioles (Plate 1 and 2). Inflorescence in axillary or terminal corymb of many small heads, long peduncled, 1–1.5 cm in diameter (Plates 1, 2 and 3). Involucre of many

Plate 1 Flower and foliage

Plate 2 Close up of flowering heads

Plate 3 Flowering heads being dried in the sun

elliptical bracts in 5 rows, flowers yellow, outer ray florets ligulate with 5 mm long, central disc florets tubular; corolla 2.5 mm long, obovoid and glabrous. The achenes are very small, cuneate-oblong, somewhat compressed and grooved.

Nutritive/Medicinal Properties

Flower Nutrients/Phytochemicals

Mineral elements found in the flowers were K 37.55 mg/g, P 4.8 mg/g, Ca 9.73 mg/g, Mg 3.01 mg/g, Na 0.77 mg/g, Fe 1426.63 µg/g, Mn 109.22 µg/g, Zn 58.2 µg/g, Cu 19.95 µg/g, and Mo 0.37 µg/g (Cui and Guo 2012).

Chrysanthemum indicum flowers were found to contain a sesquiterpene lactone, arteglinin-A (Hausen et al. 1975; Hausen and Schulz 1976). A sesquiterpene lactone of guaianolide-type, yejuhua lactone, was isolated from the flowers and later confirmed to be handelin (Chen and Xu 1987). The flowers contained chrysanthemoxanthine, chrysanthemin (asterin, kuromamin) luteolin glucoside, n-hexacosane, n-tetracosane, stachydrine, adenine and vitamin A (Le and Nguyen 1999). Three new eudesmane-type sesquiterpenes called kikkanols A, B, and C; flavones, luteolin and eupatilin; three flavone glycosides luteolin 7-*O*-β-D-glucopyranoside, luteolin 7-*O*-β-D-glucopyranosiduronic acid, and acacetin 7-*O*-(6 α -L-rhamnopyranosyl)-β-D-glucopyranoside; two polyacetylenes *cis*-spiroketalenolether polyne and *trans*-spiroketalenolether polyne; three sesquiterpenes clovanediol, caryolane 1,9β-diol, and oplopanone; and chlorogenic acid were isolated from the flowers (Yoshikawa et al. 1999). Five germacrane-type sesquiterpenes kikkanols D, D monoacetate, E, F, and F monoacetate and chrysanthemol (*trans*-eudesmane type sesquiterpene) were isolated from the flowers (Yoshikawa et al. 2000). Two flavanone glycosides, (2*S*)-eriodictyol 7-*O*-β-D-glucopyranosiduronic acid and (2*R*)-eriodictyol 7-*O*-β-D-glucopyranosiduronic acid, and a phenylbutanoid glycoside, (2*S*, 3*S*)-1-phenyl-2,3-butanediol 3-*O*-β-D-glucopyranoside and flavonoids: apigenin 7-*O*-β-D-glucopyranoside (apigetrin); diosmetin 7-*O*-β-D-glucopyranoside; quercetin 3,7-di-*O*-β-D-glucopyranoside; eriodictyol; (2*S*, 3*S*)-1-phenyl-2,3-butanediol, luteolin, luteolin 7-*O*-β-D-glucopyranoside; luteolin 7-*O*-β-D-glucopyranosiduronic acid; acacetin 7-*O*-

(6 α -L-rhamnopyranosyl)-β-D-glucopyranoside; and eupatilin were isolated from the flowers (Matsuda et al. 2002). From the methanol flower extract were isolated: two polyacetylenes (*cis*-spiroketalenolether polyne and *trans*-spiroketalenolether polyne), eleven sesquiterpenes (kikkanol A, kikkanol B, kikkanol C, kikkanol D, kikkanol D monoacetate, kikkanol E, kikkanol F, kikkanol F monoacetate, clovanediol, caryolane 1,9β-diol, oplopanone), ten aromatic flavonoids ((2*S*)-eriodictyol 7-*O*-β-D-glucopyranosiduronic acid, (2*R*)-eriodictyol 7-*O*-β-D-glucopyranosiduronic acid, eupatilin, luteolin, luteolin 7-*O*-β-D-glucopyranoside, luteolin 7-*O*-β-D-glucopyranosiduronic acid, apigenin 7-*O*-β-D-glucopyranoside, diosmetin 7-*O*-β-D-glucopyranoside, acatin-7-*O*-(6 α -L-rhamnopyranosyl)-β-D-glucopyranoside, quercetin 3,7-di-*O*-β-D-glucopyranoside), and two other aromatics (a phenylbutanoid glycoside (2*S*,3*S*)-1-phenyl-2,3-butanediol 3-*O*-β-D-glucopyranoside and chlorogenic acid) (Morikawa 2007).

Seven compounds were isolated 80 % ethanol flower extract: acacetin, acacetin-7-*O*-(6 α -*O*-acetyl) β-D-glucopyranoside, linarin, apigenin-7-*O*-β-D-glucopyranoside, chlorogenic acid, vanillic acid and sucrose (Gao et al. 2008). Tang et al. (2009) isolated seven compounds from the 80 % ethanol flower extract luteolin, luteolin-7-*O*-β-D-glucopyranoside, luteolin-7-*O*-(6 α -*O*-acetyl)-β-D-glucopyranoside, diosmetin, diosmetin-7-*O*-β-D-glucopyranoside, eupatilin and apigenin. Lu et al. (2009) isolated seven compounds from the flowers: acacetin, apigenin, acacetin-7-*O*-β-D-glucopyranoside, apigenin-7-*O*-β-D-glucopyranoside, luteolin, β-sitosterol and daucosterol. Thirteen compounds were isolated from the flowers, and identified as acacetin-7-*O*-β-D-glucopyranoside (1), luteolin (2), luteolin-7-*O*-β-D-glucopyranoside (3), acaciin (4), acacetin 7-*O*-(6 α -*O*-α-L-rhamnopyranosyl)-β-sophoroside (5), 3-*O*-caffeoylquinic acid (6), syringaresinol *O*-β-D-glucopyranoside (7), 5,7-dihydroxychromone (8), uracil (9), *p*-hydroxybenzoic acid (10), 4-*O*-β-D-glucopyranosyloxybenzoic acid (11), boscianin (12) and blumenol A (13) (Feng et al. 2010). Four new polyacetylenes, namely,

chrysindins A–D, together with 6 known polyacetylenes, were isolated from the flowers (Liu et al. 2011).

Twelve compounds were isolated and identified as acacetin; triclin; 2',4'-dihydroxychalcone; 5-hydroxy-4',7-dimethoxyflavon; 7-hydroxyflavonone; isorhamnetin (6),5,6,7-trihydroxy-3',4',5'-trimethoxyflanon; quercetin; (3 β , 5 α , 6 β , 7 β , 14 β)-eudesmen-3,5,6,11-tetrol; syringaresinol; liriiodendrin and genkwanin from the flowers (Wang et al. 2010a). Three germacrane-type sesquiterpene stereoisomers 1 β ,3 α ,5 β -trihydroxyl-7-isopropenyl-germacren-4(15),10(14)-diene; 1 β ,3 β ,5 α -trihydroxyl-7-isopropenyl-germacren-4(15),10(14)-diene; 1 β ,3 β ,5 β -trihydroxyl-7-isopropenyl-germacren-4(15),10(14)-diene were isolated from the flowers (Wang et al. 2012). One new disesquiterpenoid and two new sesquiterpenoids were isolated from the dried flowers (Zhou et al. 2012).

The yield of *C. indicum* flower oil was 2.0 % (w/w), and 63 volatile flavour components comprising 89.28 % of the total aroma composition were characterized (Chang and Kim 2008). The essential oil contained 35 hydrocarbons (48.75 %), 12 alcohols (19.92 %), 6 ketones (15.31 %), 3 esters (4.61 %), 5 aldehydes (0.43 %), 1 oxide (0.22 %) and 1 miscellaneous component (0.04 %). α -Pinene (14.63 %), 1,8-cineol (10.71 %) and chrysanthenone (10.01 %) were the predominant volatile components. Chang and Kim (2009) reported the yield of flower oils from Korean and Chinese gamguk were 2.0 and 0.5 % (v/w), respectively. Sixty-three volatile compounds of Korean gamguk representing 89.28 % of the total peak area were tentatively identified, including 35 hydrocarbons, 12 alcohols, 6 ketones, 3 esters, 5 aldehydes, 1 oxide, and 1 miscellaneous component. Thirty-six volatile components of Chinese gamguk constituted 58.15 % of the total volatile composition, consisting of 19 hydrocarbons, 7 alcohols, 2 ketones, 2 esters, 4 aldehydes, 1 oxide, and 1 miscellaneous component. The predominant components of Korean oil were α -pinene, 1,8-cineol, and chrysanthenone. Whereas camphor, α -curcumene, and β -sesquiphellandrene were the main aroma compounds of Chinese gamguk. Thirty-six, 63, and

55 volatiles constituents were detected in the essential oil from fresh and shade-dried and freeze-dried flowers (Choi and Kim 2011). Ketones were predominant in the volatiles of gamguk flowers: fresh, 43.8 %; shade dried, 30.3 %; and freeze dried, 36.1 %. Camphor was the most abundant volatile component; borneol was also significant. The content of camphor was higher in fresh sample than those of dried samples, while borneol concentration was significantly increased in the dried samples. Five major components of the flower essential oil are α -pinene, 1,8-cineol, chrysanthenone, germacrene-D, and α -curcumene (Kim and Lee 2009). Germacrene-D decreased by the increase of nitrogen application. However, cumambrin A contents in the flower parts were affected negatively by the increase of nitrogen application, but total yields of cumambrin A in flower parts significantly increased.

Chang et al. (2010) found 63 volatile flavour components which comprised 89.28 % of the total aroma composition of the flower oil. The predominantly abundant volatile chemical components were α -pinene (14.63 %), 1,8-cineol (10.71 %), and chrysanthenone (10.01 %). The other components included germacrene D (5.25 %), β -bisabolene (3.95 %), (–)-sinularene (3.95 %), bornyl acetate (3.64 %), β -elemene (3.18 %), borneol (3.02 %), zingiberene (2.70 %), camphor (2.64 %), terpinene-4-ol (2.41 %), filifolone (2.24 %), γ -terpinolene (2.04 %), (*E*)- β -farnesene (1.87 %), α -curcumene (1.80 %), isopinocarveol (1.55 %), sabinene (1.24 %), β -sesquiphellandrene (1.19 %), pinocarvone (1.19 %), myrcene (1.17 %) and (*E*)-chrysanthenol (1.17 %).

Wu et al. (2010a) detected 63 volatiles in the flower essential oil, and the major volatiles included 2,6,6-trimethyl-bicyclo[3.1.1]hept-2-en-4-ol (21.67 %); 2-(2,4-hexadiynylidene)-1,6-dioxaspiro[4.4]non-3-ene (21.41 %); germacrene D (6.15 %); α -neoclovene (5.10 %); eucalyptol (4.94 %); α -pinene (3.64 %); and 1,4-bis(1-methylethyl)-benzene (3.03 %). Other minor constituents included β -sesquiphellandrene (2.90 %), longipinane (2.89 %), 7, 11-dimethyl-3-methylene-1,6,10-dodecatriene (2.17 %), β -myrcene (1.78 %), caryophyllene (1.77 %),

2,6-dimethyl-6-(4-methyl-3-pentenyl)-bicyclo[3.1.1]hept-2-ene (1.71 %), 1,2,3,6-tetramethyl-bicyclo[2.2.2]octa-2,5-diene (1.64 %), 4-(1,5-dimethylhex-4-enyl)cyclohex-2-enone (1.56 %), caryophyllene oxide (1.25 %), isocyclocitral (1.23 %), cadina-1,6,8-triene (0.99 %), α,α -4-trimethyl-3-cyclohexene-1-methanol (0.84 %), 4-methylene-1-(1-methylethyl)-icyclo[3.1.0]hexane (0.74 %), 3,4-dihydro-1-naphthalene-boronic acid diethyl ester (0.71 %), borneol (0.70 %), (Z)-3,7-dimethyl-2,6-octadien-1-ol acetate (0.66 %), *trans*-3-methyl-6-(1-methylethyl)-2-cyclohexen-1-ol (0.64 %), isobornyl acetate (0.63 %), 1,3,3-trimethylcyclohex-1-ene-4-carboxaldehyde (0.60 %), butylated hydroxytoluene (0.59%), 4-methyl-1-(1-methylethyl)-3-cyclohexen-1-ol (0.57 %), (E)-3(10)-caren-2-ol (0.57 %), 2-isopropyl-5-methyl-9-methylene-bicyclo[4.4.0]dec-1-ene (0.53 %), *cis*-1-methyl-4-(1-methylethyl)-2-cyclohexen-1-ol (0.48 %), iridomyrmecin (0.37 %), benzoic acid, 2-(dimethylamino)-methyl ester (0.37 %), 6,6-dimethyl-2-methylene-icyclo[2.2.1]heptan-3-one (0.35 %), 2-methyl butanoic acid phenyl-methyl ester (0.34 %), α -caryophyllene (0.31 %), 5-ethylcyclopent-1-enecarboxaldehyde (0.31 %), camphene (0.30 %), 1,2,5,5-tetramethyl-1,3-cyclopentadiene (0.29 %), 3,7,11-trimethyl-2,6,10-dodecatrien-1-ol (0.29 %), benzyl acetoacetate (0.28 %), 3,7,11-trimethyl-1,3,6,10-dodecatetraene (0.21 %), 6,6-dimethyl-bicyclo[3.1.1]hept-2-ene-2-methanol (0.21 %), 4-dcetyl-3-carene (0.21 %), β -phellandrene (0.19 %), 1-methyl-8-(1-methylethyl)-tricyclo[4.4.0.0.2,7]dec-3-ene-3-methanol (0.18 %), copaene (0.17 %), 1,5,5-trimethyl-6-methylene-cyclohexene (0.16 %), 3,4-dihydro-2,2-dimethyl-2H-1-benzopyran (0.15 %), (S)-2-methyl-5-(1-methylethenyl)-2-cyclohexen-1-one (0.14 %), 4-methylene-2,8,8-trimethyl-2-vinyl-bicyclo[5.2.0]nonane (0.12 %), 2-n-butyl furan (0.10 %), phytol (0.10 %), 4,6,6-trimethyl-bicyclo[3.1.1]hept-3-en-2-ol (0.09 %), 1,2-diethyl-3,4-dimethyl-benzene (0.09 %), isoaromadendrene epoxide (0.08 %), 2,3-dihydro-2,2,4,6-tetramethyl-benzofuran (0.08 %), alloaromadendrene oxide-(I) (0.08 %), 4,6-dimethyl-2-pyrimidone (0.08 %), 2-methoxy-4-methyl-4-phenyl-2,5-cyclohexadien-1-one (0.07 %), tetracosane (0.07 %), hexatriac-

ontane (0.06 %), and 3,7-dimethyl-1,3,6-octatriene (0.06 %). Further, ten flavonoids (mg/g) were identified, namely, quercitrin 51.88 mg, myricetin 37.81 mg, luteolin-7-glucoside 17.24 mg, quercetin-3-galactoside 12.55 mg, quercetin-3-glucoside 9.88 mg, luteolin 7.29 mg, kaempferol 0.22 mg, vitexin 0.17 mg, rutin 0.16 mg, apigenin 0.09 mg and total flavonoids 137.29 mg (Wu et al. 2010a).

The major constituents of the essential oils from three samples fresh, air-dried and processed flowers of *Chrysanthemum indicum* were 1,8-cineole, camphor, borneol and bornyl acetate (Zhu et al. 2005). The oils also contained α -terpineol, *cis*-sabinol, thujone, terpinen-4-ol, *p*-cymene and linalool. Fresh, air-dried and processed flowers of *Chrysanthemum indicum* shared similar qualitative composition of essential oils; the difference was quantitative. The fresh flower oil had a high percentage of 1,8-cineole (30.41 %) and camphor (23.52 %), although air-dried flower oil had a high content of camphor. *Chrysanthemum indicum* essential oil also had chrysanthenone, limonene, β -caryophyllene oxide and α -pinene and β -pinene. The essential oils of dried gamguk flowers were composed of hydrocarbons (shade dried (SD) 20.1, freeze dried (FD) 21.9 %), alcohols (SD 39.7, FD 33.9 %), esters (SD 7.7, FD 7.1 %), ketones (SD 30.3, FD 36.1 %), aldehydes (SD 0.1, FD 0.4 %), oxides (SD 0.7, FD 0.1 %), acids (SD 1, FD 0.4 %), and miscellaneous ones (SD 0.4, FD 0.1 %) (Choi and Kim 2011). The oxygenated compounds were important contributors to aromatic flower flavour. Camphor (SD 28.8, FD 35.2 %) and borneol (SD 28.3, FD 24.3 %) were the most abundant volatile component of shade- and freeze-dried samples, respectively. The newly identified compounds in shade-dried sample in comparison with a fresh sample were (3E)-2,5,5-trimethylhepta-1,3,6-triene, isogeraniol, *p*-cymen-8-ol, myrtenol, *cis*-piperitol, *trans*-3(10)-caren-2-ol, 1-methyl-4-(1-methylethyl)-benzene, *trans*-piperitol, verbenene, 4-ethenyl-1,2-dimethyl-benzene, bicyclogermacrene, α -farnesene, α -muurolene, dicyclohexyl-propanedinitrile, 2,3,6-trimethyl-1,4,6-heptatriene, nerolidol, spathulenol, caryophyllene oxide, 5-ethenyl-2-methyl-pyridine, citral,

β -bisabolene, *trans*- α -bisabolene, α -gurjunene, β -eudesmol, *E*-3-phenyl-2-propenyl 3-methylbutanoate, valerenic acid, vulgarone B, aromadendrene epoxide, hexadecanoic acid, *p*-mentha-1(7)2-dien-8-ol, (*Z,Z*)-9,12-octadecadienoic acid, tricosane and pentacosane. Shade-dried gamguk flower had the greatest total number of volatile flavour compounds. α -Copaene, isobornyl-3-methylbutanoate and heptacosane were the compounds identified in only the freeze-dried sample.

Sixty-three volatile compounds of Korean gamguk representing 89.28 % of the total composition were identified, including 35 hydrocarbons, 12 alcohols, 6 ketones, 3 esters, 5 aldehydes, 1 oxide and 1 miscellaneous component (Chang and Kim 2009). Thirty-six volatile components of Chinese gamguk that constituted 58.15 % of the total volatile composition were characterized, consisting of 19 hydrocarbons, 7 alcohols, 2 ketones, 2 esters, 4 aldehydes, 1 oxide and 1 miscellaneous component. The predominant components of Korean oil were α -pinene, 1,8-cineol and chrysanthenone, whereas camphor, α -curcumene and β -sesquiphellandrene were the main aroma compounds of Chinese gamguk.

A total of 169 compounds representing 88.79–99.53 % of the oils were identified in the flower-head essential oil of 8 Chinese *C. indicum* populations (Zhang et al. 2010a). The predominant components were 1,8-cineole (0.62–7.34 %), (+)-(1*R*,4*R*)-camphor (0.17–27.56 %), caryophyllene oxide (0.54–5.8 %), β -phellandrene (0.72–1.87 %), (–)-(1*S*,2*R*,4*S*)-borneol acetate (0.33–8.46 %), 2-methyl-6-(*p*-tolyl)hept-2-ene (0.3–8.6 %), 4,6,6-trimethylbicyclo[3.1.1]hept-3-en-2-yl acetate (0.17–26.48 %), and hexadecanoic acid (0.72–15.97 %).

Leaf/Aerial Parts Phytochemicals

Mineral elements found in the leaves were K 31.52 mg/g, P 4.28 mg/g, Ca 14.14 mg/g, Mg 2.70 mg/g, Na 0.82 mg/g, Fe 1519.46 μ g/g, Mn 186.7 μ g/g, Zn 78.04 μ g/g, Cu 30.26 μ g/g and Mo 0.56 μ g/g (Cui and Guo 2012).

Mineral elements found in the stems were K 17.74 mg/g, P 1.45 mg/g, Ca 5.52 mg/g,

Mg 1.35 mg/g, Na 0.75 mg/g, Fe 433.36 μ g/g, Mn 65.84 μ g/g, Zn 76.6 μ g/g, Cu 16.34 μ g/g and Mo 0.21 μ g/g (Cui and Guo 2012).

A flavones glucoside, isolated from *C. indicum*, identified as acacetin-7-rhamnosidoglucoside was found to be identical with buddleoglucoside (Cheng et al. 1962). The sesquiterpenoid valerone was found in *C. indicum* (Uchio et al. 1981). Indicumenone, a bisabolane ketodiol, was isolated from *C. indicum* (Mladenova et al. 1987). Sesquiterpenoids, chrysetunone, chrysetunone monacetate and tunefulin were isolated from aerial parts of *C. indicum* var. *tuneful* (Mladenova et al. 1988). A sesquiterpene compound, named chrysanthetriol, was isolated from the more polar fraction of the plant (Yu et al. 1992). (3 β , 5 α , 6 β , 7 β , 14 β)-Eudesmen-3, 5, 6, 11-tetrol methanol solvate, systematic name: (3*S*,5*S*,6*R*,7*R*,10*S*)-7-(2-hydroxy-2-propyl)-10-methyl-4-methyleneperhydronaphthalene-3,5,6-triol methanol solvate, C₁₅H₂₆O₄·CH₄O, a new sesquiterpenoid was isolated from *C. indicum* (Wang et al. 2006). Twelve compounds were obtained from *C. indicum* fraction with cardiovascular activity and identified as (2*S*)-eriodictyol-7-*O*- β -D-glucuronide (1), (2*S*)-eriodictyol-7-*O*- β -D-glucoside (2), (2*S*)-esperetin-7-*O*- β -D-glucuronide (3), luteolin-7-*O*- β -D-glucoside (4), luteolin-7-*O*- β -D-glucuronide (5), diosmetin-7-*O*- β -D-glucuronide (6), quercetin-7-*O*- β -D-glucoside (7), (2*S*)-eriodicticaffeoylquinic acid (8), 3,5-dicaffeoylquinic acid (9), 3,5-*cis*-dicaffeoylquinic acid (10), 1,5-dicaffeoylquinic acid (11) and 1,3-dicaffeoylquinic acid (12) (Sun et al. 2012). The following compounds were isolated from the methylene chloride fraction of *C. indicum* crude ethanol extract: sudachitin, hesperetin, chrysoeriol and acacetin (Kim et al. 2013).

Seventy-three compounds accounting for 96.65 % of the extracted essential oil of the aerial parts were identified (Jung 2009). The oil comprised 14.88 % monoterpene hydrocarbons (MH), 52.14 % oxygenated monoterpenes (OM), 22.9 % sesquiterpene hydrocarbons (SH), 5.97 % oxygenated sesquiterpenes (OS) and 0.75 % others (O). The main compounds in the oil were α -pinene (4.4 %, MH), 1,8-cineole (10.4 %, OM), α -thujone (6.05 % OM), camphor (10.12 %, OM),

bornyl acetate (6.1 % OM), borneol (3.6 % OM), terpinen-4-ol (3.4 % OM), *cis-chrysanthenol* (3.4 % OM), β -caryophyllene (5.1 %, SH), germacrene D (10.6 %, SH) and α -cadinol (3.0 %, OS). The minor components included monoterpene hydrocarbons (tricyclene, α -thujene, camphene, β -pinene, sabinene, myrcene, α -terpinene, limonene, α -phellandrene, *cis*- β -ocimene, γ -terpinene, *trans*- β -ocimene, *p*-cymene, terpinolene), oxygenated monoterpenes (α -terpinolene, *cis*-3-hexen-1-ol, β -thujone, *trans*-sabinene hydrate, chrysanthenone, linalool, pinocavone, *cis*-chrysanthenyl acetate, umbellulone, *trans*-chrysanthenyl acetate, *trans*-piperitol, α -terpineol, piperitone, carvone, myrtenol, *trans*-carveol, *p*-cymen-8-ol, *cis*-carveol), sesquiterpene hydrocarbons (α -copaene, α -gurjunene, berkheyaradulen, β -elemene, α -humulene, *trans*- β -farnesene, α -muurolene, γ -cadinene, α -zingiberene, β -selinene, *cis*, *trans*- α -farnesene, δ -cadinene, β -sesquiphellandrene, *ar*-curcumene), oxygenated sesquiterpenes (caryophyllene oxide, *trans*-nerolidol, globulol, guaial, spathulenol, eugenol, α -cedrol, torreyol, T-muurolol, *cis*-*trans*-farnesol), and others (1,2,4 trimethylbenzene, *n*-hexanol, 1-octen-3-ol, tricosane, tetracosane). Steam distilled oil from the flowers, leaves and total aerial parts contained borneol, chrysanthenone and bornyl acetate as the major components (Stoianova-Ivanova et al. 1983).

A water-soluble neutral polysaccharide (CIP-C) was obtained from *Chrysanthemum indicum* (Jin et al. 2012). CIP-C was found to be a neutral branched heteropolysaccharide, mainly composed of D-Man, D-Glc and D-Gal, with a small quantity of D-Fuc, L-Ara and D-Xyl. The backbone of CIP-C was linked by β (or α)-D-1,4-Man, β -D-1,6-Glc and β -D-1,4-Gal. In addition, T-Araf, 1,5-Araf and T-Gal, 1,4-Gal, 1,3,6-Gal, 1,3,4,6-Gal may be linked as an arabinan branch and an AGI arabino-galactan branch.

Root Phytochemicals

Mineral elements found in the roots were K 15.84 mg/g, P 1.25 mg/g, Ca 10.10 mg/g, Mg 2.54 mg/g, Na 3.16 mg/g, Fe 3219.90 μ g/g, Mn 144.33 μ g/g, Zn 227.50 μ g/g, Cu 64.60 μ g/g and Mo 0.22 μ g/g (Cui and Guo 2012).

Antioxidant Activity

The water extract of gamguk teas did not differ significantly in yield compared to methanol extracts and showed stronger antioxidant activity (Eom et al. 2008). Catechin contents in gamguk teas were 8–18 % of the extracts. Gamguk teas exhibited faster release of antioxidants, and the antioxidant activity was positively correlated with the thermal treatments. Gukhwacha was the best tea for rapid release (30 seconds) of antioxidants with the 50 °C treatment, whereas antioxidants in other teas were relatively slower.

Anticancer Activity

Chrysanthemum indicum extract inhibited proliferation of human hepatocellular carcinoma (HCC) MHCC97H cells in a time- and dose-dependent manner without cytotoxicity in rat hepatocytes and human endothelial cells (Li et al. 2009). The extract CIE exerted a significant apoptotic effect through a mitochondrial pathway and arrested the cell cycle by regulation of cell cycle-related proteins in MHCC97H cells without an effect on normal cells. Yuan et al. (2009) found that *C. indicum* extract was effective in attenuating the mitogenic effect of isoproterenol on both HepG2 and MHCC97H human hepatocellular carcinoma cells. The inhibitory effect of the extract was mediated by inhibiting the isoproterenol-induced activation of MAPK/ERK1/2 via β 2-AR in tumour cells. In further studies, they found that *C. indicum* ethanol extract reduced MHCC97H cell metastatic capability, in part at least, through decrease of the MMP-2 and MMP-expression with a simultaneous increase of the TIMP-1 and TIMP-2 expression thus restoring their balance in the cancer cells (Wang et al. 2010b). Five Chinese herbs (*Curcuma wenyujin*, *Chrysanthemum indicum*, *Salvia chinensis*, *Ligusticum chuanxiong* and *Cassia tora*) were found to sensitize resistant cancer cells at a nontoxic concentration (10 μ g/ml) and markedly increased doxorubicin accumulation in multidrug-resistant human breast cancer MCF-7/ADR cells (Yang et al. 2011b). Fractions from CH_2Cl_2 extracts were more effective than fractions

from ethyl acetate extracts. Fractions from *Curcuma wenyujin* and *C. indicum* exhibited significant effects in sensitization of these resistant MCF-7/ADR cancer cells at nontoxic concentration to doxorubicin and docetaxel (Yang et al. 2011a). All the fractions could enhance the apoptosis induced by doxorubicin in MCF-7/ADR cells and restore the effect of docetaxel on the induction of G2/M arrest in A549/Taxol cells. The fractions also had to induce S-phase arrest.

The methylene chloride fraction of *C. indicum* crude ethanol extract exhibited strong cytotoxic activity as compared with the other fractions and clearly suppressed constitutive STAT3 activation against both human prostate cancer DU145 and U266 cells, but not human breast cancer MDA-MB-231 cells (Kim et al. 2013). It was found that the fraction could induce apoptosis through inhibition of the JAK1/2 and STAT3 signaling pathways. Furthermore, the major components of the fraction were bioactive compounds such as sudachitin, hesperetin, chrysoeriol and acacetin. Sudachitin, chrysoeriol and acacetin also exerted significantly cytotoxicity, clearly suppressed constitutive STAT3 activation, and induced apoptosis, although hesperetin did not show any significant effect in DU145 cells.

Antimicrobial Activity

C. indicum essential oil exhibited antibacterial activities against both *Staphylococcus aureus* and *Escherichia coli* (Aridoğan et al. 2002). The antimicrobial activity of essential oils from air-dried and processed flowers was evaluated against 15 microorganisms including 3 yeasts (Zhu et al. 2005). The results showed that both essential oils possessed significant antimicrobial effect; however, some difference in antimicrobial activity between two oils was observed for several microorganisms, which was attributed to the variation in percentage of the components. Antibacterial activities of the essential oils were exhibited against *Staphylococcus aureus* and *Escherichia coli*. With higher percentage of camphor, the oil of the processed flowers exhibited, in many cases, greater bacteriostatic activity than that of the air-dried ones.

The essential oil of *C. indicum* exhibited moderate activities against most of tested streptococci species (*Streptococcus pyogenes*, *S. mutans*, *S. sanguinis*, *S. sobrinus*, *S. rattii*, *S. creceti*, *S. anginosus*, *S. gordonii*) (MICs, 0.2–0.8 mg/ml; MBCs, 0.4–1.6 mg/ml) (Jung 2009). The oil also showed a strong antimicrobial activity against obligate anaerobic bacteria: *Fusobacterium nucleatum*, *Prevotella intermedia* and *Porphyromonas gingivalis* (MICs, 0.1–0.2 mg/ml; MBCs, 0.2–0.8 mg/ml). The major components of the essential oil from *C. indicum*, terpinon-4-ol, borneol and β -caryophyllene, were indicated as stronger antibacterial activity than α -pinene, camphor and 1,8-cineole. In combination with the essential oil, the MICs/MBCs for ampicillin and gentamicin were reduced by ≥ 8 -fold in tested some of oral bacteria and reference bacteria, suggesting a synergistic effect.

C. indicum leaf volatile oil exerted maximum antibacterial activity against *Pseudomonas aeruginosa* at a concentration of 1 %v/v followed by against *Micrococcus luteus* in comparison with erythromycin as standard antibacterial agent (Pradhan et al. 2011). The volatile oil also exhibited antifungal activity against *Candida albicans* at the same concentration of 1 %v/v, when compared with ketoconazole as standard antifungal agent.

Antiinflammatory Activity

The methanol extract and ethyl acetate-soluble portion from the flowers of *Chrysanthemum indicum* were found to show inhibitory activity against nitric oxide (NO) production in lipopolysaccharide-activated macrophages with potent inhibitory activity shown by the acetylenic compounds and flavonoids from the ethyl acetate-soluble portion (Yoshikawa et al. 2000). Two acetylenic compounds, *cis*-Spiroketalenolether polyne and *trans*-spiroketalenolether polyne, and two flavones, luteolin and eupatilin, were found to inhibit nitric oxide production in mouse peritoneal macrophages. Chrysanthemol, a *trans*-eudesmane-type sesquiterpene from *Chrysanthemum indicum*, also possessed antiinflammatory activity (Mou et al. 2001). Studies

showed that the *C. indicum* inflorescence extract (butanol fraction) possessed antiinflammatory, humoral and cellular immunomodulatory and mononuclear phagocytic activities, probably due to the presence of flavonoids (Cheng et al. 2005). At a dose of 150 mg/kg, p.o., the butanol-soluble fraction exhibited significant inhibition of auricle edema in mice. Delayed-type hypersensitivity reaction induced by 2,4-dinitro-fluorobenzene was significantly enhanced by the butanol extract (150 and 300 mg/kg, p.o.) as was antibody generation by splenic cells of mice and IgG and IgM levels in mice sera in response to sheep red blood cells in cyclophosphamide-induced mice. Both these doses potentiated the function of the mononuclear phagocytic system in cyclophosphamide-induced mice.

Separate studies on synoviocytes isolated from the knee joints of rats showed that the total flavonoids of *Chrysanthemum indicum* (TFC) could induce synoviocytes apoptosis and suppress proliferation of synoviocytes in Freund's complete adjuvant-induced arthritis rats (Chen et al. 2008). Further studies in adjuvant arthritis rat model showed that TFC inhibited the proliferation of synovial and induced the apoptosis of synovium and synoviocytes in-vivo in a dose-dependent way and thereby exerted therapeutical effect on rheumatoid arthritis (Xie et al. 2008). Total flavonoids of *C. indicum* extract showed significant therapeutical effect on adjuvant arthritis in adjuvant arthritis rats, and its mechanism was at least in part related to the antioxidant and immunoregulatory effects (Zhang et al. 2010b). The extract decreased the levels of MDA and NO and increased the activity of SOD in serum and supernatant of peritoneal macrophage. Also the suppressed lymphocyte proliferation and IL-2 production of splenic lymphocytes in AA rats were reversed by treatment with the extract.

Studies found 70 % ethanol extract from *Chrysanthemum indicum* to be an effective anti-inflammatory agent in murine phorbol ester-induced dermatitis, suggesting that the extract may have therapeutic potential in a variety of immune-related cutaneous diseases (Lee et al. 2009). The extract caused substantial reductions in skin thickness and tissue weight, inflammatory

cytokine production, neutrophil-mediated myeloperoxidase activity and various histopathological indicators. The extract was also effective at reducing inflammatory damage induced by chronic 12-*O*-tetradecanoyl-phorbol-13-acetate (TPA). Further studies showed that the anti-inflammatory properties of *C. indicum* ethanol flower extract in lipopolysaccharide-induced RAW 264.7 macrophages might result from the inhibition of inflammatory mediators, such as NO, prostaglandin E2 (PGE2), TNF-alpha (tumour necrosis factor alpha) and IL-1beta (interleukin-1beta), via suppression of mitogen-activated protein kinases (MAPKs) and NF-kappa B (nuclear factor kappa B)-dependent pathways (Cheon et al. 2009). The results indicated that the extract may have therapeutic potential in a variety of immune-related cutaneous diseases.

Studies showed that at 1, 10 and 100 µg *C. indicum* extract inhibited cell loss, decreased the reactive oxygen species production, regulated the Bax/Bcl-2 ratio, and inhibited poly (ADP-ribose) polymerase (PARP) proteolysis in 1-methyl-4-phenylpyridinium ion (MPP(+))-induced SH-SY5Y cells (Kim et al. 2011a). Moreover, the extract suppressed the production of prostaglandin E(2), expression of cyclooxygenase type-2 (COX-2), blocked IκB-α degradation and activation of NF-κB p65 in BV-2 cells in a dose-dependent manner. The activity of the extract might involve its inhibitory actions both on neuronal apoptosis and neuroinflammatory NF-κB/IκB-α signaling pathway. In-vitro studies found that 70 % ethanol extract of *Chrysanthemum indicum* strongly inhibited Epstein-Barr virus (EBV) latent infection membrane protein 1 (LMP1)-induced activation of NF-κB and the viability of EBV-transformed lymphoblastoid cell lines (Kim et al. 2012).

A traditional Chinese medicine (TCM) recipe named CPZ comprising extracts of *Chrysanthemum indicum*, *Pogostemon cablin* and *Curcuma wenyujin* was found to possess potent antiinflammatory activity, which was indicated to be closely associated with its upregulation on interleukin IL-1β and downregulation of prostaglandin E(2) in the edema paw tissue of rats (Su et al. 2012).

Hypouricemic Activity

In a study, a total of 122 traditional Chinese medicinal plants were selected according to the clinical efficacy and prescription frequency for the treatment of gout and other hyperuricemia-related disorders and were evaluated for inhibitory activity of the xanthine oxidase enzyme that catalyses the oxidation of hypoxanthine to xanthine and then to uric acid, which plays a crucial role in gout (Kong et al. 2000). The methanol extract of *C. indicum* exhibited inhibitory effect on xanthine oxidase activity with an IC_{50} of 22 $\mu\text{g/ml}$ and ranked second to *Cinnamomum cassia* twig (IC_{50} 18 $\mu\text{g/ml}$) thus providing a basis for the use of this medicinal plant for gout treatment.

Hemodynamic/Cardiovascular Activity

An aqueous extract of *Chrysanthemum indicum* flower directly and uniformly produced coronary and systemic vasodilation action and a renal vasoconstricting action in the open-chest dog, and the pharmacological profile of the flower extract was in part similar to that of adenosine (Kato et al. 1986). Intravenous administration of the aqueous extract (5–20 mg/kg) produced a decrease in aortic blood pressure and increases in coronary blood flow, left ventricular dP/dt (change in pressure/change in time) and heart rate in a dose-dependent manner, while renal blood flow was initially decreased and then increased to the values above the preinjection level. Dipyrindamole (0.1 mg/kg i.v.) potentiated an increase in coronary blood flow of the extract and aminophylline (1.0 mg/kg i.v.) attenuated this response. A two-fold increase in coronary blood flow was elicited by the aqueous extract (13.8 mg/kg) and by adenosine (29.5 $\mu\text{g/kg}$). Intravenous administration of the flower extract (5–20 mg/kg) as well as adenosine (10–50 $\mu\text{g/kg}$) produced decreases in aortic blood pressure and renal blood flow and increases in aortic blood flow, vertebral blood flow, coronary blood flow and left ventricular dP/dt (Kato et al. 1987). Calculated coronary, vertebral and total peripheral

resistances were decreased by the extract or adenosine in a dose-dependent manner. The results indicated that *C. indicum* extract directly and uniformly produced coronary and systemic vasodilation with renal vasoconstriction and that adenosine directly produced vasoconstriction in renal vasculature and vasodilation which was more potent in coronary vasculature than in systemic ones.

Sun et al. (2012) found that flavonoids, namely, (2*S*)-eriodict-dicaffeoylquinic acid; 3,5-dicaffeoylquinic acid; 3,5-*cis*-dicaffeoylquinic acid; 1,5-dicaffeoylquinic acid; and 1,3-dicaffeoylquinic acid, were the major components of the active fraction of *C. indicum* that exhibited cardiovascular activity.

Antidiabetic and Antiaging Activities

In bovine serum albumin (BSA)/glucose (fructose) systems, both *C. morifolium* and *C. indicum* strongly inhibited the formation of advanced glycation end products (AGEs) and *N*^ε-(carboxymethyl)lysine (Tsuiji-Naito et al. 2009). *C. morifolium*, not *C. indicum*, also inhibited the formation of fluorescent AGEs, including pento-sidine. *C. morifolium* was found to have high amounts of chlorogenic acid, flavonoid glucosides (including acetyl glucoside, neohesperidoside), and apigenin, while *C. indicum* contained large amounts of caffeic acid, luteolin and kaempferol. The results suggested the potential of both *Chrysanthemum* species for the successful treatment of conditions associated with diabetic complications and aging.

Aldose Reductase Inhibitory Activity

Two new flavanone glycosides, (2*S*)-eriodictyol 7-*O*- β -D-glucopyranosiduronic acid (1) and (2*R*)-eriodictyol 7-*O*- β -D-glucopyranosiduronic acids (2), and a new phenylbutanoid glycoside, (2*S*, 3*S*)-1-phenyl-2,3-butanediol 3-*O*- β -D-glucopyranoside, were isolated from *Chrysanthemum indicum* flowers, and (1) and (2) exhibited potent inhibitory activity for rat lens aldose reductase

(Matsuda et al. 2002). However, the inhibitory activities of 1 and 2 were weaker than those of luteolin and luteolin 7-*O*- β -D-glucopyranoside which were also isolated from the flowers of *C. indicum* by Yoshikawa et al. (1999). Aldose reductase is a key enzyme in the polyol pathway that catalyses the reduction of glucose to sorbitol. Accumulation of sorbitol has been implicated in the chronic complications of diabetes such as cataract. The methanol extract of the flower extract exhibited inhibitory activity against rat lens aldose reductase (Yoshikawa et al. 1999). From the methanol flower extract, active components such as flavone and flavone glycosides were isolated by bioassay-guided separation using aldose reductase inhibitory activity together with three new eudesmane-type sesquiterpenes called kikkanols A, B and C. The flavone, luteolin, three flavone glycosides (luteolin 7-*O*- β -D-glucopyranoside, luteolin 7-*O*- β -D-glucopyranosiduronic acid, acacetin 7-*O*-(60- α -L-rhamnopyranosyl)- β -D-glucopyranoside), and chlorogenic acid were potent inhibitors of rat lens aldose reductase, but their activity was weaker than that of a commercial synthetic aldose reductase inhibitor, epalrestat. Another flavone, eupatilin, and two sesquiterpenes (clovanediol, caryolane 1,9 β -diol) exhibited less activity than luteolin and the three flavone glycosides. Other sesquiterpenes (kikkanol A, kikkanol C, oplopanone) and two polyacetylenes (*cis*-spiroketalenoether polyne, *trans*-spiroketale-noether polyne) exhibited little activity.

Antidermatitis Activity

Topical application *Chrysanthemum indicum* to mice with atopic dermatitis-like skin lesions in 2,4-dinitrochlorobenzene (DNCB)-treated NC/Nga mice dose dependently reduced severity of clinical symptoms of dorsal skin, ear thickness and the number of mast cells and eosinophils (Park et al. 2012). *C. indicum* (30 %) significantly decreased serum IgE, IgG1, IL-4 and IFN- γ levels and reduced mRNA levels of interferon IFN- γ , interleukins IL-4 and IL-13 in dorsal skin lesion. The results suggested that *C. indicum* may be an effective alternative for the management of atopic dermatitis.

Nephroprotective Activity

Chrysanthemum indicum extract protected human proximal tubular HK-2 cells against cisplatin-induced apoptosis by its antioxidant activity against hydrogen peroxide and hydroxyl radical (Pongjit et al. 2011). In addition, the extract renal cells without significant interfering effect on cisplatin toxicity in lung cancer H460 and melanoma G361 cells.

Neuroprotective Activity

Chrysanthemum indicum was found to possess neuroprotective activity (Chun et al. 2008). It had been recorded as having therapeutic effects for stroke in Korean traditional medicine. Its aqueous extract significantly increased the cell viability of SK-N-SH human neuroblastoma cells exposed to oxygen-glucose deprivation both in-vitro and in-vivo cerebral ischemia models.

Radioprotective Activity

Chrysanthemum indicum flowers were reported being able to absorb ultraviolet and cure sunburn (Huang et al. 2004). It has potential to be a natural additive in health protection cosmetic.

Hepatoprotective Activity

Chrysanthemum indicum was one of the nine Chinese herbal medicine with hepatoprotective and antioxidant activity, inhibiting lipid peroxidation in a dose-dependent manner thereby protecting liver function (Jiang et al. 1997).

Antithrombotic Activity

Studies by Levy and Xie (1988) reported that the aqueous extract of *Chrysanthemum indicum* flowers was 10–12 times more potent on platelet-activating factor (PAF)-induced aggregation of human platelet-rich plasma compared to ADP (adenosine diphosphate) aggregation of rat

platelet-rich plasma providing partial evidence in support of the traditional use of *Chrysanthemum indicum* in the treatment or prevention of thrombosis.

Cardioprotective Activity

Li (1981) reported that *C. indicum* extract protected injured neonatal rat heart cells by reducing the release of lactate dehydrogenase (LDH) from injured heart cells deprived of oxygen and glucose. Further 10^{-5} M propranolol showed similar protective effect, while 10^{-4} M isoprenaline exacerbated heart cell injury.

Chrysanthemum indicum flower (FCI), *Chrysanthemum morifolium* flower (FCM) and *Salvia miltiorrhiza* root (RSM) extracts were found to be efficient in ameliorating the extent and severity of the lesion in experimental myocardial infarction in the dog (Chen et al. 1983). FCI gave the best results. Experimental coronary insufficiency was also improved both in extent and severity by treating with FCI in moderate dose and with FCM, SMB and FCI in large dose. In another study, after 7–9 days of treatment, *C. indicum* significantly reduced the left ventricular weight index and heart weight index in mice and rats with myocardial hypertrophy induced by isoprenaline and L-thyroxine, decreased the content of angiotensin II in ventricular tissue in mice and rats, and reduced the ALD, TNF-alpha concentration in serum, and the hydroxy proline content in ventricular tissue in rats (Wu et al. 2010b).

Antihypertensive Activity

An active fraction from the hot ethanol extract of *C. indicum* was found to lower blood pressure in anaesthetized cats and normotensive dogs (Liu et al. 1962). Four normotensive dogs fed 50, 100, 130 and 150 mg/kg of the fraction, registered diastolic pressure decline of 0, 24, 8 and 36 mmHg, respectively. Weekly tests on EKG (electrocardiogram), serum BSP (bone sialoprotein)

retention and blood NPN (nonprotein nitrogen) revealed no serious alterations when three renal hypertensive dogs were fed daily 100 mg/kg in the first 2 weeks and 200 mg/kg for the third week.

Antinociceptive/Analgesic Activity

The petroleum ether fraction from the ethanol extract of flowers and buds administered orally at doses of 188 and 376 mg/kg to mice produced significant inhibitions on chemical nociception induced by intraperitoneal acetic acid, subplantar formalin or capsaicin injections and on thermal nociception in the tail-flick test and the hot plate test (Shi et al. 2011). In the pentobarbital sodium-induced sleep time test and the open-field test, the flower fraction neither enhanced the pentobarbital sodium-induced sleep time nor impaired the motor performance, indicating that the observed antinociception was unrelated to sedation or motor abnormality. The fraction did not affect temperature within 80 minutes. The results suggested that petroleum ether flower fraction-produced antinociception might involved ATP-sensitive K^+ channels and the mAChRs-ATP-sensitive K^+ channels pathway. The aqueous fraction of an ethanol *C. indicum* extract administered orally to mice produced analgesic activity in the chemical nociception induced by intraperitoneal acetic acid, subplantar formalin/capsaicin injections model and in the thermal nociception in the tail-flick test and in the hot plate test (Chen et al. 2011). In the pentobarbital sodium-induced sleeping time test and the open-field test, the aqueous fraction neither significantly enhanced the pentobarbital sodium-induced sleeping time nor impaired the motor performance, indicating that the observed analgesic activity was unlikely due to sedation or motor abnormality. Moreover, the effective dose (600 mg/kg) also showed no toxicity within 7 days. The results suggested the analgesic activity possibly related to the flavonoid glycosides and phenolic glycosides in the fraction.

Otoprotective Activity

Studies found that Chungshinchongyitang (CSCYT), an herbal drug formula containing *Chrysanthemum indicum* and 13 other herbs, prevented the destruction of hair cell arrays induced by cadmium in the rat organ of Corti primary explants (Kim et al. 2011b). CSCYT inhibited cell death, release of cytochrome C, and generation of reactive oxygen species induced by cadmium in HEI-OC1 auditory cell line. Further, it was demonstrated that CSCYT exerted its effect by modulating apoptosis via the caspase-3 activation and extracellular signal-regulated kinase activation. CSCYT is used in Korean medicine for treating auditory diseases.

Antiosteoporotic Activity

Gamuk flower oil was found to increase the collagen, alkaline phosphatase activity and mineralization of osteoblasts (MC3T3-E1 cells) significantly, indicating that 'gamguk' may help in the treatment of osteoporosis (Chang et al. 2010). *Chrysanthemum indicum* extract (100 µg/ml) significantly increased the growth of osteoblastic MC3T3-E1 cells and caused a significant elevation of alkaline phosphatase (ALP) activity and the deposition of collagen and calcium in the cells (Yun et al. 2011). This activity was completely prevented by the presence of 1 µM tamoxifen, suggesting that the extract's effect might be partly involved in estrogen-related activities. The results indicated that the enhancement of osteoblast functionality by *C. indicum* may prevent osteoporosis and inflammatory bone diseases.

Antidiabetic and Antiaging Activities

In bovine serum albumin (BSA)/glucose (fructose) systems, both *C. morifolium* and *C. indicum* strongly inhibited the formation of advanced glycation end products (AGEs) and *N*^ε-(carboxymethyl)lysine (Kentaro et al. 2009). *C. morifolium*, not *C. indicum*, also acted to inhibit the formation of fluorescent AGEs, including

pentosidine. *C. morifolium* was found to large amounts of chlorogenic acid, flavonoid glucoside varieties and apigenin, while *C. indicum* contained large amounts of caffeic acid, luteolin and kaempferol. The results suggested the potential of both *Chrysanthemum* species for the successful treatment of pathogenesis in conditions associated with diabetic complications and aging.

Antiplasmodial Activity

The leaf extracts of *Aristolochia indica* (IC₅₀ 10 µg/ml), *Cassia auriculata* (IC₅₀ 14 µg/ml), *Chrysanthemum indicum* (IC₅₀ 20 µg/ml) and *Dolichos biflorus* (IC₅₀ 20 µg/ml) showed promising activity against blood stage chloroquine-sensitive and chloroquine-resistant strains of *Plasmodium falciparum* (Kamaraj et al. 2012). The high TC₅₀ in mammalian cell cytotoxicity assay and the low IC₅₀ in antimalarial *P. falciparum* assay indicated selectivity and good resistance indices in the range of 0.9–1.7 for leaf extracts of *A. indica*, *C. auriculata*, *C. indicum* and *D. biflorus*, suggesting that these may serve as antimalarial agents even in their crude form.

Larvicidal Activity

Among three plant extracts (*Annona squamosa*, *Chrysanthemum indicum* and *Tridax procumbens*) tested, the ethyl acetate leaf extract of *C. indicum* exhibited highest toxic effect (LC₅₀=39.98 mg/l) against larvae of malaria vector, *Anopheles subpictus* and the methanol leaf extract against the larvae of Japanese encephalitis vector, *Culex tritaeniorhynchus* (LC₅₀=42.29 mg/l) (Kamaraj et al. 2011).

Allergy Problem

Of 12 fractions obtained from *C. indicum* dried flower extract, four fractions gave on epicutaneous application to guinea pigs sensitized with an extract of *C. indicum* (Hausen and Schulz 1976). One of these allergens was identified as a sesquiterpene lactone, Arteglasin-A of the guaianolide-type.

Traditional Medicinal Uses

C. indicum has a long history of use as an Oriental traditional medicine for the treatment of several infectious diseases such as pneumonia, colitis, stomatitis, cancer, fever and sores and used to treat vertigo, pertussis, inflammatory diseases, intoxication, respiratory ailments, hypertension and hypotensive symptoms (Stuart 1979; Duke and Ayensu 1985; Yeung 1985; Yu et al. 1992; Jiang et al. 1997; Corlett et al. 2002; Matsuda et al. 2002; Cheng et al. 2005; Zhu et al. 2005; Morikawa 2007; Chun et al. 2008; Chen et al. 2008; Cheon et al. 2009; Jin et al. 2012). Various parts of the plant have been used in traditional medicine in India and Southeast Asia (CSIR 1950; Burkill 1966; Kirtikar and Basu 1975; Chopra et al. 1986; Le and Nguyen 1999; Stuart 2012). In traditional Chinese medicine, the whole plant is antiphlogistic, blood tonic, aperient, antipyretic, depurative, febrifuge and vulnerary, and the plant is used to treat eye ailments. *Chrysanthemum indicum* is a common traditional herbal medicine used for the treatment of inflammation, hypertension and respiratory diseases due to its strong antagonistic function against inflammatory cytokines (Yun et al. 2011). In India, the plant is used in conjunction with black pepper for treating gonorrhoea and affections of the brain, calculi, as well as antidote for mental depression. The plant is used in ointments used for bruises, sprains and calluses. In Malaya, the plant is used for colds and headaches and as a poultice for sores and infused in spirits as a digestive. The entire plant or flower is used for whooping cough.

The flowers are aperient, bitter, hypotensive, stomachic and vasodilatory. The flowers of *C. indicum* and *C. morifolium* (Kangiku) are listed in Japanese pharmacopeia as treatments of cephalalgia, vertigo and eye inflammation. The flowers of *C. indicum* is prescribed for anti-inflammatory, hypertension, analgesic and antipyretic purposes and the treatment of eye disease in Chinese traditional preparations. In Vietnam, the flowers are employed to treat cold, fever, photopsia, vertigo, headache, ophthalmia, dacryolithiasis, xerophthalmia, amblyopia, hypertension, boils, furunculus and phlegmon. Long-term use

is beneficial for qi and blood and rejuvenating. Flowers are externally applied as lotion or poultice to cure furunculosis. The flowers are used in the treatment of furuncle; scrofula; deep-rooted boils; mammary carbuncles; inflammation of the throat, eyes and cervix; eczema; and itchiness of the skin. The flowers are used as general tonic and to alleviate cough as well as externally to reduce bruising by the Hmong group of Vietnam. Emulsion of flowers is used for infections of the cervix; infusion of the flowering heads is used as carminative, and flowers are also burnt as insect repellent. In India, the flowers are employed as a stomachic and laxative. In Malaya, the flowers are used for sore eyes. In Guam, infusion of flowers is used as remedy for intermittent fevers and also used by women as remedy for hysteria and menstrual problems.

The leaves are depurative and used for migraine in Indochina and China.

Other Uses

Indian chrysanthemum is also widely cultivated as an ornamental. In China, it is used as a source of oil and source of nectar for bees.

Comments

Chrysanthemum indicum is one of the main parents of the florists' chrysanthemum (*Chrysanthemum morifolium*).

Almeida, *Cosmos aurantiacus* Klatt, *Cosmos sulphureus* var. *exaristatus*, *Cosmos sulphureus* var. *hirsuticaulis* Sherff.

Family

Asteraceae

Common/English Names

Klondike Cosmos, Orange Cosmos, Sulfur Cosmos, Yellow Cosmos

Vernacular Names

Chinese: Liu Huang Ju

French: Cosmos Soufré

German: Gelbe Kosmee, Gelbes Schmuckkörbchen, Schwefelgelbes

Indonesia: Kembang Goyang, Randa Meedang (Sundanese)

Japanese: Kibana Kosumosu

Mexico: Xochipelli

Philippines: Cosmos (Tagalog)

Portuguese: Cosmos Amarelo

Russian: Kosmos Tscheltys, Kosmos Želtyj

Spanish: Tostón

Swedish: Gullskära

Thai: Dawkajay

Vietnamese: Chuồn Chuồn Hoa Vang, Hoa Chuồn Chuồn

Origin/Distribution

The species is indigenous to Mexico in Central America. The plant has been introduced elsewhere around the world and is cultivated in India, Cambodia and Indonesia.

Agroecology

The plant thrives in average, medium moisture, moderately fertile, well-drained soils in full sun and tolerates fairly dry soil. Rich fertile soils tend to produce unusually tall, lanky plants that flop over. The plant is not frost hardy.

Edible Plant Parts and Uses

The young shoots and leaves are eaten as vegetables raw or cooked as 'lalab' or 'gudang' (side dish) with rice in Indonesia (Ochse and Bakhuizen van den Brink 1980). The flowers are edible and use in salads in Thailand (Kaisoon et al. 2011, 2012).

Botany

Annual robust, erect herbaceous plant, 30–200 (–100) cm high with terete, slightly compressed, sparsely pubescent to glabrescent and green stem. Leaves opposite, sessile or shortly petiolate, outline broadly ovate-rhomboid, 2–4 pinnately dissected with ultimate segments narrowly linear-lanceolate, 2.5 mm wide, apiculate and glabrous (Plates 1 and 2). Inflorescence terminal or axillary, solitary, 1.5 cm across, peduncle 1–2 cm long, outer involucre bracts narrowly ovate, acuminate, inner involucre bracts with membranous margins. Ray florets obovate, intensely yellow to deep orange, apex denticulate (Plates 1 and 2). Disc florets with narrowly funnel-shaped corolla, yellow, orange-yellow, 6–7 mm. Fruit a 2 cm achene, hispid, blackish, spindle-shaped pappus absent or of 2–3 widely divergent awns.

Nutritive/Medicinal Properties

The anthochlor pigment, named coreopsin, a glycoside of butein, was isolated from the ray florets (Geissman 1942). From the ray florets an anthochlor glycoside, sulphurein, was isolated

Plate 1 Yellowed flowers and leaves

Plate 2 Orange flowers and leaves

and its structure established as the 6-glucoside of sulphuretin (3',4',6-trihydroxybenzalcurmaranone) (Shimokoriyama and Hattori 1953). Also isolated from *C. sulphureus* was coreopsin, a glucoside of butein (3,4,2',4'-tetrahydroxychalcone). The structure of coreopsin was determined to be the 4'-glucoside of butein. *Cosmos sulphureus* flowers were found to contain 2'-hydroxy-4,4'-dimethoxychalcone and the leaves quercetin and stigmasterol-3-*O*- β -D-glucopyranoside (Huỳnh et al. 2005). A chalcone 3-hydroxylase (CH3H) cDNA clone was isolated and characterized from *Cosmos sulphureus* petals accumulating butein (2',3,4,4'-tetrahydroxychalcone) derivatives as yellow flower pigments (Schlangen et al. 2010).

Phenolic acids were detected in the ethanol extract of *Cosmos sulphureus* flowers (mg/100 g DW): gallic acid 9.25 mg, protocatechuic acid 3.26 mg, *p*-hydroxybenzoic acid 2.74 mg,

chlorogenic acid 6.90 mg, vanillic acid not detected, caffeic acid 13.88 mg, syringic acid 2.91 mg, *p*-coumaric acid 137 mg, ferulic acid 27.85 mg, and sinapic acid 5.88 mg and total 210.27 mg (Kaisoon et al. 2012). Flavonoid compounds found in the lyophilized hydrophilic extracts of *C. sulphureus* flowers (mg/100 g DW): rutin 19.67 mg, myricetin 59.99 mg, quercetin 9.45 mg, apigenin 7 mg, and kaempferol 25.6 mg and total 121.71 mg.

Antioxidant Activity

Soluble phenolic acid content ($\mu\text{g/g}$ DW) of the flowers comprised gallic acid 30 μg , protocatechuic acid 2.2 μg , *p*-hydroxybenzoic acid 10.2 μg , vanillic acid 9.3 μg , chlorogenic acid 72.8 μg , caffeic acid 13.47 μg , syringic acid 81 μg , *p*-coumaric acid 11.6 μg , ferulic acid 76.3 μg , sinapic acid 308.2 μg , and total phenolic acids 615.1 μg (Kaisoon et al. 2011). Bound phenolic acids contents ($\mu\text{g g/g}$): protocatechuic acid 21.8 μg , syringic acid 5.5 μg , *p*-coumaric acid 54.7 μg , ferulic acid 132.1 μg , sinapic acid 418.5 μg . Soluble flavonoid contents ($\mu\text{g/g}$ DW): rutin 7 μg , myricetin 4.9 μg , quercetin 485.9 μg , apigenin 0.72 μg , kaempferol 3.54 μg , total 502.1 μg . Bound flavonoid contents ($\mu\text{g/g}$ DW): rutin 31.7 μg , myricetin 2.8 μg , quercetin 109.2 μg , apigenin 14.5 μg , total 158.1 μg . The DPPH radical scavenging activity (percentage inhibition) of soluble and bound phenolic fractions were 87.04 and 33.41 %, respectively. The ferric reducing ability power of soluble and bound phenolic fractions expressed as FRAP values ($\text{mmol FeSO}_4/100 \text{ g DW}$) were 53.86 and 21.2 mmol, respectively.

In a subsequent comparative study of four edible flowers, the phenolics (mg GAE (gallic acid equivalent)/g DW) of the flowers were determined as follows: *Tagetes erecta* (212.9) > *Antigonon leptopus* (177.2) > *Bougainvillea glabra* (138.2) > *Cosmos sulphureus* (102.5) (Kaisoon et al. 2012). Total reducing capacity (FRAP) ($\mu\text{mol Fe}^{2+}/\text{g DW}$) was ranked as *Tagetes erecta* (329.4) > *Bougainvillea glabra* (307.1) > *Antigonon*

leptopus (281.9) > *Cosmos sulphureus* (99.9). The ORAC (oxygen radical absorbance capacity) ($\mu\text{mol T Eq}$ (trolox equivalent)/g DW) ranks were *Antigonon leptopus* (491.9) > *Tagetes erecta* (394.2) > *Bougainvillea glabra* (276) > *Cosmos sulphureus* (214.8). Cellular antioxidant activity (CAA) ($\mu\text{M QE}$ (quercetin equivalent)/g DW) ranks were *Tagetes erecta* (413, most effective) > *Bougainvillea glabra* (859.6) > *Cosmos sulphureus* (966.1) > *Antigonon leptopus* (967.4).

Antidiabetic Activity

Inhibitory activity of lyophilized hydrophilic extracts obtained from four edible Thai flowers against α -glucosidase enzyme was found as *Tagetes erecta* (98.51 % inhibition, IC_{50} 0.06 mg/ml) > *Antigonon leptopus* (58.24 % inhibition, IC_{50} 3.26 mg/ml) > *Bougainvillea glabra* (37.30 % inhibition, IC_{50} 5.21 mg/ml) > *Cosmos sulphureus* (32.32 % inhibition, IC_{50} 5.62 mg/ml) (Kaisoon et al. 2012).

Hypolipidemic Activity

Inhibitory activity of lyophilized hydrophilic extracts obtained from four edible Thai flowers against lipase activity was determined as *Cosmos sulphureus* (43.39 % inhibition, IC_{50} 4.60 mg/ml) > *Tagetes erecta* (41.61 % inhibition, IC_{50} 4.82 mg/ml) > *Bougainvillea glabra* (40.05 % inhibition, IC_{50} 5.14 mg/ml) > *Antigonon leptopus* (26.70 % inhibition, IC_{50} 7.87 mg/ml) (Kaisoon et al. 2012).

Antiproliferative Activity

Cosmos sulphureus had lowest antiproliferative activity among four edible flowers tested (Kaisoon et al. 2012). Antiproliferative activity (IC_{50} mg/ml) of polyphenolic extract against HC-29 (colorectal adenocarcinoma) cells was *Tagetes erecta* > (1.5) > *Bougainvillea glabra* (1.7) > *Antigonon leptopus* (2.4) > *Cosmos*

sulphureus (5.2). Antiproliferative activity (IC_{50} mg/ml) of polyphenolic extract against AGS (gastric adenocarcinoma) cells was *Antigonon leptopus* (0.2) > *Bougainvillea glabra* (2.1) > *Tagetes erecta* (2.2) > *Cosmos sulphureus* (44.8). Antiproliferative activity (IC_{50} mg/ml) of polyphenolic extract against BI-13 (bladder cancer) cells was *Antigonon leptopus* (0.9) > *Bougainvillea glabra* (2.3) > *Tagetes erecta* (3.0) > *Cosmos sulphureus* (56.5).

Antimalarial Activity

In Brazil, the plant is traditionally used for malaria; an ethnobotanical study showed *Cosmos sulphureus* to have activity against *Plasmodium* (Botsaris 2007).

Traditional Medicinal Uses

The leaves are used in native medicine in Indonesia (Ochse and Bakhuizen van den Brink 1980) and in Brazil for malaria (Botsaris 2007).

Other Uses

A popular ornamental plant in cottage gardens and public places, commonly seen in mass planting along roadsides, beds and borders in Korea and Japan.

The flower heads of *Cosmos sulphureus* and other *Cosmos*, *Bidens* and *Coreopsis* species have provided important sources of yellow to orange dyes among the pre-Columbian civilizations of Central and South America (Jansen 2005). In southern Africa, they were adopted as a popular yellow dye by European settlers for domestic textile production and are still used by dyers using natural dyes as a hobby or for textile crafts, to dye wool bright yellow or orange. Wool dyed with *Cosmos* flower dye exhibit excellent to outstanding sunlight fastness irrespective of mordant combination and mordanting method (Kale et al. 2005).

Comments

The flowers of all *Cosmos* including this species attract birds and butterflies.

Origin/Distribution

Cynara cardunculus is native to the Mediterranean and Macaronesia. Cladistic studies based on morphological character of a large set of specimens by Wiklund (1992) confirmed the inclusion of cultivated artichoke, leafy cardoon and wild cardoon in a single species: *Cynara cardunculus* L. The wild perennial taxon, *Cynara cardunculus* var. *sylvestris* (Lamk) Fiori, has been recognized as the ancestor of both the globe artichoke [var. *sativa* Moris, var. *scolymus* (L.) Fiori, ssp. *scolymus* (L.) Hegi] and the leafy or cultivated cardoon (var. *altilis* DC) (Rottenberg and Zohary 1996). Recent studies on isozymes and molecular markers such as RAPDs and AFLPs (Rottenberg et al. 1996; Sonnante et al. 2002, 2004; Raccuia et al. 2004a) have confirmed that both crops evolved from the wild cardoon gene pool, which can therefore be considered the progenitor of both of them. *Cynara cardunculus* has been divided into two subspecies: the western morph is subsp. *flavescens* mainly found in Macaronesia, Portugal and the northwest Mediterranean region; the eastern morph is subsp. *cardunculus* found mainly in central to northeast Mediterranean region (Wiklund 1992). The subspecies differ mainly by a yellowish margin on the middle involucral bract (Wiklund 1992). There are also a number of varieties of *C. cardunculus* including the cultivated artichoke var. *scolymus* (L.) Fiori, the wild artichoke var. *sylvestris* (Lam.) Fiori, and the leafy cardoon var. *altilis* DC (Pignone and Sonnante 2004).

Globe artichoke is widely cultivated in the Mediterranean area, chiefly in Spain, Italy and France, also in the southern United States, South America, China, Egypt, Morocco, and elsewhere

including Vietnam, in the Dalat Highlands where it is grown mainly for producing artichoke tea and also as vegetables. In the United States, California provides more than 90 % of the US Crop.

Agroecology

Globe artichoke is a cool-season crop (Basnizki 1985; Bianco 1990; Bratsch 2009), with a wide adaptive range of 7–30 °C. It grows best in areas with day temperatures of 20–22 °C and 12–14 °C in the night, representing the optimal values to obtain compact and tender heads for an extended period. The minimal biological temperature ranges between 7 and 9 °C, while the lethal one is lesser than –10 °C (Bianco 1990). Frosts damage outer portions of the buds; severe or frequent frosts damage or kill the plants. Plants are tolerant to high temperatures (>30 °C) that, however, tend to decrease the quality of edible heads. Perennial plantings are not recommended in areas where warm to hot temperatures are common. In areas with hot, dry summers, shading and mist irrigation may help vegetative growth, but hot growing conditions tend to toughen bud scales, reduce palatability and produce poor yields. New artichoke plants require ‘vernalization’ or ‘chilling’ (Bratsch 2009). This occurs just after planting, with seedling exposure to cool temperatures (8–10 days or of 7–10 °C). Globe artichokes are obligated long-day plants with a critical photoperiod of 10.5 hours. In seed-planted individuals, the transition from vegetative to reproductive stage depends on the interaction between the following factors (Basnizki 1985): attainment of a critical plant size (usually a rosette of seven to eight leaves), low temperatures and photoperiod. The globe artichoke are deep-rooted crops; it can be grown on a wide range of soils, but it produces best on deep, fertile, friable, well-drained soils with a pH between 6 and 8. The extremes of heavy clay and light sandy soils should be avoided (Bratsch 2009). It abhors water-logged condition and raised-bed culture is recommended where drainage is suspect.

Edible Plant Parts and Uses

The edible portion of the immature flower head (capitulum) consists primarily of the fleshy lower portions of the involucre bracts (phyllaries) and the fleshy base of the receptacle (Plates 1 and 2), known as the ‘heart’; the mass of inedible immature florets in the centre of the bud are called the ‘choke’. The lower fleshy parts of the involucre bracts (phyllaries) and the fleshy receptacle are eaten raw boiled, steamed, baked, fried, stuffed, marinated, pickled, made into artichoke dips or mixed into yoghurt (Grieve 1971; Facciola 1990; Roberts 2000; Anonymous 2013). The young blanched chards (tender leaf stalks) are also eaten and deemed by some to equal that of cardoon chards (Grieve 1971). The bracts are removed after cooking and eaten one at a time, sometimes dipped in butter, hollandaise, mayonnaise, aioli,

Plate 1 Plant habit of globe artichoke

Plate 2 Harvest globe artichokes

Plate 3 Harvested globe artichoke and leaves for sale

Plate 4 Artichoke leaves and petioles sold as vegetables

lemon juice or other sauces. The chards and flowering stems are eaten cooked—blanched, braised or fried, and added to sauces. The bitter young leaves are also eaten cooked (Plates 3 and 4). In France, artichoke receptacles are very popular deep fried or made into artichoke ragout (*'artichauts en ragoût'*); the dried receptacles are used in soups. In Italy, artichoke hearts in oil are the usual vegetable for spring in the 'Four Seasons' pizza; whole artichoke can be deep fried as in the popular recipe Jewish-style artichokes or used in Italian stuffed artichokes with a stuffing mixture of bread crumbs, garlic, oregano, parsley, grated cheese and prosciutto or sausage. In Greece, a savoury and wholesome stew, *'aginaires a la polita'*, is prepared with artichoke hearts, potatoes and carrots, and flavoured with onion, lemon and dill. In Spain, the more tender, younger and smaller artichokes are sprinkled with olive oil and barbecued or sautéed in olive oil with garlic, with rice as a paella, or sautéed and combined with eggs in a tortilla (frittata).

Plate 5 Artichoke flower-head shavings used for tea

Ground lamb with different spices, raisins, pine nuts and herbs are used as stuffing in artichoke hearts in Turkey, Armenia and throughout North Africa and the Middle East.

The dried flowers are used as rennet substitute for curdling/coagulating milk.

Leaves are often removed and eaten one at a time, sometimes dipped in butter, mayonnaise, aioli or other sauces. Artichokes can also be made into an herbal tea; artichoke tea is produced as a commercial product in the Dalat region of Vietnam (Plate 5). In Mexico, the flower portion is put into water and consumed as a tisane called *'alcachofa'*. Artichoke is the primary flavour of the Italian liquor Cynar. It can be served over ice as an aperitif or as a cocktail mixed with orange juice, which is especially popular in Switzerland.

Recent studies found that the incorporation of artichoke leaf and stem meal, as a source of fibre, modified significantly wheat bread textural properties for the formulations of 9 and 12 % (Frutos et al. 2008). Breads with artichoke fibre presented higher fibre content and were considered acceptable by the sensory panel, indicating this ingredient to be adequate for its use as a fibre source in wheat bread.

The blanched leaf stalks of cardoon are eaten boiled, batter fried, sautéed, braised and pickled, or used in stews and soups (Facciola 1990; Hedrick 1972). In Italy, raw strips are dipped in olive oil or *bagna cauda*, a hot, anchovy and garlic dip. The tender, fleshy root can be cooked like carrot or parsnip and has an agreeable flavour. Flower-head receptacle is eaten like for artichoke.

Flowers of *Cynara cardunculus* (cardoon) have been traditionally used as coagulants in Portugal and Spain for many centuries to produce traditional artisanal cheeses (Cordeiro et al. 1998; Sidrach et al. 2005). Aspartic proteinases from flowers of *Cynara cardunculus* have been extensively studied and long used as coagulants in the manufacture of several traditional Spanish and Portuguese cheeses (Sidrach et al. 2005). Today, the Serpa and Serra cheeses are some examples of typical and highly appreciated products of Portugal.

Botany

An erect, spiny, biennial or perennial herb growing to 1–2 m high by 1 m wide (Plate 1) with a fleshy taproot. Young growth is arachnoid tomentose and stems short and striate ribbed. Leaves (Plates 1, 3, 4, and 6) are rosulate on young plants; alternate on stems and on short, rigid petioles; ovate to lanceolate in outline; large, 30–50 cm long by 10–20 cm wide; pinnatifid or parted; silvery glaucous-green; pubescent to glabrescent above greyish-tomentose below; segments lanceolate and spiny; caudate; base sessile; and decurrent into wings on the stem (Plates 1 and 6). Flower purple-blue; all discoid in a loose, large (6–10 cm across the base) ovate capitula (involucre) (Plates 2, 3 and 4); and terminal on a long flowering stem to 1.5 m (Plates 6 and 7). Phyllaries broadly ovate, bases adpressed, spiny apex, green or tinged with purple or wholly purple, base fleshy, 1–5 cm long by 1–2 cm across the base, receptacle flat, and 2–2.5 cm diameter surrounding numerous tubular florets. Corollas blue or purple, 3–5 cm long, membranous, apical appendages rounded, style exerted. Achene, oblong, 4 angled, shiny brown, with plumose, white pappus, and 2–2.5 cm long.

Nutritive/Medicinal Properties

Globe artichoke is largely cultivated for its fleshy head or capitula (immature inflorescence) which accounts for 30–40 % of the fresh weight (Christakia et al. 2012). The edible portion of the

Plate 6 Artichoke plant with unopened flower head

Plate 7 Close view of fully opened mature flower head

head comprised the tender inner bracts and the receptacle commonly referred to as the ‘heart’, accounting for 33–55 % of the head (Ceccarelli et al. 2010). Analyses carried out in the United States (USDA 2012) reported raw, globe artichoke head to have the following proximate composition (per 100 g edible portion): water 84.94 g, energy 47 kcal (197 kJ), protein 3.27 g, total lipid 0.15 g, ash 1.13 g, carbohydrates 10.51 g, total dietary fibre 5.4 g, total sugars 0.99 g, Ca 44 mg, Fe 1.28 mg, Mg 60 mg, P 90 mg, K 370 mg, Na 94 mg, Zn 0.49 mg, Cu 0.231 mg, Mn 0.256 mg, Se 0.2 µg, vitamin C 11.7 mg, thiamine 0.072 mg, riboflavin 0.066 mg, niacin 1.046 mg, pantothenic acid 0.338 mg, vitamin B-6 0.116 mg, total folate 68 µg, choline 34.4 mg, betaine 0.2 mg, vitamin A 13 IU, vitamin E (α-tocopherol) 0.19 mg, vitamin K (phylloquinone) 14.8 µg, total saturated fatty acids 0.036 g, 12:0 (lauric acid) 0.002 g, 14:0 (myristic acid) 0.002 g, 16:0 (palmitic acid) 0.029 g, 18:0 (stearic acid) 0.003 g,

total monounsaturated fatty acids 0.005 g, 18:1 undifferentiated 0.005 g, total polyunsaturated fatty acids 0.064 g, 18:2 undifferentiated 0.046 g, 18:3 undifferentiated 0.017 g, β -carotene 8 μ g and lutein + zeaxanthin 464 μ g.

Analyses carried out in the United States (USDA 2012) reported raw, cardoon to have the following proximate composition (per 100 g edible portion): water 94.00 g, energy 17 kcal, protein 0.7 g, total lipid 0.10 g, ash 1.13 g, carbohydrates 4.07 g, total dietary fibre 1.6 g, Ca 70 mg, Fe 0.708 mg, Mg 420 g, P 23 mg, K 400 mg, Na 170 mg, Zn 0.17 mg, vitamin C 2.0 mg, thiamine 0.020 mg, riboflavin 0.06630 mg, niacin 0.30 mg, vitamin B-6 0.116 mg, folate DFE 68 μ g, total saturated fatty acids 0.011 g, total monounsaturated fatty acids 0.018 g and total polyunsaturated fatty acids 0.041 g.

Data obtained suggested that the edible parts (receptacles with inner and intermediate bracts) of flower heads of artichoke cultivars could represent a good source of health-promoting polyphenols (chlorogenic acid, coumaric acid, ferulic acid, cynarin, luteolin, apigenin) and therefore should be encouraged as a nutraceutical use, as an alternative to the more traditional phytopharmaceutical applications of leaf extracts of the species (Fratianni et al. 2007). Moreover, it was demonstrated that single polyphenols accumulate preferentially in specific parts of the heads and in specific genotypes.

Phenolic acids (caffeoylquinic acids) and flavonoids (luteolin and apigenin derivatives) were found in the immature inflorescence of globe artichoke, wild cardoon and cultivated cardoon (Pandino et al. 2010). Apigenin derivatives represented the major class in all samples investigated and highest in cardoon forms. Caffeoylquinic acids and luteolin derivatives were observed in globe artichoke only. The outer bracts of the flower head were found to have very low phenolic content (443 mg/kg dry matter (dm)) or zero hydroxycinnamic acid content; in contrast the receptacle (edible part) contained the highest amount, 1,473 mg/kg dm, and the inner bracts contained slightly lower, intermediate content (Pandino et al. 2011b). Globe artichoke

is an ancient herbaceous plant native to the Mediterranean Basin. The edible part (flower head) of globe artichoke was found to be particularly rich in polyphenols; 19 phenolic compounds were determined (Lombardo et al. 2010) as follows: 1-*O*-caffeoylquinic acid; 3-*O*-caffeoylquinic acid; 5-*O*-caffeoylquinic acid (or chlorogenic acid); 4-*O*-caffeoylquinic acid; caffeic acid; 1,3-di-*O*-caffeoylquinic acid (or cynarin); luteolin 7-*O*-rutinoside; luteolin 7-*O*-glucoside; luteolin 7-*O*-glucuronide; narirutin; naringenin 7-*O*-glucoside; di-caffeoylquinic acid; 3,4-di-*O*-caffeoylquinic acid; 3,5-di-*O*-caffeoylquinic acid; 1,5-di-*O*-caffeoylquinic acid; apigenin 7-*O*-rutinoside; apigenin 7-*O*-glucoside; apigenin 7-*O*-glucuronide; and 4,5-di-*O*-caffeoylquinic acid. Apigenin 7-*O*-glucuronide was found to be the major flavonoid, with 6,298 mg/kg DM in 'Romanesco clone C3' receptacle, whereas chlorogenic acid represented the main caffeoylquinic acid, reaching 14,841 mg/kg DM in the inner bracts of 'Violetto di Sicilia'.

In fresh marketable artichoke flower heads, only traces of free apigenin and luteolin were identified, while in badly injured heads, measurable amounts of the above flavonoids, as well as of free caffeic acid, were found to occur (Lattanzio and Van Sumere 1987). Also present are vanillic-, syringic-, *p*-coumaric- and ferulic acids, although caffeic acid proved to be the main phenolic component. Additionally, the latter phenolic acid increased considerably during storage of the healthy heads for 2 weeks at 20 °C or for 1 month at 4 °C, the increase at 20 °C being the most pronounced. In injured heads (internal blackening) stored for 2 weeks at 20 °C, a decrease in caffeic acid, as well as in most other phenolics, was recorded, while in badly injured heads, stored for the same period of time, less than half of the total amount of the caffeic acid present in fresh marketable heads was found. However, in injured heads stored for 1 month at 4 °C, the decrease in caffeic acid proceeded less rapidly. The main phenolic compounds in dried artichoke extracts were mono-caffeoylquinic acids (0.48–4.24 %), the most abundant, dicaffeoylquinic acid, and flavonoid contents were smaller, from 0.03 to 0.52 % (Häusler et al. 2002). The compound

identified included pseudochlorogenic acid; neochlorogenic acid; chlorogenic acid; cryptochlorogenic acid; cynarin; 3,4-di-*O*-caffeoylquinic acid; 1,5-di-*O*-caffeoylquinic acid, 3,5-di-*O*-caffeoylquinic acid; 4,5-di-*O*-caffeoylquinic acid; and cynaroside scolymoside and cynaropikrin. Three di-*O*-caffeoylquinic acid derivatives were isolated from the ethanol extracts of the flower heads of *Cynara scolymus* (Zhu et al. 2009).

Among the 22 major phenolic compounds from artichoke (*Cynara scolymus*) heads, juice and pomace, 11 caffeoylquinic acids and 8 flavonoids were detected (Schütz et al. 2004). Apigenin 7-*O*-glucuronide was found to be the major flavonoid in all samples investigated. 1,5-di-*O*-caffeoylquinic acid represented the major hydroxycinnamic acid, with 3,890 mg/kg in artichoke heads and 3,269 mg/kg in the pomace, whereas in the juice 1,3-di-*O*-caffeoylquinic acid (cynarin) was predominant, due to the isomerization during processing. Total phenolic contents of approximately 12 g/kg on a dry matter basis revealed artichoke pomace to be a promising source of phenolic compounds that might be recovered and used as natural antioxidants or functional food ingredients. Chlorogenic acid represented the major constituent in all artichoke-based dietary supplements investigated with the exception of juice derived from fresh flower heads, which exhibited a higher cynarin content (Schütz et al. 2006a). Furthermore, a distinction between products made from artichoke leaves or flower heads was possible. Caffeoylquinic acid derivatives, including chlorogenic acid, 1,3-di-*O*-caffeoylquinic acid (cynarin) and 1,5-di-*O*-caffeoylquinic acid in artichoke heads and leaves were analyzed and quantified by ultrafast liquid chromatography/tandem mass spectrometry (Shen et al. 2010). Average recoveries ranged from 92.1 to 113.2 %. Seven active polyphenolic compounds including apigenin-7-rutinoside and narirutin were purified from artichoke heads and leaves (Wang et al. 2003).

Both artichoke flower heads and leaves were found to be rich in phenolic compounds: benzoic and cinnamic derivatives, flavonoids and tannins (Lattanzio et al. 2005, 2009). The phenolic

aglycons identified as soluble-bound or insoluble bound phenolics were caffeic, *p*-coumaric, ferulic, vanillic and syringic acids, and the flavonoids apigenin and luteolin. In addition, tannins (most abundant), hydrolyzable and condensed tannins or proanthocyanidins were also identified. The content of all identified phenolics decreased with the stages of development of plant tissues. Nevertheless, a high total phenolic content was found in artichoke by-products (about 2–3 % on dry matter basis). The cinnamoyl derivatives comprised four mono-caffeoylquinic acids (1-*O*-caffeoylquinic acid, 3-*O*-caffeoylquinic or neochlorogenic acid, 4-*O*-caffeoylquinic or cryptochlorogenic, and 5-*O*-caffeoylquinic or chlorogenic acid, the most abundant) and six di-caffeoylquinic acids (1,3-*O*-dicafeoylquinic acid or cynarin; 1,4-*O*-dicafeoylquinic acid; 1,5-*O*-dicafeoylquinic acid; 3,4-*O*-dicafeoylquinic acid; 3,5-*O*-dicafeoylquinic acid; and 4,5-*O*-dicafeoylquinic acid). The cynarin content was very low, while 3,5-*O*-dicafeoylquinic acid and 1,5-*O*-dicafeoylquinic acid were the most abundant components. Also, two flavonoids, apigenin-7-glycoside and luteolin-7-glycoside, were detected. The nomenclature of the mono-caffeoylquinic and dicafeoylquinic acids is in accordance with the nomenclatural rules of IUPAC (1976).

Cyanidin 3,5-diglucoside; cyanidin 3-caffeoylsophoroside-5-glucoside; cyanidin 3-sophoroside; cyanidin 3-glucoside; cyanidin 3-caffeoylsophoroside; and cyanidin 3-caffeoylglucoside were identified in artichoke flowers, bracts and leaves (Aubert and Foury 1981). Besides the main anthocyanins found in artichoke heads (cyanidin 3,5-diglucoside; cyanidin 3-glucoside; cyanidin 3,5-malonyldiglucoside; cyanidin 3-(3''-malonyl)glucoside; and cyanidin 3-(6''-malonyl)glucoside), several minor compounds, namely, cyanidin 3-sophoroside; cyanidin malonylglucoside; cyanidin malonyldiglucoside; delphinidin glycoside; cyanidin malonylsophoroside; cyanidin pentoside; cyanidin 3-(6''-malonyl)glucoside; peonidin 3-*O*- β -glucoside; and peonidin 3-(6''-malonyl)glycoside were identified (Schütz et al. 2006c). Total anthocyanin content ranged from 8.4 to 1,705.4 mg/kg dry mass.

Of 32 aroma components of the volatile oil of cooked artichoke, the major components were the sesquiterpenes β -selinene and caryophyllene (Buttery et al. 1978). Components deemed most important to the aroma included oct-1-en-3-one, hex-1-en-3-one, decanal, non-*trans*-2-enal, phenylacetaldehyde and eugenol. All the components identified included aliphatic alcohols (2-methylbutanol and 3-methylbutanol (0.9 %), 3-methylbut-2-en-1-ol (2.2 %), hex-*cis*-3-enol (3.5 %), hex-*trans*-2-enol (1.3 %), hexanol (2.7 %), and methyl heptanol (tentative) (2.5 %)), aliphatic aldehydes (non-*trans*-2-enal (0.2 %), pentanal (0.2 %), decanal (0.4 %), hexanal (0.5 %), octanal (0.2 %), nonanal (0.6 %), heptanal (0.2 %), and hex-*trans*-2-enal (1.6 %)), aliphatic ketones (oct-1-en-3-one (0.6 %), hex-1-en-3-one (0.8 %), pentan-2-one (0.1 %), and butan-2,3-dione (90.1 %)), aromatic and heterocyclic compounds (phenylacetaldehyde (7 %), eugenol (2–5 %), pyridine (0.2 %), 2-petnylfuran (0.9 %), furfural (2 %), 2-acetylthiazole (0.1 %), benzaldehyde (0.8 %), benzyl alcohol (1 %), eugenol), terpene alcohols (linalool (0.4 %), α -terpineol (0.2 %), and linalool oxide C (5-hydroxy-2,6,6-trimethyl-2-vinyltetrahydropyran) (0.5 %), and sesquiterpenes hydrocarbons (β -selinene (40 %), caryophyllene (19 %) and humulene (1 %)).

The edible part of artichoke heads was reported to contain a high reducing sugar content and a high percentage of water-soluble polysaccharides (inulin), mainly concentrated in the receptacle; the inulin content may constitute 75 % of the total glucidic content (Lattanzio et al. 2009). Lattanzio et al. (2009) adapting from earlier work (Lattanzio et al. 2002) reported that the glucidic content of the edible portion of artichoke head of cv. Romanesco per fresh weight and dry weight basis were respectively as follows: glucose 0.44 %, 3.18 %; fructose 0.18 %, 1.27 %; sucrose 0.98 %, 6.98 %; and inulin 5.18 %, 37 %. In another study, glucose, fructose, sucrose and individual fructooligosaccharides (kestose, nystose, fructofuranosylnystose) were quantified in the heads of six different artichoke cultivars (Schütz et al. 2006b). The contents ranged from 12.9 to 71.7 g/kg DM for glucose, from 15.8 to

67.2 g/kg DM for fructose, and from 16.8 to 55.2 g/kg DM for sucrose in the artichoke heads. Kestose was the predominant fructooligosaccharide, followed by nystose and fructofuranosylnystose. In four cultivars fructofuranosylnystose was only detectable in traces and reached its maximum value of 3.6 g/kg DM in the cultivar Le Castel.

Two taraxastane-type hydroxy triterpenes, taraxasterol and faradiol, were isolated from the flowers (Yasukawa et al. 1996). A recombinant cyprosin, an aspartic proteinase from cardoon (*Cynara cardunculus*) flowers, was purified and characterized (White et al. 1999). It was found to consist of glycosylated heavy chains (34 or 32 kDa) plus associated light chains with molecular weights in the region of 14,000–18,000. It was also found to be susceptible to inhibitors of human immunodeficiency virus proteinase and particularly of rennin. Polyphenol oxidase (PPO) was purified from hearts of artichoke (Leoni et al. 1990). The best substrates for the enzyme at pH 6.0 were 5-*O*-caffeoylquinic acid (relative activity 100 %) and caffeic acid (relative activity 69 %). Although both ascorbic and citric acids were known to considerably improve the shelf life of artichoke heads, only ascorbic acid proved to be significantly inhibitory towards artichoke polyphenol oxidase. Polyphenol oxidase isolated from artichoke heads exhibited both monophenolase and diphenolase activities (Espin et al. 1997). Monophenolase activity of artichoke PPO was characterized using 4-hydroxyanisole as substrate with 3-methyl-2-benzothiazolinone hydrazone as a coupled nucleophile. The PPO isolated from artichoke head had a 57 kDa molecular mass (Dogan et al. 2005). The enzyme showed activity to 4-methylcatechol, pyrogallol, catechol and L-dopa but not to L-tyrosine, resorsinol and *p*-cresol. The optimum pH values for PPO were 5.0, 8.0 and 7.0 using 4-methylcatechol, pyrogallol and catechol as substrate, respectively. A basic heme peroxidase isoenzyme (AKPC) was purified from artichoke flowers (López-Molina et al. 2003). The enzyme was shown to be a monomeric glycoprotein, $M_r=42,300$. The substrate specificity of AKPC was characteristic of class III (guaiacol-type) peroxidases with

chlorogenic and caffeic acids that are abundant in artichoke flowers, as particularly good substrates at pH 4.5. AKPC, when purified, were found to be a mixture of Ca^{2+} -bound pentacoordinate high-spin (5cHS) and 6-aquo hexacoordinate high-spin (6cHS) ferric heme, and Ca^{2+} -free 5cHS species (Hiner et al. 2003).

Leaf/Aerial Parts Phytochemicals

The amino acid composition of the leaves (g/kg) was determined as aspartic acid 5.21 g, threonine 6.14 g, serine 5.96 g, glutamic acid 9.51 g, glycine 4.17 g, alanine 5.50 g, valine 6.57 g, methionine 10.15 g, isoleucine 4.88 g, leucine 7.71 g, leucine 7.71 g, tyrosine 3.44 g, phenylalanine 6.32 g, histidine 3.19 g, lysine 7.18 g, arginine 4.99 g and total amino acids 80.84 g (Orlovskaya et al. 2007b). They also determined the mineral composition of the leaves (mg %), Na (2070), K (690), Ca (690), Mg (207) and P (207), and 16 were microelements Cu (0.345), Zn (0.414), Ag (0.0007), Mo (0.035), Li (0.207), Pb (0.069), Co (0.007), Ni (0.021), Ti (1.380), V (0.021), Cr (0.041), Fe (20.7), B (2.07), Al (13.8), Si (34.5) and Mn (2.07). The leaves and ethanol leaf extract also contained the following flavonoids (% of total phenolic compounds) (Orlovskaya et al. 2007b): luteolin-7-glucoside 35.19 %, 6.03 %; rutin 0.08 %, 6.33 %; dihydroquercetin 0.91 %, 0; vitexin 5.31 %, 0; orientin 0.46 %, 0; hyperoside 0.01 %, 7.47 %; apigenin 0, 0.89 %; hesperidin 2.33 %, 0; robinin 0, 1.27 %, respectively. The leaves and ethanol leaf extract also contained the following (% of total phenolic compounds): coumarin-4-hydroxycoumarin 0.88 %, 0; phenolic acids—gallic acid 0, 23.48 %; cichoric acid 0, 5.86 %; hydroxycinnamic acids—chlorogenic acid 0.10 %, 23.79 %; neochlorogenic acid 6.88 %, 2.38 %; caffeic acid 38.55 %, 6.30 %; ferulic acid 0, 5.54 %; phenolic glycoside—arbutin 9.31 %, 0, respectively.

From artichoke leaves the following compounds were isolated: flavonoids (apigenin, luteolin, luteolin-4'-glucoside, cynaroside, scolimoside, cosmoside, quercetin, rutin, isorhamnetin

and luteolin-7-gentiobioside) (El-Negoumy et al. 1987; Hinou et al. 1989) and phenolic acids (cynarin, chlorogenic acid, caffeic acid, neochlorogenic acid, quinic acid, 4-caFFEYLquinic acid, 1-caFFEYLquinic acid (Drarik 1966), and isochlorogenic acid), along with the more uncommon scopoletin, hesperitin, hesperidoside, esculetin-6-*O*- β -glucoside and maritimin (Hinou et al. 1989). Glycosyl flavonoids (cynaroside and scolimoside) were found to be the major constituents, along with cynaropicrin, a sesquiterpene lactone, and the triterpene lupeol and chlorogenic acid in artichoke leaves (Noldin et al. 2003). Cynarin, the main compound described for artichoke, was detected in very low concentration. From the dried leaf powder, the following flavonoids were isolated: luteolin-7-*O*- α -L-rhamnosyl(1 \rightarrow 6)- β -D-glucopyranoside, luteolin-7-*O*- β -D-glucopyranoside (cynaroside), apigenin-7-*O*- α -L-rhamnosyl(1 \rightarrow 6)- β -D-glucopyranoside (apigenin-7-rutinoside) and apigenin-7-*O*- β -D-glucopyranoside (Zhu and Zhang 2004). Eight phenolic compounds were isolated from the *n*-butanol-soluble fraction of artichoke leaf extract: four caFFEYLquinic acid derivatives, chlorogenic acid (1), cynarin (2), 3,5-di-*O*-caFFEYLquinic acid (3) and 4,5-di-*O*-caFFEYLquinic acid (4), and the four flavonoids, luteolin-7-rutinoside (5), cynaroside (6), apigenin-7-rutinoside (7) and apigenin-7-*O*- β -D-glucopyranoside (8) (Zhu et al. 2004). The main polyphenols detected in different tissues and developmental stages of 6 artichoke varietal types were chlorogenic acid, cynarin, luteolin 7-*O*-rutinoside and luteolin 7-*O*-glucoside (Negro et al. 2012). 'Violet de Provence' artichoke proved to retain the highest content of total phenols. Single polyphenols accumulated preferentially in specific parts of capitula. In leaves, most polyphenols were detected in the productive stage of the plant. Thirty-nine chlorogenic acids were detected in the leaves of 12 species of the Asteraceae family including *Cynara scolymus* (Jaiswal et al. 2011). Both chlorogenic acids based on *trans*- and *cis*-cinnamic acid substituents were identified. Assignment to the level of individual regioisomers was possible for seven caFFEYLquinic acids (1–7), 11 dicaFFEYLquinic acids (17–27), six

feruloylquinic acids (9–14), two *p*-coumaroylquinic acids (15–16), two caffeoyl-feruloylquinic acids (28 and 29), four caffeoyl-*p*-coumaroylquinic acids (30–33), three dicaffeoyl-succinoylquinic acids (34–36), two dicaffeoyl-methoxyoxaloylquinic acids (37 and 38) and one tricaffeoylquinic acid (39). In addition, one caffeoylshikimic acid (40), one caffeoyltartaric acid (41), three dicaffeoyltartaric acids (42–44) and three caffeoyl-feruloyltartaric acids (45–47) were detected.

The carbohydrates of the leaves comprised alcohol-soluble sugars 21.34 % with traces of glucose; cold water-soluble polysaccharides 5.1 % made up of rhamnose: xylose: arabinose: mannose: glucose: galactose in the ratio of 1.0:1.4:tr: 24.6:7.3; hot water-soluble polysaccharides 0.78 % made up of rhamnose: xylose: arabinose: mannose: glucose: galactose in the ratio of 1.62:3.2:2.2:1.0:tr:2.4; pectinic substances 2.4 % made up of rhamnose: xylose: arabinose: mannose: glucose: galactose in the ratio of 4.3:1.0:2.5:0:0:1.4; hemicelluloses 2.63 % made up of rhamnose: xylose: arabinose: mannose: glucose: galactose in the ratio of tr:8.76:4.6:1.4:1.0:4.8 (Orlovskaya et al. 2007a).

In the leaves of cultivated and wild *Cynara cardunculus*, the flavones were the major compounds, whereas in the floral stem, caffeoylquinic acids were the most abundant (Pandino et al. 2011a). In particular, ‘Sylvestris Creta’ (var. *sylvestris*, wild cardoon) and ‘Violetto di Sicilia’ (var. *scolymus*, globe artichoke) showed the highest content of caffeoylquinic acid ~95 % of the total measured polyphenols. The major compounds present in the leaf were luteolin derivatives in globe artichoke and apigenin derivatives in wild and cultivated cardoon.

From the cauline leaves of *C. scolymus*, cynarin, a substance with stimulatory action on biliary secretion and cholesterinic metabolism, was isolated (Panizzi and Scarpati 1954). From artichoke leaves the following flavonoids were isolated: luteolin 7- β -glycoside and luteolin 7- β -rutinoside (Dranik et al. 1964); a flavonoid glycoside, cynarotriside, having the structure luteolin 7-[*O*- β -D-glucopyranosyl-(6 \rightarrow 1)-*O*- β -L-rhamnopyranoside]-4'-*O*- β -D-glucopyranoside (Dranik and Chernobai 1966); luteolin,

cynaroside (luteolin-7-glucoside) and scolymoside (luteolin-7- β -rutinoside) (Constantinescu et al. 1967); and apigenin, luteolin, apigenin-7-*O*-glucoside, cynaroside (luteolin-7-glucoside) and scolymoside (luteolin-7- β -rutinoside) (Hammouda et al. 1993). From the leaves the following phenolic acids and flavonoids were detected: chlorogenic acid, 1,3-di-*O*-caffeoylquinic acid, cryptochlorogenic acid, neochlorogenic acid and 3,5-di-*O*-caffeoylquinic acid; flavonoids: luteolin-4'-*O*-glucoside, luteolin 7-*O*-glucoside and luteolin 7-*O*-rhamnoglucoside (Bombardelli et al. 1977). The following organic acids were detected in artichoke: glyceric, malic, citric, glycolic, lactic and succinic acids (Bogaert et al. 1972). Lattanzio and Morone (1979) found that chlorogenic acid content declined from 4.4 to 1.6 % dry matter (dm). As the plant developed to the stage of differentiation of the capitulum and remained stable, a similar tendency was detected for cynaroside (0.4–0.16 % dm) and scolymoside (0.7–0.15 % dm), while the behaviour of cynarin was just the opposite, increasing gradually as the plant grew (0.01–0.05 % dm).

Hydroxymethyl acrylic acid was isolated from artichoke leaves (Bogaert et al. 1974). Two phenolic glucoside gallates, 2-methoxy-4-(2,3-dihydroxy-propionyl)-phenyl-1-*O*-(6'-*O*-galloyl)- β -D-glucopyranoside and 4-hydroxy-3-methoxy-phenyl-1-*O*-(6'-*O*-galloyl)- β -D-glucopyranoside, were isolated from the leaves (Liu et al. 2009b). A sesquiterpene lactone cynarolide was isolated from artichoke leaves (Drozd 1968). Two guaiane-type sesquiterpene lactones, cynarinins A and B, together with seven known compounds, cynarascoside C, cynaropicrin, aguerin B, grosheimin, aguerin A dehydrocynaropicrin and cynaratriol, were isolated from aerial part of *Cynara scolymus* (Li et al. 2005). Guaianolides, cynaropicrin and grosheimin, isolated from artichoke leaves were found to be associated with the leaf bitterness (Cravotto et al. 2005). Bioconversion of the chemicals generated 15 sesquiterpene lactone derivatives which were subjected to a taste sensory panel. Bitterness was markedly abated by either the loss of exomethylenes or the opening of the lactone ring. The bitterness of sesquiterpene lactones cynaropicrin

and grosheimin derivatives was found not to be directly related to molecular polarity (Scotti et al. 2007). Cyanaropicrin, the bitter principle was found only in the green aerial parts in the stem sprouts, leaf stalks and green buds (up to 0.6 %) and in leaf lamina 0.5–4.5 % (in one case to 6.5 %) (Schneider and Thiele 2009). Young leaves contained more bitter principle than old ones. The top of the leaves showed 80 % more bitter substance than the leaf base. No bitter substance was found in the roots, completely developed blossoms and fruits. Three new guaianolides, 11-*H*-13-ethylsulfonylgrosheimin (grosulfheimin); 8-deoxy-11,13-dihydroxygrosheimin; and 8-deoxy-11-hydroxy-13-chlorogrosheimin and 8-epigrosheimin were isolated from the leaves (Barbetti et al. 1993). Other guaianolides, cynaropicrin, 3-deidrocynaropicrin, grosheimin, cynarolide and cynaratriol, had been isolated from artichoke (Barbetti et al. 1992; Jouany et al. 1975; Bernhard et al. 1979; Bernhard 1982). Besides cynaratriol, its derivatives 3,11,13-triacetylcynaratriol and 3,13-dibenzoyl-cynaratriol were also identified from the leaves (Bernhard 1982). A guaiane-type sesquiterpene lactone, 3 β , 8 α , 11 β , 13-tetrahydroxy-10(14)-guaien-1 α , 4 β , 5 α , 6 β *H*-6 α , 12-olide, and a known sesquiterpene lactone, cynarinin A, were isolated from the leaves (Liu et al. 2009a).

Apigenin 7-*O*-glucoside, cynarin, narirutin, gallic acid and caffeic acid were found as the main flavonoids and phenolic constituents in all parts of artichoke (flowers, leaves, roots, stems, stumps) (Thi and Park 2008). Water extraction gave higher value of total phenolic compounds and flavonoids than that by methanol or methanol:water extractions. Artichoke stem was found to be rich in non-starch polysaccharide (NSP) (\sim 38 g NSP/kg) and was similar to the receptacle (\sim 34 g NSP/kg), but bracts were heavily lignified; the stem could prove useful as sources of pectic polysaccharide-rich supplements (Femenia et al. 1998).

In commercially available artichoke leaf extract, the following compounds were identified: 8-deoxy-11-hydroxy-13-chlorogrosheimin, cryptochlorogenic acid, chlorogenic acid, neochlorogenic acid, cynarin, cynaratriol (tentatively),

grosheimin, 8-deoxy-11,13-dihydroxygrosheimin, luteolin-7-*O*-rutinoside, luteolin-7-*O*-glucoside and cynaropicrin (Fritsche et al. 2002). The concentration of the compounds, namely, chlorogenic acid, cynarin and luteolin-7-*O*-glucoside, was in the range of 0.35–18.34, n.d.–1.02, 0.04–10.65 mg/g, respectively. Cynaropicrin, the predominant bitter artichoke leaf principle, was present at concentrations between <0.06 and 22.6 mg/g.

Ribulose-1,5-diphosphate carboxylase in artichoke leaves was separated, purified and characterized (Pacoda et al. 1985; Cardinali et al. 1986; Miceli et al. 1986). Cardinali et al. (2012) reported that the cationic peroxidase isoenzyme (CysPrx) isolated from artichoke leaves possessed some interesting properties, suggesting that CysPrx could be considered as a potential candidate for industrial peroxidase application. In addition, from the CysPrx sequence, two full-length cDNAs, CysPrx1 and CysPrx2, differing for three amino acids, were isolated.

Seed Phytochemicals

Artichoke seeds were found to have crude protein 21.6 %, crude fibre 17.1 %, crude oil 24.05 % and ash 3.8 % (Foti et al. 1999). Artichoke seed oil was found to be an unsaturated semi-drying oil, with a high saponification value and acidic. It thus would require purification before used as edible oil. The fatty acid composition showed a high content of polyunsaturated acids (oleic acid 26.73 %, linoleic acid 58.89 %, linolenic acid 0.25 %) and to contain cholesterol (0.2 %), campesterol (12.8 %), Δ^5 -stigmasterol (16.2 %), β -sitosterol (45.6 %), Δ^7 -stigmasterol and Δ^7 -avenasterol (18.4–6.6 %). The oil had a yield of 20.5 %, free acidity (oleic acid) 11.3 %, acid value 22.4 mg/g, iodine value 108.4 g/100 g, unsaponifiable matter 0.9 %, mean molecular mass 306.2 and refractive index 1.4682 (25 °C) (Miceli and De Leo 1996).

Artichoke seed oil was found to be rich in oleic and linoleic acids (Hassanein et al. 2011). The fatty acid profile of artichoke oil comprised 14:0 (0.1 %), 16:0 (11.3 %), 16:1 (0.1 %), 18:0

(3.2 %), 18:1 *n*-9 (30.2 %), 18:1 *n*-7 (0.70 %), 18:2 (53.5 %), 20:0 (0.40 %), 20:1 (0.20 %) 24:0 (0.30 %). Among the triacylglycerols (TAGs), LLL, LLO LLP LOO and LOP were the major components in artichoke seed oil (L=linoleic, O=oleic, P=palmitic). Artichoke seed oil had a whole sterol content (as silyl derivatives) of 1.2 % of the total lipids and had high content of 5-stigmasterol (22.7 %), β -sitosterol (33.1 %) and 7-stigmasterol (25.7 %) and also possessed campesterol (9.5 %), avenasterol (6.4 %), spinasterol (2.2 %) and isofucosterol (0.4 %). The total content of free sterol (FS) and acylated sterol (AS) as 9-anthrolynitrile derivatives isolated from the oil was 390 mg/100 g oil (0.39 % of total lipid) comprising 280 mg/100 mg of free sterol and 110 mg/100 g acylated sterol. Both FS and AS showed the presence of β -sitosterol, isofucosterol, 7-stigmasterol, avenasterol, spinasterol and β -stigmasterol/campesterol (inseparable pair). Artichoke oil also had high content (1,000 ppm) of free sterylglycerols (FSG) (687 ppm) and acylated sterylglycerols (ASG) (313 ppm) as 1-anthrolynitrile derivatives. It was found that β -sitosterol was the major component in both FSG and ASG fractions, followed by campe-/stigma-SG, isofuco-SG, 7-stigma-SG and spina-SG. Artichoke oil was found to have 311 ppm total tocopherols comprising 96.5 % α -tocopherol, 2.5 % γ -tocopherol and 1.0 % δ -tocopherol.

Seeds and leaves of the artichoke had been reported to contain different constituents such as caffeoylquinic acid derivatives, mono- and di-caffeoylquinic acids, bitter sesquiterpene such as cynaratriol and cynaropicrin and flavonoids glycosides like apigenin, luteolin, cynaroside, scolymoside, quercetin and others (Georgieva et al. 2011). The content of total phenolics, chlorogenic acid and 1.5 dicaffeoyl-quinic-acid (cynarin) in germinating seeds varied considerably between different genetic lines and were higher than that reported in artichoke leaves (Ben-Hod et al. 1992). The authors concluded that compared to the traditional extraction from leaves, germinating seeds offer a richer and more dependable source for cynarin supply.

According to Maccarone et al. (1999), *Cynara* species grain oil especially cardoon had superior

alimentary quality with a high content of oleic and linoleic acids in a balanced ratio, a good amount of α -tocopherol and low amounts of free acids, peroxides, saturated and linolenic acids. Triacylglycerols were the dominant constituents together with very little amounts of phospholipids and glycolipids. Curt et al. (2002) reported a range of 20–31.6 % seed oil content for *C. cardunculus*. *Cynara* seed oil profile was characterized in terms of major fatty acids as 10.7 % palmitic, 3.7 % stearic, 25.0 % oleic and 59.7 % linoleic.

Plant Biomass/Root Phytochemicals

At harvest the total biomass and root production, averaged for all *Cynara cardunculus* genotypes, were 20.4 and 9.8 t DM/ha; they were influenced by genotype (Raccuia and Melilli 2004). On average for all of the genotypes, the roots showed a total sugar content of 367 g DM/kg, with a cv. of 17.1 %; the main compound was inulin (85.0 % of total sugars). The wild cardoon 'SR1' showed the highest total sugar content (470 g/kg DM). On average for all of the genotypes, the total sugar and inulin yields were 3.6 and 3.0 t/ha, respectively. Studies showed that globe artichoke (*Cynara cardunculus* subsp. *scolymus*) crop for heads utilization, at the end of their harvest, gave a remaining above-ground biomass production, on average of all genotypes, of 10.3 t/ha DM with a range of 5.7 to 15.7 t/ha of DM, partitioned between leaves (53.4 %) and stalks (47.6 %) (Raccuia et al. 2004b). The root yield resulted on average of all genotypes 5.7 t/ha of DM. The total extracted sugars from roots resulted on average of all genotypes, 249 g/kg of DM, where inulin accounted for 89.4 % of total sugars. Root total sugars yield resulted on average of all genotypes 1.41 t/ha.

Artichoke By-Products/Waste Phytochemicals

Artichoke by-products such as leaves, external bracts and stems that are produced by the artichoke-processing industry represent a huge amount of

discarded material (about 80–85 % of the total biomass of the plant), which could be used as a source of inulin but also of phenolics especially chlorogenic acid and 1,5-*O*-dicaffeoylquinic, 3,5-*O*-dicaffeoylquinic and 3,4-*O*-dicaffeoylquinic acids and should be considered as a raw material for the production of natural nontoxic food additives and nutraceuticals (Lattanzio et al. 2005, 2009; Ceccarelli et al. 2010).

In Spain, a leading artichoke producer in Europe, the residues proceeding from artichoke industry can form up to 60 % of the harvested plant material. Forty-five phenolic compounds were identified in artichoke waste (Sánchez-Rabaneda et al. 2003): gallic acid; caffeoylquinic acid 1,2,3; dicaffeoylquinic acid 1,2,3,4,5,6,7; protocatechuic acid; esculin; chlorogenic acid; *p*-coumaric acid-*O*-glucoside isomers 1 and 2; eriodictyol-glucuronide; rutin (quercetin-3-*O*-rutinoside); dicaffeoylquinic acid derivative; hyperoside (quercetin-3-*O*-galactoside); luteolin-7-*O*-rutinoside; cynaroside (luteolin-7-*O*-glucoside); isoquercitrin (quercetin-3-*O*-glucoside); luteolin-7-*O*-glucuronide; luteolin-7-*O*-galactoside; naringenin-*O*-hexoside; avicularin (quercetin-3-*O*-arabinoside); isorhoifolin (apigenin-7-*O*-rutinoside); quercetin-*O*-pentoside; quercitrin (quercetin-3-*O*-rhamnoside); luteolin-7-*O*-neohesperidoside; apigenin-*O*-glucoside; prunin (naringenin-7-*O*-glucoside); naringin (naringenin-7-*O*-neohesperidoside); scolimoside (luteolin-7-*O*-rhamnoside); apigenin-7-*O*-glucuronide; quercetin-*O*-pentoside; phloridzin (phloretin-2-*O*-glucoside); feruloylquinic acid-*O*-glucoside; luteolin; quercetin; naringenin; and apigenin chrysoeriol. Caffeoylquinic and dicaffeoylquinic acids were the main compounds in the waste residue. A high molecular weight inulin was fabricated from artichoke agroindustrial wastes using environmentally benign aqueous extraction procedures (Lopez-Molina et al. 2005). The main constituent monosaccharide in artichoke inulin was fructose, and its degradation by inulinase indicated that it contained the expected beta-2,1-fructan bonds. Its FT-IR spectrum was identical to that of chicory inulin. The data indicated that artichoke inulin will be suitable for use in a wide range of food applications.

In various molecular, cellular and in-vivo test studies, artichoke (*Cynara scolymus*) leaf extracts showed antioxidative, hepatoprotective, antimicrobial, antiviral, anticancer, urinate, choleric and anticholestatic effects as well as inhibitory actions on cholesterol biosynthesis and LDL oxidation (Kraft 1997; Lattanzio et al. 2009). The antidyspeptic actions were mainly based on increased cholerisis. Regarding clinical data, lipid-lowering, antiemetic, spasmolytic, choleric and carminative effects had been described, along with good tolerance and a low incidence of side effects. The results of several clinical investigations showed the efficacy and safety of artichoke extracts (*Cynara scolymus*) in the treatment of hepato-biliary dysfunction and digestive complaints, such as sensation of fullness, loss of appetite, nausea and abdominal pain (Wegener and Fintelmann 1999). Earlier findings on a lipid-lowering and hepatoprotective effects were confirmed, and flavonoids and caffeoylquinic acids were reported to be mainly responsible for the observed actions. These and other pharmacological properties of artichoke are elaborated below.

Antioxidant Activity

In ABTS and DPPH tests, turmeric extract was found to be the most active, followed by artichoke and dandelion (Menghini et al. 2010). A luteolin-rich artichoke extract retarded low-density lipoprotein (LDL) oxidation in a dose-dependent manner as measured by a prolongation of the lag phase to conjugated diene formation, a decrease in the rate of propagation, and a sparing of endogenous LDL α -tocopherol during oxidation (Brown and Rice-Evans 1998). The pure aglycone, luteolin (1 μ M), demonstrated an efficacy similar to that of 20 μ g/ml artichoke extract in inhibiting lipid peroxidation. Luteolin-7-*O*-glucoside, one of the glycosylated forms in the diet, also demonstrated a dose-dependent reduction of LDL oxidation that was less effective than that of luteolin. Studies of the copper-chelating properties of luteolin-7-*O*-glucoside and luteolin suggested a potential role for chelation in the antioxidative effects of artichoke

extract. The results demonstrated that the antioxidant activity of the artichoke extract was related in part to its constituent flavonoids which acted as hydrogen donors and metal ion chelators, and the effectiveness was further influenced by their partitioning between aqueous and lipophilic phases.

The crude flower head and leaf extracts and different phenolic fractions tested showed good antioxidant activity in the control of the oxidative damage caused by peroxy radicals (the β -carotene/linoleate assay) (Lattanzio et al. 2005). All phenolics exhibited good antioxidant activity against peroxy and hydroxyl radicals when assessed using the β -carotene/linoleate assay and the metmyoglobin assay. The same phenolics showed a lower activity when assessed using the deoxyribose assay. Overall, luteolin, caffeoylquinic acids and hydrolyzable tannins, being the most representative artichoke phenolics, may be considered the phenolic constituents responsible for the antioxidant properties of artichoke extracts. In addition other phenolics present in the extracts such as *p*-coumaric, ferulic, vanillic, syringic acids and apigenin-7-glucoside may contribute to the total antioxidant capacity of the extracts.

Artichoke leaf extract exerted a concentration-dependent inhibition of oxidative stress when human leukocytes were stimulated with agents that generated reactive oxygen species (ROS): hydrogen peroxide, phorbol-12-myristate-13-acetate (PMA) and *N*-formyl-methionyl-leucyl-phenylalanine (FMLP) (Perez-Garcia et al. 2000). Cynarin, caffeic acid, chlorogenic acid and luteolin, constituents of artichoke leaf extract, also exhibited a concentration-dependent inhibitory activity in the above models, contributing to the antioxidant activity of the extract in human neutrophils.

The 75 % ethanol artichoke leaf extract exhibited the highest antioxidant activity as evaluated by 2,2-diphenyl-1-picrylhydrazyl (DPPH) assay as well as yielded the largest quantity of polyphenolic compounds (Vamanu et al. 2011). The optimum concentration of 10 mg/ml gave maximum antioxidant activity of 65.15 %. The MIC values obtained using the freeze-dried extract ranged from 5.0 to 15.0 mg/ml. Total phenolic content

varied from 2.12 to 30.38 mg/g of the extract. In separate studies, the ethanol extracts prepared from *Cynara scolymus* seeds and leaves were found to have DPPH radical scavenging activities (Georgieva et al. 2011). At any studied concentration of the seeds extract, the percent of the scavenged DPPH radicals was considerably higher than that calculated for the leaves extract. All investigated individual artichoke compounds from commercially artichoke leaf extract—chlorogenic acid, cynarin, luteolin and luteolin-7-*O*-glucoside—showed a remarkable antioxidative effect, chlorogenic acid being the strongest antioxidant compound (Fritsche et al. 2002).

Antioxidant phenolics were extracted from artichoke by-products: raw artichoke (RA), blanched (thermally treated) artichoke (BA) and artichoke blanching waters (ABW) by both methanol and water extractions (Llorach et al. 2002). Phenolic contents (expressed as caffeic acid derivatives) (grams per 100 g of dry extract) were 15.4 and 9.9 for RA when extracted with methanol and water, respectively; 24.3 and 10.3 for BA when extracted with methanol and water, respectively; and finally, 11.3 g of phenolics/100 ml of ABW. The artichoke extracts from industrial by-products showed a high free radical scavenging activity (versus both DPPH* and ABTS*+radicals) as well as capacity to inhibit lipid peroxidation (ferric thiocyanate method). The results suggested the possible use of artichoke extracts from industrial by-products as ingredients to functionalize foodstuffs (to decrease lipid peroxidation and to increase health-promoting properties). In another study one gram (dry matter) of artichoke was found to have a DPPH(*) activity and a FRAP value in-vitro equivalent to those of 29.2 and 62.6 mg of vitamin C and to those of 77.9 and 159 mg of vitamin E, respectively (Jiménez-Escrig et al. 2003). Artichoke extracts showed good efficiency in the inhibition in vitro of low-density lipoprotein oxidation. Neither ferric-reducing ability nor 2,2'-azinobis(3-ethylbenzothiazolin-6-sulfonate) radical scavenging activity was modified in the rat plasma of the artichoke group with respect to the control group. Among different antioxidant enzymes measured (superoxide dismutase, glutathione

peroxidase, glutathione reductase and catalase) in erythrocytes, only glutathione peroxidase activity was elevated in the artichoke group compared to the control group. 2-Aminoadipic semialdehyde, a protein oxidation biomarker, was decreased in plasma proteins and haemoglobin in the artichoke-fed group versus the control group. The results confirmed the in-vitro protective oxidative activity of artichoke in a rat model.

Studies demonstrated that artichoke polyphenolic extract protected cultured rat hepatocytes from the oxidative stress caused by glucose oxidase, comparable to the well-known antioxidant, *N,N'*-diphenyl-*p*-phenylenediamine (DPPD) (Miccadei et al. 2008). Further, the extract as well as chlorogenic acid prevented the loss of total glutathione and the accumulation of malondialdehyde. Artichoke leaf aqueous extracts exhibited a dose-dependent free radical scavenging effect of DPPH and an inhibitory effect of xanthine oxidase (Zan et al. 2013). The extract was found to contain phenolic compounds, flavonoids and saponins such as chlorogenic acid, caffeic acid, isoquercetrin and rutin.

The antioxidant capacity of cooked artichokes, measured by three different assays, enormously increased after cooking, particularly after steaming (up to 15-fold) and boiling (up to 8-fold) (Ferracane et al. 2008). Boiling increased the concentration of dicaffeoylquinic acid isomers much more than steaming or frying which showed similar patterns of dicaffeoylquinic concentrations. However, all cooking practices, particularly frying, decreased flavonoid concentration.

In double-blinded study carried out in 22 members of the Polish rowing team who were randomly assigned to a supplemented group ($n=12$), receiving 1 gelatin capsule containing 400 mg of artichoke leaf extract three times a day for 5 weeks, or a placebo group ($n=10$), plasma total antioxidant capacity (TAC) was significantly higher in the supplemented group than in the placebo group during restitution (Skarpanska-Stejnborn et al. 2008). Serum total cholesterol levels at the end of the study were significantly lower in the supplemented group than in the placebo group. The authors concluded that consuming artichoke leaf extract, a natural vegetable

preparation of high antioxidant potential, resulted in higher plasma TAC than placebo but did not limit oxidative damage to erythrocytes in competitive rowers subjected to strenuous training.

The ethanol extract and fractions (chloroform, ethyl acetate and *n*-butanol) of the ethanol extract of fresh involucre bracts of cardoon, *Cynara cardunculus*, exhibited concentration-dependent antioxidant activity in the FRAP (ferric reducing antioxidant power) assay and scavenging of 2,2-diphenyl-1-picrylhydrazyl (DPPH) radical assays (Kukić et al. 2008).

Antidyspeptic Activity

A significant increase in bile flow was observed in anesthetized Wistar rats after acute treatment with artichoke leaf extract as well as after repeated administration (Sánchez-Rabenedo et al. 2003). The choleretic effects of artichoke extract were similar to those of the reference antidyspeptic compound dehydrocholic acid (DHCA).

In a randomized placebo-controlled double-blind cross-over study of 20 subjects, administration of a standardized, artichoke extract Hepar-SL forte was found to have a choleretic effect (Kirchhoff et al. 1994). At 120 and 150 minutes the volume of bile secreted under the active treatment was also significantly higher than under the placebo. In the placebo group, bile secretion fell below the initial level after 3 hours. An effective period of about 120–150 minutes was regarded as satisfactory to influence enzymatic digestion and the motor function of the intestine when the test substance was given postprandially. No side effects or changes in the laboratory parameters in connection with the experiment were observed. Results indicated that artichoke extract could be recommended for the treatment of dyspepsia, especially when the cause may be attributed to dyskinesia of the bile ducts or disorder in the assimilation of fat.

In postmarketing surveillance (phase IV) studies patients with non-specific gastrointestinal complaints receiving treatment with globe artichoke leaf extract (Hepar-SL forte; up to 1.92 g daily for 6 weeks (Fintelmann and Menssen 1996) or

6 months (Fintelmann and Petrowicz 1998) were monitored. In one study involving 533 patients with non-specific gastrointestinal complaints, including dyspepsia, functional biliary tract complaints, constipation and gastric irritation, seven adverse events (weakness, hunger, flatulence) were reported (1.3 % of participants), but no serious adverse events were reported (Fintelmann and Menssen 1996). In the second postmarketing surveillance study involving 203 patients with symptoms of dyspepsia who received globe artichoke leaf extract up to 1.92 g daily for up to 6 months, no adverse events were recorded (Fintelmann and Petrowicz 1998). The physicians' overall judgement of tolerability was given as 'good' or 'excellent' in 98.5 % of cases. In another postmarketing surveillance study for artichoke leaf extract in a sub-group of patients with irritable bowel syndrome (IBS) symptoms, analysis of data revealed significant reductions in the severity of symptoms and favourable evaluations of overall effectiveness by both physicians and patients (Walker et al. 2001). Additionally, 96 % of patients rated artichoke extract as better than or at least equal to previous therapies administered for their symptoms, and the tolerability of the extract was very good.

Studies by Marakis et al. (2002) found that artichoke leaf extract showed promise in ameliorating upper gastrointestinal symptoms and improving quality of life in otherwise healthy subjects suffering from dyspepsia. Of the 516 participants, 454 completed the study. There was a significant reduction of all dyspeptic symptoms, with an average reduction of 40 % in global dyspepsia score for both dosage groups of 320 or 640 mg daily. There were no differences in the primary outcome measures between the two groups, but relief of state anxiety, a secondary outcome, was greater with the higher dosage. Health-related quality of life was significantly improved in both groups compared with baseline. The efficacy of artichoke leaf extract treatment of patients with functional dyspepsia (129 artichoke treatment, 115 placebo) was assessed in a 6-week, double-blind, randomized controlled trial (Holtmann et al. 2003). The overall symptom improvement over the 6 weeks of treatment was

significantly greater with artichoke extract than with the placebo. Similarly, patients treated with artichoke extract showed significantly greater improvement in the global quality-of-life scores (NDI) compared with the placebo-treated patients.

In a subset analysis of a previous dose-ranging, open, postal study in adults (208) suffering from dyspepsia, 2 months intervention of artichoke leaf extract was found to ameliorate symptoms of irritable bowel syndrome (IBS) in otherwise healthy volunteers (Bundy et al. 2004). A significant shift in self-reported usual bowel pattern away from 'alternating constipation/diarrhoea' towards 'normal' was observed. Nepean Dyspepsia Index (NDI) total symptom score significantly decreased by 41 % after artichoke treatment. Similarly, there was a significant 20 % improvement in the NDI total quality-of-life (QOL) score in the subset after treatment.

Treatment of a cohort of patients with a clinical diagnosis of functional dyspepsia for 60 days with Cinarepa, a commercial mixture of dry extracts of artichoke leaf (*Cynara scolymus*) 15 % of chlorogenic acid (150 mg per capsule), dandelion radix (*Taraxacum officinalis*) 2 % of inulin, turmeric rhizome (*Curcuma longa*) 95 % of curcumin and rosemary bud essential oil micro-encapsulated (*Rosmarinus officinalis*), was found to ameliorate severity of dyspepsia symptoms (Sannia 2010). Global clinical response, defined as a 50 % reduction in the total scores of all symptoms, was recorded in 38 % of patients at 30 days and in 79 % at 60 days. At 60 days, total cholesterol, LDL and triglyceride levels had decreased by 6–8 % over baseline values; transaminase (AST, ALT) and gamma GT concentrations had diminished by 13–20 U/l in patients with relatively elevated baseline values.

Hepatoprotective Activity

In rats receiving ethanol and 1,5-dicaffeoylquinic acid (cynarin) simultaneously, a distinct reduction of the serum and hepatic cholesterol levels was observed (Wójcicki 1978). In contrast, rats treated with ethanol alone, the serum and hepatic cholesterol showed a significant rise of 44 and

75 %, respectively. Of the polyphenolic compounds of artichoke, only cynarin and, to a lesser extent, caffeic acid showed hepatoprotective activity against CCl_4 toxicity in isolated rat hepatocytes (Adzet et al. 1987).

The results of in-vitro studies indicated artichoke extracts had a marked antioxidative and protective potential (Gebhardt 1997). Addition of artichoke extracts to primary rat hepatocyte cultures exposed to *tert*-butylhydroperoxide (*t*-BHP) or cumene hydroperoxide did not affect basal malondialdehyde (MDA) production but prevented the hydroperoxide-induced increase of MDA formation in a concentration-dependent manner when presented simultaneously or prior to the peroxides. The artichoke extracts did not affect the cellular level of glutathione (GSH) but diminished the loss of total GSH and the cellular leakage of GSSG resulting from exposure to *t*-BHP. Chlorogenic acid and cynarin accounted for only part of the antioxidative principle of the extracts which was resistant against tryptic digestion, boiling, acidification and other treatments but was slightly sensitive to alkalization. In another study, aqueous artichoke extracts added prior or simultaneously with *tert*-butylhydroperoxide (*t*-BHP) to primary cultures of rat hepatocytes reduced both lipid peroxidation and cytotoxicity with EC_{50} values of about 95 and 12 μg artichoke powder/ml, respectively (Gebhardt and Fausel 1997). Further, the extract prevented the loss of intracellular glutathione caused by *t*-BHP. Several polyphenolic and flavonoid constituents of AE were found to reduce malonaldehyde (MDA) production. EC_{50} values were 8.1, 12.5, 15.2 and 28 $\mu\text{g}/\text{ml}$ for caffeic acid, chlorogenic acid, cynarin and cynarosid, respectively. A similar ranking for the extract and constituents was found when using the chemiluminescent xanthine oxidase assay for determination of the antioxidative potency, but EC_{50} values were consistently lower. Regarding the hepatoprotective effect, that is, prevention of LDH (lactate dehydrogenase) leakage, all constituents were almost equipotent and EC_{50} values were lower than for MDA production. Other studies showed artichoke leaf extracts exerted a potent anticholestatic action in primary cultured rat hepatocytes

at least in the case of tauroolithocholate-induced cholestasis (Gebhardt 2001, 2002b). Tauroolithocholate-induced bizarre bile canalicular membrane distortions could be prevented by artichoke leaf extracts in a dose-dependent manner when added simultaneously with the bile acid. Flavonoids and their metabolites flavonol luteolin and, to a lesser extent, by luteolin-7-*O*-glucoside, may contribute significantly to this effect. Chlorogenic acid and 1,5-dicaffeoyl quinic acid were almost ineffective.

Speroni et al. (2003) showed that the *Cynara scolymus* leaf extract with the highest content in phenolic derivatives (GAE) exerted the major effect on bile flow and liver protection. Also the results of the antioxidant capacity (BR) of the different preparations were in good agreement with the results obtained in-vivo. On the contrary, administering rats with doses of chlorogenic acid, equivalent to those present in this extract, did not elicit any choleretic or protective action. They suggested that caffeoyl derivatives had a role in the therapeutic properties of *C. scolymus* extracts, as reported in literature for 'in-vitro' studies, but when administered alone, they were not so effective in exerting this effect. Separate studies showed that in rats pretreated with artichoke leaf extract, significant decreases in plasma transaminase activities and amelioration in histopathological changes in the liver were observed following carbon tetrachloride (CCl_4) treatment as compared to CCl_4 -treated rats (Mehmetçik et al. 2008). In addition, hepatic malondialdehyde and diene conjugate levels decreased, but glutathione levels and glutathione peroxidase activities increased without any change in other antioxidant parameters following CCl_4 treatment in artichoke-pretreated rats. Their findings indicated that in-vivo artichoke extract administration may be useful for the prevention of oxidative stress-induced hepatotoxicity.

Antihypercholesterolemic Antihyperlipidemic Activity

Cynara scolymus was one of seven plant species that had preclinical data that indicated a potential

role in the control of certain conditions which are associated with obesity, such as hyperlipidaemia (Dickel et al. 2007).

In-Vitro Studies

High-dose aqueous extracts from artichoke leaves were found to inhibit cholesterol biosynthesis from ^{14}C -acetate in primary cultured rat hepatocytes in a concentration-dependent biphasic manner with moderate inhibition (approximately 20 %) between 0.007 and 0.1 mg/ml and more strong inhibition at 1 mg/ml (Gebhardt 1998). It was found that an indirect modulation of 3-hydroxy-3-methylglutaryl-CoA (HMG-CoA)-reductase activity was the most likely inhibitory mechanism of the artichoke extracts. Screening of several known constituents of artichoke extracts revealed that cynaroside and particularly its aglycone luteolin were mainly responsible for inhibition, whereas chlorogenic acid was much less effective and caffeic acid, cynarin and other dicaffeoylquinic acids were without significant influence. Also, luteolin also efficiently blocked the insulin effect on cholesterol biosynthesis. The results demonstrated that artichoke extracts may inhibit hepatic cholesterol biosynthesis in an indirect but efficient manner and, thus, may contribute via this action to its hypolipidemic influence in man. In a subsequent paper, high-dose aqueous artichoke leaf extracts were found to inhibit cholesterol biosynthesis from ^{14}C -acetate rather moderately in HepG2 cells in contrast to primary cultured rat hepatocytes in which the inhibition was stronger (Gebhardt 2002a). Preincubation of the extracts with beta-glucosidase considerably reinforced the inhibition. At extract concentration of 0.2 mg/ml, almost 60 % inhibition was observed. Cytotoxic effects detected by the MTT-assay were restricted to higher concentrations of the extracts with and without beta-glucosidase pretreatment. It was demonstrated that cynaroside was one of the targets of beta-glucosidase and that the liberated luteolin was responsible for the inhibitory effect. Direct measurements of beta-glucosidase activity in rat hepatocytes and HepG2 cells revealed that endogenous enzyme activity in hepatocytes may be sufficient to

convert cynaroside to its aglycone, while in HepG2 cells this may not be the case.

Of all individual artichoke compounds from commercially artichoke leaf extract, chlorogenic acid showed a strong, dose-dependent linear 3HMG-CoA reductase inhibitory effect at concentrations between 5 and 50 mg/ml (Fritsche et al. 2002). Luteolin and luteolin-7-*O*-glucoside showed an even stronger inhibitory effect at 10 mg/ml (relative HMG-CoA reductase activity: 2.4 and 6.5 %, respectively, compared to 26.5 % activity after chlorogenic acid treatment). All studied commercially available artichoke leaf extracts showed a moderate inhibitory effect at 10 mg/ml.

Animal Studies

Results of several earlier animal studies suggested that artichoke and cardoon extracts exerted a marked reduction in serum cholesterol and triglyceride levels after experimentally induced hypercholesterolaemia (Samochowiec 1962a, b; Lietti 1977).

The methanol artichoke leaf extract was found to suppress serum triglyceride elevation in olive oil-loaded mice (Shimoda et al. 2003). The sesquiterpenes cynaropicrin, aguerin B and grosheimin were isolated as the active components together with new sesquiterpene glycosides (cynarascolosides A, B and C). Further, inhibition of gastric emptying was shown to be partly involved in antihyperlipidemic activity. Studies on the effect of the artichoke extract on oxidation of palmitic-1- ^{14}C acid administered intravenously to rats at a dose 25 and 50 mg/kg body weight demonstrated marked dose-dependent enhancement of both $^{14}\text{CO}_2$ expiration rate and $^{14}\text{CO}_2$ recovery in the expired air (Juzyszyn et al. 2008a). The extract suppressed accumulation of palmitic-1- ^{14}C acid in serum lipids and epididymal fat pad tissue in a dose-dependent manner. The results demonstrated that artichoke extract possessed stimulatory properties with respect to oxidation of palmitic acid administered to rats and provided new information on the mechanism of antilipidemic activity of the extract associated with activation of lipid oxidation in rats.

Significant decreases in serum malondialdehyde (MDA) and diene conjugate levels and

increases in plasma antioxidant activity were detected in serum in artichoke-treated hypercholesterolemic rats (Küskü-Kiraz et al. 2010). Endogenous diene conjugate and copper-induced MDA levels were also lower in LDL+VLDL fraction due to artichoke-treatment in hypercholesterolemic rats. Their results indicated that artichoke leaf extract may be useful for the prevention of hypercholesterolaemia-induced pro-oxidant state in LDL+VLDL fraction and the reduction of increased serum cholesterol and triglyceride levels. Küçükgergin et al. (2010) found that serum cholesterol and triglyceride levels and ratio of cholesterol to high-density lipoprotein (HDL)-cholesterol decreased in hypercholesterolemic rats treated with artichoke leaf extract, but liver cholesterol and triglyceride levels remained unchanged. Significant decreases in hepatic and cardiac malondialdehyde (MDA) and diene conjugate levels and increases in hepatic vitamin E and glutathione peroxidase activities were observed in artichoke-treated hypercholesterolemic rats. Their results indicated that artichoke leaf extract decreased serum lipids and hypercholesterolaemia-induced pro-oxidant state in both hepatic and cardiac tissues. In another study, treatment with artichoke flowering head extract (500–1,500 mg/kg by gavage) resulted in a significant decrease of postprandial glycaemia in both nonselected Wistar and genetically obese Zucker rats (Fantini et al. 2011). The lack of any fibre content in this *Cynara scolymus* flowering head extract excluded the involvement of dietary fibres in glycaemia reduction. The results obtained suggested a hypoglycaemic effect of an artichoke preparation in laboratory rodents and confirmed previous observations made in humans.

Studies showed that after 42 days of feeding, artichoke leaf extract (ALE)-fed male Golden Syrian hamsters had significantly lower total cholesterol (15 %), non-HDL-cholesterol (30 %) and triglycerides (22 %) and female hamsters fed ALE showed reductions of 15 % for total cholesterol, 29 % for non-HDL-cholesterol and 29 % for triglycerides compared with controls (Qiang et al. 2012). Total neutral sterol and bile acids concentrations increased significantly by 50 and 53 % in faecal samples of ALE fed males, and

82.4 and 25 % in ALE fed females compared with controls. The ALE lowered hamster plasma cholesterol levels by a mechanism involving the greater excretion of faecal bile acids and neutral sterols. Studies in hyperlipidemic animal models (10 days and 7 weeks) showed that a treatment combination of artichoke leaf extract, turmeric extract, prickly pear dried leaves and garlic extract prevented dyslipidaemia, decreasing significantly serum LDL levels and LDL/HDL ratio (Qinna et al. 2012). This was mediated partially by the inhibition of HMG-CoA reductase activity by artichoke and prickly pear leaves.

Clinical Studies

Studies demonstrated that the serum level of the lipids decreased after cynarin administration to patients affected with diabetes (Wojcicki and Kadykow 1974). The data obtained in one patient affected with remarkable hyperlipidaemia appeared to confirm the abovementioned action. Studies involving seventeen ambulant outpatients with familial Type IIa or Type IIb hyperlipoproteinaemia found that oral administration with cynarin, the 1,5-dicaffeoyl ester of quinic acid, the constituent of the artichoke at doses of 250 mg, and 750 mg daily for 3 months exerted no hypolipidaemic effect in familial Type II hyperlipoproteinaemia (Heckers et al. 1977). The mean serum cholesterol and triglyceride concentrations were not significantly changed within 3 months.

In a randomized, double-blind, placebo-controlled trial of a globe artichoke leaf extract (Hepar-SL forte; 640 mg three times daily for 12 weeks) involving 44 healthy volunteers, subgroup analysis suggested lipid-lowering effects (cholesterol and triglycerides) with globe artichoke extract for participants with baseline total cholesterol concentrations >210 mg/dl (Petrowicz et al. 1997). Another double-blind, randomized, placebo-controlled, multicenter clinical trial involving 143 adult patients found dry artichoke extract as tablets to be efficacious in treating hyperlipoproteinaemia over 6 weeks (Englisch et al. 2000). The decrease of total cholesterol in the artichoke-treated group was 18.5 % compared to 8.6 % in the placebo group. LDL-cholesterol

decrease in the artichoke-treated group was 22.9 and 6.3 % for placebo. LDL/HDL ratio showed a decrease of 20.2 % in the artichoke-treated group and 7.2 % in the placebo group. There were no drug-related adverse events during this study indicating an excellent tolerability of artichoke dry extract. In a study of 18 moderately hyperlipidemic patients (LDL-cholesterol >130 <200 mg/dl and/or triglycerides >150 <250 mg/dl), supplementation of artichoke juice to an isocaloric hypolipidic diet appeared to positively modulate endothelial function in hypercholesterolaemia (Lupattelli et al. 2004). After artichoke treatment there was an increase of triglycerides and a reduction of total cholesterol, LDL-cholesterol and humoral markers such as vascular cell adhesion molecule-1 (VCAM-1), intercellular adhesion molecule-1 (ICAM-1), and an increase in brachial flow-mediated vasodilation (FVM). Univariate analysis showed that in artichoke patients, changes of VCAM-1 and ICAM-1 were significantly related to changes in brachial FVM.

Studies involving healthy adults with mild to moderate hypercholesterolaemia showed that consumption of artichoke leaf extract resulted in a modest but favourable statistically significant difference in total cholesterol after 12 weeks (Bundy et al. 2008). Plasma total cholesterol decreased in the treatment group by an average of 4.2 % (from 7.16 to 6.86 mmol/l) and increased in the control group by an average of 1.9 %. No significant differences between groups were observed for LDL-cholesterol, HDL-cholesterol or triglyceride levels. In a double-blind, randomized, placebo-controlled trial of 92 overweight subjects with primary mild hypercholesterolaemia, dietary supplementation of artichoke leaf extract for 8 weeks was associated with a significant increase in mean high-density lipoprotein (HDL)-cholesterol and in mean change in HDL-cholesterol (HDL-C) (Rondanelli et al. 2013a). A significantly decreased difference was also found for the mean change in total, low-density lipoprotein (LDL)-cholesterol, total cholesterol/HDL ratio, and LDL/HDL ratio, compared to placebo. The data suggested that artichoke leaf extract could play a relevant role in the management of mild hypercholesterolaemia.

In a double-blind, randomized, parallel-controlled study of 39 subjects from 21 to 55 years with moderate hypercholesterolaemia, daily consumption of a dietary supplementation containing red yeast rice, sugar cane-derived policosanols and artichoke leaf extracts, for 16 weeks, decreased LDL-cholesterol and total cholesterol, providing an interesting, convenient aid in managing mild to moderate hypercholesterolaemia (Ogier et al. 2013).

Review Studies

Wider et al. (2009, 2013) found that data from three randomized controlled trials (262 participants) assessing monopreparations of artichoke leaf extract for treating hypercholesterolaemia met all inclusion criteria. There was an indication that artichoke leaf extract had potential in lowering cholesterol levels; the evidence was, however, as yet not convincing. The limited data on safety suggested only mild, transient, and infrequent adverse events with the short-term use of artichoke leaf extract.

Antihyperglycaemic/Antidiabetic Activity

Studies found that diabetic individuals (15) of both sexes and of age 35–45 years supplemented with wheat biscuits with 4 globe artichoke incorporated wheat biscuits (containing 6 g of processed globe artichoke powder) for the period of 90 days had a significant reduction at one percent level in fasting and postprandial blood glucose compared to the control group (Nazni et al. 2006). Results of the serum lipid profile showed a significant reduction at one percent level in total cholesterol, serum triglyceride, low-density lipoprotein (LDL) and significant increase in high-density lipoprotein (HDL) levels of the artichoke/wheat group compared to the control group. The results recommended that the type 2 diabetic subjects should use globe artichoke vegetable in their food preparation on regular basis which showed good hypoglycaemic and hypolipidemic activities. Studies in rats showed that a mixture of *Phaseolus vulgaris* and *C. scolymus* extracts additively contributed to the reducing effect of

the combination on glycemic rise as it combines the anorectic effect of the *P. vulgaris* extract with the hypoglycaemic effect of both extracts (Loi et al. 2013). The data supported the recent clinical use of the combination of *P. vulgaris* and *C. scolymus* extracts in the control of appetite, food intake and postprandial glycaemia.

In a randomized, double-blind, placebo-controlled clinical trial of 39 overweight subjects (20 supplemented group, 19 placebo group) diet supplementation with a combination of *Phaseolus vulgaris* and *Cynara scolymus*, for 2 months, was found to be useful in the management of overweight and dysglycaemia (Rondanelli et al. 2011). At the end of treatment, the net change of the Haber's mean score on satiation increased significantly in the intervention group. The net change of glycaemia and of the dietary restriction score of the three factor eating questionnaire (TFEQ) were reduced significantly only in the intervention group. Also in the homeostasis model assessment, the body mass index and the susceptibility-to-hunger score of the TFEQ decreased significantly after intervention; these parameters did not change in the controls. In another double-blind, placebo-controlled, randomized clinical trial of 55 overweight subjects with naive impaired fasting glycaemia (fasting blood glucose [FBG]: 6.11 mmol/l), dietary supplementation with artichoke extract for 8 weeks resulted in significant decreases of FBG (−9.6 %), HOMA (homeostatic metabolic assessment) (−11.7 %), glycosylated haemoglobin (−2.3 %), ADAG (A1c-derived average glucose) (−3.1 %), and lipidic pattern compared to placebo (Rondanelli et al. 2013b). The data demonstrated the efficacy of artichoke extract on the reduction of glycometabolic parameters in overweight subjects with impaired fasting glycaemia.

Anticancer Activity

Hexanoic artichoke leaf fraction exhibited considerable cytotoxicity in the brine shrimp *Artemia salina* assay (Noldin et al. 2003). Artichoke extract exhibited antiproliferative activity in a dose-dependent manner against HepG2 cells.

In the same cell line, pre-treatment with the extract was efficient in reducing the release of prostaglandin E2 induced by hydrogen peroxide oxidative stimulus (Menghini et al. 2010).

Two hydroxy taraxastane-type triterpenes, taraxasterol and faradiol, isolated from the flowers showed strong inhibitory activity against 12-*O*-tetradecanoyl-phorbol-13-acetate (TPA)-induced inflammation in mice (Yasukawa et al. 1996). At 0.2 $\mu\text{mol}/\text{mouse}$, these compounds markedly suppressed the tumour-promoting effect of TPA (1 $\mu\text{g}/\text{mouse}$) on skin tumour formation following initiation with 7,12-dimethylbenz[a]anthracene (DMBA). The methanol flower extract of artichoke exhibited marked antitumor activity in an in-vivo two-stage carcinogenesis test in mice, induced by 7,12-dimethylbenz[a]anthracene as an initiator and 12-*O*-tetradecanoylphorbol-13-acetate (TPA) as a promoter (Yasukawa et al. 2010). From the active fraction of the methanol extract, four triterpene alcohols and their corresponding acetates were isolated and identified. These compounds showed marked antiinflammatory effects against TPA-induced inflammation, with a 50 % inhibitory dose of 0.50–0.91 $\mu\text{mol}/\text{ear}$. Studies demonstrated that 10 % fish oil and 1 g% artichoke head or leaves administered to rats for 25 days before diethylnitrosamine (DEN) injection led to significant amelioration of DEN-induced changes in the biochemical parameters (Metwally et al. 2011). The administration of DEN affected the liver cell through occurrence of hepatic cellular degeneration and necrosis. An almost normal histological architecture of the liver, in treated groups, was shown as compared to the controls. The results pointed that 10 % fish oil and 1 g% artichoke succeeded to protect from hepatocellular carcinoma to a certain degree.

Studies showed that the polyphenolic extracts from the edible part of artichokes (AEs) reduced cell viability, inhibited cell growth, triggered apoptotic mechanisms, and showed inhibitory properties against the invasive behaviour of the human breast cancer, oestrogen receptor negative, and MDA-MB231 cancer cell line (Mileo et al. 2012). Importantly, the extract did not have any effect on normal breast epithelial cell line, MCF10A. Chlorogenic acid, the most

representative component of the polyphenolic fraction of artichoke, had no prominent effects on the cell death rate of MDA-MB231 cells. The addition of the extract to the cells rather than chlorogenic acid triggered apoptosis via a mitochondrial and a death-receptor pathway, as shown by the activation of caspase-9 and caspase-8, respectively. Similarly, treatment of human hepatoma HepG2 cells for 24 hours with artichoke polyphenolic extract reduced cell viability in a dose-dependent manner; however, chlorogenic acid had no prominent effects on the cell death rate (Miccadei et al. 2008). Similarly, the extract rather than chlorogenic acid induced apoptosis in HepG2 cells. In separate studies, cynaropicrin and grosheimin isolated from artichoke aerial parts showed weak cytotoxicity against MCF-7 cancer cell line, and other compounds had no obvious activity against the same cell line (Li et al. 2005).

Antiviral Activity

The use of cycloferon and phytopreparations of *Cynara scolymus* in the medical rehabilitation period was found to normalize the elevated proinflammatory cytokines concentration in the blood serum of the patients with chronic viral hepatitis C (Frolov et al. 2012). A pilot study involving 17 patients with chronic hepatitis C found that artichoke leaf extract appeared not effective in mitigating elevated amino transferase levels or viral load compared to baseline levels (Huber et al. 2009). Fatigue and joint problems significantly improved after 4 weeks of treatment; however, after 12 weeks, there was no significant difference to baseline. Tolerability of the extract was rated as good to excellent. Severe side effects did not occur.

Antimicrobial Activity

The dichloromethane extract of artichoke at the MIC concentration of 5 mg/ml completely inhibited the growth with a bactericidal effect on *Staphylococcus aureus*, *Bacillus cereus* and

B. subtilis (Mossi and Echeverrigaray 1999). Five different unidentified components with antimicrobial activity were found. A preliminary antimicrobial disk assay of chloroform, ethyl acetate and *n*-butanol fractions of artichoke leaf extracts showed that the *n*-butanol fraction exhibited the most significant antimicrobial activities against seven bacteria species, four yeasts and four moulds (Zhu et al. 2004). Eight phenolic compounds were isolated from the *n*-butanol-soluble fraction of artichoke leaf extract: four caffeoylquinic acid derivatives, chlorogenic acid (1), cynarin (2), 3,5-di-*O*-caffeoylquinic acid (3) and 4,5-di-*O*-caffeoylquinic acid (4), and the four flavonoids, luteolin-7-rutinoside (5), cynaroside (6), apigenin-7-rutinoside (7) and apigenin-7-*O*- β -D-glucopyranoside (8). Among them, chlorogenic acid, cynarin, luteolin-7-rutinoside and cynaroside exhibited a relatively higher activity than other compounds; in addition, they were more effective against fungi than bacteria. The minimum inhibitory concentrations of these compounds were between 50 and 200 μ g/ml. In subsequent studies, artichoke leaf extract was found to be most effective in vitro against all of the tested organisms: 7 foodborne bacterial pathogens, *Bacillus subtilis*, *Staphylococcus aureus*, *Agrobacterium tumefaciens*, *Micrococcus luteus*, *Escherichia coli*, *Salmonella typhimurium* and *Pseudomonas aeruginosa*, 4 yeasts, *Candida albicans*, *Candida lusitanae*, *Saccharomyces cerevisiae* and *Saccharomyces carlsbergensis*, and 4 molds, *Aspergillus niger*, *Penicillium oxalicum*, *Mucor mucedo* and *Cladosporium cucumerinum* (Zhu et al. 2005a, b). It was followed by the head and stem extracts, and the ethanol fraction showed the most significant antimicrobial activity against all of the tests among 3 soluble fractions of extract, followed by the chloroform and ethyl acetate fractions. The minimum inhibitory concentrations (MICs) of extracts determined by the agar and broth dilution method ranged from 1.25 to 10.0 mg/ml. The MIC of the ethanol fraction of leaf extracts was the lowest compared to the other two extracts. The MIC for fungi was at or below 2.5 mg/ml and for bacteria was at or above 2.5 mg/ml.

C. cardunculus fresh involucre bracts extracts showed antimicrobial activity in vitro against

Salmonella typhimurium, *Escherichia coli*, *Bacillus subtilis*, *Staphylococcus epidermidis*, *Staphylococcus aureus*, as well as micromycetes: *Aspergillus niger*, *Aspergillus ochraceus*, *Aspergillus flavus*, *Penicillium ochrochloron*, *Penicillium funiculosum*, *Trichoderma viride*, *Fusarium tricinctum* and *Alternaria alternata* comparable with standard antibiotics (Kukić et al. 2008). The ethanol artichoke leaf extract showed significant inhibitory activity against the tested strains of *Listeria innocua*, *Staphylococcus aureus* and *Bacillus cereus* with MICs of 5 mg/ml and lower inhibitory activity against *Escherichia coli*, *Pseudomonas aeruginosa*, *Candida albicans* and another *Candida* sp. with MICs of 15 mg/ml (Vamanu et al. 2011).

The extracts of *Acacia farnesiana*, *Artemisia ludoviciana*, *Opuntia ficus-indica*, and *Cynara scolymus* were the most effective in-vitro against *Campylobacter jejuni* and *Campylobacter coli* at minimal bactericidal concentrations (MBCs) of 0.3, 0.5, 0.4 and 2.0 mg/ml, respectively (Castillo et al. 2011). No effect on growth was detected with lower concentrations of extract (25 %, 50 % or 75 % of the MBC). Adherence of *Campylobacter* to Vero cells was significantly affected by all the extracts. *Campylobacter* contamination in foods can cause campylobacteriosis, which can range from asymptomatic to dysentery-type illnesses with severe complications, such as Guillain-Barre syndrome.

Prebiotic/Probiotic Activity

The health-promoting prebiotic effects of artichoke inulin were demonstrated in an extensive microbiological study showing a long-lasting bifidogenic effect on *Bifidobacterium bifidum* cultures and also in mixed cultures of colonic bacteria (Lopez-Molina et al. 2005). Valerio et al. (2006) found that probiotic strains of *Lactobacillus plantarum* and *Lactobacillus paracasei* were able to survive on artichokes for at least 90 days in simulated gastrointestinal digestion. Further, when *L. paracasei* IMPC2.1 was used in an artichoke human feeding study involving four volunteers, the organism could be recovered from

stools. *Cynara scolymus* was found to accumulate about 50–70 g/kg of its fresh weight as inulin-type fructan (Leroy et al. 2010). Inulin fermentation increases gas production and thereby provokes intestinal discomfort in some people. The scientists found that eating stored artichoke led to consumption of an inulin quantity that did not provoke unwanted symptoms related to gas production but sufficient to have a prebiotic effect. Storage time caused a decrease in inulin content and an average degree of polymerization, accompanied by an increase of free fructose and sucrose due to depolymerization of inulin. In a double-blind, placebo-controlled, cross-over study of 32 healthy adults, daily consumption for 10 days of a very-long-chain inulin (VLCI), derived from globe artichoke, was found to significantly increased numbers of faecal bifidobacteria and lactobacilli compared to placebo (Costabile et al. 2010). Additionally, levels of *Atopobium* group significantly increased, while *Bacteroides-Prevotella* numbers were significantly reduced. No significant changes in faecal SCFA concentrations were observed. There were no adverse gastrointestinal symptoms apart from a significant increase in mild and moderate bloating upon VLCI ingestion. The results showed that daily consumption of VLCI extracted from globe artichoke exerted a pronounced prebiotic effect on the human faecal microbiota composition and was well tolerated by all volunteers.

In a study of 8 volunteers suffering from constipation, daily consumption for 15 days of a normal diet supplemented with artichokes (180 g) enriched with 20 billions of *Lactobacillus paracasei* resulted in marked reduction in abdominal distension and feeling of incomplete evacuation (Valerio et al. 2010). The gut of all volunteers was found to be colonized by the probiotic strain after 15 days feeding. No significant differences in the microbiological counts throughout the experimental period were registered, whereas a significant increase of butyric and valeric acids with a concomitant decrease of lactic acid was registered. At the same time, the faecal beta-glucuronidase activity was significantly reduced.

In a randomized, double-blind, controlled, crossover study of 20 constipated patients, eighty

percent of patients preferred probiotic (*Lactobacillus paracasei*)-enriched artichokes which generated a positive effect compared to ordinary ones (Riezzo et al. 2012). Satisfactory relief of symptoms was significantly higher during the probiotic-enriched artichoke period. The Gastrointestinal Symptom Rating Scale (GSRS) constipation score was significantly lower in the probiotic group compared with the baseline. As for short-chain fatty acid (SCFA) production in faecal samples, propionic acid was significantly higher in the probiotic group compared with baseline.

Antiinflammatory Activity

Oral administration of a 10 % infusion (dry plant) or 20 % (fresh plant) corresponding to 1 or 2 g/kg of *Cynara scolymus* was found to have analgesic and/or antiinflammatory activities in mice (Ruppelt et al. 1991). Aqueous and ethanol artichoke extracts were found to inhibit basal and inflammatory mediators (TNF α and LPS) and ox-LDL stimulated reactive oxygen species (ROS) production in endothelial cells and monocytes in dose-dependent manner (Zapolska-Downar et al. 2002). In endothelial cells, the ethanol extract (50 μ g/ml) reduced ox-LDL-induced intracellular ROS production by 60 % while aqueous extract (50 μ g/ml) by 43 %. The ethanol extract (50 μ g/ml) reduced ox-LDL-induced intracellular ROS production in monocytes by 76 %. Effective concentrations (25–100 μ g/ml) were well below the cytotoxic levels of the extracts which started at 1 mg/ml as assessed by LDH leakage and trypan blue exclusion. The results demonstrated artichoke extracts to have marked protective properties against oxidative stress induced by inflammatory mediators and ox-LDL in cultured endothelial cells and monocytes. Flavonoids apigenin, luteolin, apigenin-7-glucoside, luteolin-7-glucoside, apigenin-7-rutinoside, luteolin-7-rutinoside and cynarin from *C. cardunculus* inhibited 12-lipoxygenase activity particularly at pH 9. The highest inhibitory activity was observed for apigenin and luteolin. Lipoxygenase inhibition

activity was positively correlated with antioxidant activity ($R^2=0.81$).

Antispasmodic Activity

Of six Brazilian medicinal plants evaluated, only the methanol extracts of *Calophyllum brasiliense* and *Cynara scolymus* showed probable antispasmodic activity (Emendörfer et al. 2005b). Both plant extracts exhibited significant inhibitory activity for the contractile response elicited by acetylcholine on guinea pig ileum and on rat duodenum in a noncompetitive and concentration-dependent manner. The results confirmed and justified their use in folk medicine for the treatment of intestinal disorders. The dichloromethane fraction of *C. scolymus* exhibited antispasmodic effect against acetylcholine-induced contractions of guinea pig ileum (Emendörfer et al. 2005a). It showed the most promising biological effects, with an IC₅₀ of 0.93 (0.49–1.77) mg/ml. Its main active component, the sesquiterpene lactone cynaropicrin, exhibited potent activity, with IC₅₀ of 0.065 (0.049–0.086) mg/ml, being about 14-fold more active than dichloromethane fraction and having similar potency to that of papaverine, a well-known antispasmodic agent. The results confirmed the popular use of artichoke for the treatment of gastrointestinal disturbances.

Antiulcerogenic Activity

Oral administration of artichoke leaf extract dose dependently prevented absolute ethanol-induced gastric mucosal injury at 125–500 mg/kg or restraint plus water immersion stress-induced gastric mucosal injury at 1,000–2,000 mg/kg in rats (Ishida et al. 2010). Cynaropicrin, a component of artichoke, prevented ethanol-induced gastric mucosal injury at 5 mg/kg, p.o. and stress-induced mucosal injury at 20 mg/kg, p.o. However, dextrin and chlorogenic acid at doses contained in the leaf extract were ineffective in both models. When artichoke leaf extract (500–2,000 mg/kg) was given orally to normal rats, it dose dependently increased gastric mucus

content. Further, it (125–500 mg/kg, p.o.) dose dependently prevented the decrease in gastric mucus content by absolute ethanol. On basal gastric acid secretion in rats, artichoke leaf extract (500–2,000 mg/kg, p.o.) dose dependently increased the volume of gastric juice in normal rats. However, it was ineffective in decreasing basal gastric acid secretion in normal rats. These results indicated that artichoke leaf extract was effective against acute gastritis and its beneficial effect was due to that of cynaropicrin. The artichoke flower-head scale extracts (200 and 400 mg/kg) significantly reduced the ulcer index (55.33 % and 72.14 % inhibition, respectively) (Nassar et al. 2013). Histopathological examination of the rat stomach found that artichoke induced an increase in gastric mucus production, reduction of the depth and severity of mucosal lesions. Artichoke dose dependently reduced the elevated ethanol gastric MDA, GSH levels and CAT activity. The results suggested that artichoke flower-head scales possessed potential antiulcer activity.

Antiphotaging Activity

Studies showed cynaropicrin, a sesquiterpene lactone from artichoke, to be an effective anti-photaging agent that acted by inhibiting nuclear factor kappa (NF- κ B)-mediated transactivation of basic fibroblast growth factor (bFGF) and matrix metalloprotease-1 (MMP-1) (Tanaka et al. 2013). NF- κ B is activated by stimulation such as ultraviolet rays and inflammatory cytokines and induces the expression of various genes such as those of bFGF and MMP-1. Further, it was confirmed that in an in-vivo mouse model, cynaropicrin prevented skin photaging processes leading to the hyperproliferation of keratinocytes and melanocytes.

Studies by Moglia et al. (2008) found that exposure of artichoke plants of different genotypes to UV-C radiation consistently increased the levels of dicaffeoylquinic acids in all genotypes, whereas the effect on compounds from the same biosynthetic pathway, for example, chlorogenic acid and luteolin-7-glucoside, was much

less pronounced. The major phenolic compounds identified in globe artichoke leaves were four isomers of dicaffeoylquinic acid, three isomers of caffeoylquinic acid, and the flavone luteolin 7-glucoside. On the basis of these results, a role of dicaffeoylquinic acids in UV protection in globe artichoke was hypothesized.

Cardiovascular Activities

In EA.hy 926 cells, a cell line derived from human umbilical vein endothelial cells (HUVECs), an artichoke leaf extract (ALE) increased the activity of the human endothelial nitric-oxide synthase (eNOS) promoter (determined by luciferase reporter gene assay) (Li et al. 2004). An organic subfraction from the leaf extract was more potent in this respect than the crude extract, whereas an aqueous subfraction of the extract was without effect. In organ chamber experiments, ex-vivo incubation (18 hours) of rat aortic rings with the organic subfraction enhanced the NO-mediated vasodilator response to acetylcholine, indicating that the upregulated eNOS remained functional. Caffeoylquinic acids and flavonoids were identified as the two major groups of constituents of the extract. The flavonoids luteolin and cynaroside increased eNOS promoter activity and eNOS mRNA expression, whereas the caffeoylquinic acids cynarin and chlorogenic acid were without effect. The results suggested that in addition to the lipid-lowering and antioxidant properties of artichoke, an increase in eNOS gene transcription may also contribute to its beneficial cardiovascular (anti-thrombotic and anti-atherosclerotic) profile. Studies by Juzyszyn et al. (2008b) suggested that artichoke extracts could act as endothelium protecting agents. Preincubation of cultured human umbilical endothelial cells (HUVECs) with the artichoke extract at concentrations of 25–100 μ g/ml for 24 hours abolished ROS (reactive oxygen species) generation induced by LPS and oxLDL. Also potent, concentration-dependent reductive properties of the artichoke extract were demonstrated by the reduction kinetics of cytochrome c in reference to ascorbate.

Hypotensive Activity

In a randomized, placebo-controlled trial of patients with mild hypertension (systolic blood pressure [SBP]/diastolic blood pressure [DBP], 140–159/90–99 mmHg), 12 weeks consumption of concentrated artichoke leaf juice significantly reduced SPB compared with the baseline data, and DBP was significantly lower from the baseline as compared with the placebo group (Roghani-Dehkordi and Kamkhah 2009). It was concluded that the use of artichoke juice concentrate may have a blood pressure-lowering effect in mild hypertension.

Genotoxicity/Antigenotoxicity Activities

In the evaluation for genotoxicity, all doses of artichoke leaf extract (0.62, 1.25, 2.5 and 5.0 mg/ml) used led to a significant increase in the frequency of DNA damage, after exposure for 1 and 24 hours (Jacociunas et al. 2012a). In the antigenotoxicity experiments, the leaf extract reduced the frequency of DNA damage induced by the alkylating agent ethyl methane-sulfonate in the simultaneous treatment only. However, the lowest dose was more protective than higher concentrations. Flavonoids and phenolic compounds in *C. scolymus* were suggested to be probably responsible for its genotoxic and antigenotoxic effects. Results of a study employing the cytokinesis-block micronucleus cytome assay in Chinese hamster ovary cells suggested that high concentrations of artichoke leaf extract could pose a risk associated to its consumption (Jacociunas et al. 2012b). All concentrations of the extract produced increments in micronuclei frequencies in both exposure times, when compared to the negative control. No significant differences were observed in the nuclear division cytotoxicity index (NDCI), reflecting the absence of cytotoxic effects attributable to the leaf extract.

Genotoxic and mutagenic studies in mice showed that artichoke leaf aqueous extracts did not increase micronuclei in peripheral blood cells in the micronuclei test (Zan et al. 2013).

Compared to the control group, a significant increase in comet assay values was observed only in bone marrow of group treated with 2,000 mg/kg, the highest dose tested, indicating that artichoke tea should be consumed with moderation. The results indicated that artichoke lack of mutagenicity in vivo and had low genotoxicity.

Chemoprotective Activity

The study by Gurel et al. (2007) found that artichoke extract supplementation exerted a protective effect on gonads of cadmium-treated rats; in particular it exhibited a clear protective effect against cadmium-induced testicular damage and lowered nitric oxide production to the same level of that in the control groups.

Hypouricemic Activity

Studies showed that an aqueous artichoke leaf extract and some of its components, caffeic acid derivatives and flavones, exerted xanthine oxidase inhibitory effects in vitro but a hypouricemic activity could not be confirmed after acute oral treatment in potassium oxonate-treated rats (Sarawek et al. 2008). After intraperitoneal injection of luteolin a decrease in uric acid levels was detected suggesting that the hypouricemic effects of luteolin were due to its original form rather than its metabolites produced by the gut flora.

Mitochondrial Respiratory Chain (MRC) Activity

In-vitro studies showed that artichoke extract in the range of 0.68–2.72 µg/ml demonstrated potent and concentration-dependent mitochondrial respiratory chain (MRC) inhibitory activity in isolated rat liver mitochondria (Juzyszyn et al. 2010). Concentrations ≥ 5.4 µg/ml entirely inhibited MRC activity. The succinate oxidase system (MRC complexes II–IV) was the most potently inhibited. Inhibition of the succinate oxidase system was competitive ($K(i)=0.23$ µg/ml),

whereas isolated cytochrome oxidase was inhibited noncompetitively ($K(i)=126\text{ }\mu\text{g/ml}$). The results suggested that the health-beneficial effects of artichoke extracts may partly rely on the effects of their active compounds on the activity of the mitochondrial respiratory chain system.

Urinary Excretion of Nicotine Activity

Studies showed that co-administration of nanozeolites and artichoke leaf extract had a synergistic effect on increasing the urinary excretion of nicotine in rats (Malekshah et al. 2012). Artichoke leaf extract caused increase in urinary excretion of nicotine in longer post-administration times.

Alcohol Hangover Ameriolation

In a randomized double-blind, placebo-controlled, crossover trial of 15 healthy adult volunteers between 18 and 65 years, administration of 3 capsules of commercially available standardized artichoke extract immediately before and after alcohol exposure was found not effective in preventing the signs and symptoms of alcohol-induced hangover (Pittler et al. 2003). None of the outcome measures differed significantly between interventions. Adverse events were rare and were mild and transient.

Pharmacokinetics Studies

Six metabolites derived from artichoke leaf extract, namely, hydroxycinnamates—caffeic acid, dihydrocaffeic acid, ferulic (FA), dihydroferulic acid, and isoferulic acid and the flavonoid luteolin were detected in human plasma by high-performance liquid chromatography-coulometric-array detection (Wittemer and Veit 2003). After oral administration of Artichoke leaf extracts to 14 healthy human volunteers, none of the genuine target extract constituents could be detected in the plasma or urine (Wittemer et al. 2005). However, caffeic acid (CA), its methylated derivatives ferulic acid (FA) and isoferulic acid (IFA), and the

hydrogenation products dihydrocaffeic acid (DHCA) and dihydroferulic acid (DHFA) were identified as metabolites derived from caffeoylquinic acids. Except for DHFA, all of these compounds were present as sulfates or glucuronides. Peak plasma concentrations of total CA, FA and IFA were reached within 1 hour and declined over 24 hours showing almost biphasic profiles. In contrast maximum concentrations for total DHCA and DHFA were observed only after 6–7 hours, indicating two different metabolic pathways for caffeoylquinic acids. Luteolin administered as glucoside was recovered from plasma and urine only as sulfate or glucuronide but neither in form of genuine glucosides nor as free luteolin. Peak plasma concentrations were reached rapidly within 0.5 hour. Studies by Azzini et al. (2007) confirmed the bioavailability of metabolites of hydroxycinnamic acids after ingestion of cooked edible *Cynara scolymus* (cultivar Violetto di Provenza). They found a plasma maximum concentration of 6.4 ng/ml for chlorogenic acid after 1 hour and its disappearance within 2 hours. Peak plasma concentrations of 19.5 ng/ml for total caffeic acid were reached within 1 hour, while ferulic acid plasma concentrations showed a biphasic profile with 6.4 and 8.4 ng/ml within 1 hour and after 8 hours respectively. A significant increase of dihydrocaffeic acid and dihydroferulic acid total levels after 8 hours was observed. No circulating plasma levels of luteolin and apigenin were detected. In another study, the limits of detection in rat plasma for cynarin and luteolin were 0.75 and 0.1 $\mu\text{g/cm}^3$ and the limits of quantification were 2.25 and 0.2 $\mu\text{g/cm}^3$, respectively (Kulza et al. 2012b). Recovery was 67 % for cynarin and 96 % for luteolin.

Milk Clotting Activity

Aspartic proteinases from flowers of *Cynara cardunculus* have been extensively studied and long used as coagulants in the manufacture of several traditional Spanish and Portuguese cheeses (Sidrach et al. 2005) and as an alternative to calf stomach rennet (Chazarra et al. 2007). Two aspartic proteinases were isolated from stigmas

of the cardoon *Cynara cardunculus* and named cardosin A and cardosin B (Veríssimo et al. 1996). Cardosin A showed two bands with apparent molecular masses of 31,000 and 15,000 Da, whereas the chains of cardosin B showed bands of 34,000 and 14,000 Da. The partial amino acid sequences of the two cardosins revealed that they were similar but not identical and that they differed from the previously reported cardoon proteinases named cynarases, which were assumed to be derived from a common precursor. Both cardosins were active at low pH and were inhibited by pepstatin. A heterodimeric milk-clotting proteinase consisting of 30- and 15-kDa subunits was isolated from artichoke flowers (Llorente et al. 2004). The amino terminal sequence of the 30-kDa chain proved to be identical to the larger cardosin A subunit (an endopeptidase). Maximum proteolytic activity was recorded at pH 5.0 and was inhibited by pepstatin. The crude protease extract was found to be potentially useful for cheese production. According to Sidrach et al. (2005) cardosins and cynarases are similar and are called differently by various authors. Three endopeptidases, cynarases A, B and C, with milk-clotting properties were purified from the stigma of globe artichoke (Sidrach et al. 2005). All three proteinases were found to be glycoproteins and to compose of one large and one small subunits. Cynarase A was found to be an aspartic proteinase and expressed maximum activity at pH 5 and 70 °C. The results indicated artichoke extract could also be used in the milk industry in the same way as the extract obtained from the flower of cardoon *C. cardunculus*. Milk coagulation activity of artichoke flower extract was highly dependent upon milk pH and temperature (Chazarra et al. 2007). The rennet strength (RS) of this extract was found to increase hyperbolically with increasing calcium concentrations. The crude extract was found to contain cynarases A, B and C. Purification led to a decrease in the specific coagulant activity relative to that of the crude extract in the case of cynarases A and C, whereas cynarase B increased its specific clotting activity. Also cynarases A and C showed a slight increase in specific peptidase activity relative to the initial extract; the specific peptidase activity

of cynarase B was much higher. Crude water extracts of dried and fresh cardoon flowers had high yield of rennet-like proteases but low protein content and proteolytic activity, whereas citric acid extracts had low yield but high protein content and proteolytic activity (Chen et al. 2003). Fresh flower extracts gave higher yield and proteolytic activity but lower protein content in comparison with dried flower extracts. Irrespective of extraction method, all extracts had higher proteolytic activity against ovine whole and kappa-caseins compared to their bovine counterparts, showing optimal activity at 37 °C and pH 6.0. Separation of purified extracts yielded three active fractions, each with two subunits with molecular masses of 15.5 and 33.1 kDa, respectively.

Toxicity Studies

Studies in Bulgaria found that 75 day administration of artichoke preparation at doses 35.70 and 150 mg/kg to sexually mature male white Wistar rats caused no significant changes in the structure of the semen of white rats, established at both cellular and subcellular level (Ilieva et al. 1994). There was no evidence that the artichoke preparation was injurious or stimulating to the male gonads.

Allergic Problems

Some individuals handling artichoke have been reported to develop contact hand dermatitis (Meding 1983) and contact urticaria syndrome on exposure to globe artichoke, a type-1 allergen (Quirce et al. 1996). Case studies of 2 vegetable warehouse workers who developed occupational rhinitis and bronchial asthma by sensitization to artichoke were presented (Miralles et al. 2003). In both patients, results of skin prick tests to artichoke were positive. Levels of specific IgE for artichoke were 0.68 kU/l in patient 1 and 2.14 kU/l in patient 2. Nasal challenge with artichoke extract triggered a peak nasal inspiratory flow decrease of 81 and 85 % in patient 1 and patient 2, respectively.

A woman with a past history of allergy to artichoke presented with two episodes of immediate allergic reactions, one of which was a severe anaphylactic shock after eating two types of health foods containing inulin (Franck et al. 2005). Specific IgEs to artichoke, to yoghurt F, and to a heated BSA+inulin product were identified. Dot-blot inhibition techniques confirmed the anti-inulin specificity of specific IgE.

Traditional Medicinal Uses

Artichoke has a long history of traditional use in herbal medicine dating back to the sixteenth century. The leaves are anticholesterolemic, anti-rheumatic, cholagogue, digestive, diuretic, hypoglycaemic and lithontripic (Lust; Chiej 1984; Bown 1995; Chevallier 1996). They are used in cases of jaundice, oedema (fluid retention), hepatitis, arteriosclerosis, urinary gallstones, and early stages of late-onset diabetes. Artichoke is also used to stimulate digestive juices and lower cholesterol (Grammelis et al. 2008). Globe artichoke leaves extracts have long been used in folk medicine for their cholaretic and hepatoprotective activities (Speroni et al. 2003), for treatment of hepatitis, obesity, hyperlipidaemia and dyspeptic disorders (Nassar et al. 2013). Artichoke tinctures containing caffeoylquinic acids and flavones are largely used in hepatic disorders (Bilia et al. 2002). In Poland, artichoke with multiple therapeutic properties and practically no side effects is recommended as herbal medicine not only in disorders of the liver but also in the prevention of atherosclerosis and hyperlipidaemia or dyspeptic disorders (Horoszkiewicz et al. 2012; Kulza et al. 2012a).

Other Uses

Globe artichoke/cardoon is also an attractive plant, valued as an ornamental for its bright floral display, and sometimes grown in herbaceous borders and beds for its bold foliage and large purple/blue flower heads. The flowers are used as cut flowers for flower arrangements. The flowers

attract bees, the principal pollinators. The plant also improves soil characteristics and prevents erosion.

C. cardunculus (cardoon) also known as cynara in the field of energy crops can be cultivated as an energy crop producing biomass and be used for biodiesel production and other industrial purposes (Fernández and Curt 2004; Fernández et al. 2006). Studies have reported on the feasibility of cynara, for biomass production as an energy crop in several Mediterranean countries (Encinar et al. 1999; Fernández and Curt 2004; Fernández et al. 2006; Grammelis et al. 2008; Ierna and Mauromicale 2010; Gominho et al. 2011). Studies showed that on average for the 14 genotypes of *C. cardunculus* L., five cultivated cardoons and nine wild cardoons grown in a Mediterranean environment, a 3-year cumulative above-ground biomass of 47.4 t/ha DM, the 6.3 % of which was grain (Raccuia and Melilli 2007). Two types of products can be harvested: lignocellulosic biomass and oil seeds (Fernández et al. 2006). Cynara lignocellulosic biomass is a solid biofuel that can be used directly for heating or for electric power generation. The cynara oil exhibits a similar fatty acid profile to the common sunflower oil and has been successfully experimented for the production of biodiesel by a process of transesterification (Encinar et al. 1999). The biodiesel from cynara has similar properties to those of biodiesel 2.

Cynara oil was reported to have the following properties: refractive index 1.47, iodine index 125, saponification index 186.6, peroxide value 4.77 meq O₂/kg, unsaponifiable matter 10.7 %, fatty acids—palmitic acid 10.7 %, stearic acid 3.7 %, oleic acid 25 %, linoleic acid 59.7 %, fuel properties—density 0.924, HCV 32.00 MJ/kg, viscosity 40° 31.3 mm/s, cetane number 51.4, flash point 350 °C (Fernández and Curt 2004). Studies by Grammelis et al. (2008) found that *Cynara cardunculus* (cardoon), under certain circumstances, can be used as a solid biofuel of acceptable quality. It is now considered the most important and promising sources for solid biofuel production in Greece. Thermogravimetric analysis showed that the decomposition process of cardoon followed the degradation of other

lignocellulosic fuels, meeting high burnout rates. Considering its high adaptability to the xerothermic conditions of southern Europe and its high biomass productivity on most soils with modest or without any inputs of irrigation and agrochemicals, *C. cardunculus* may produce the cheapest biofuel compared to all other bioenergy crops known.

In addition to the energy applications of the crop, other alternative applications include green forage for ruminants, paper pulp production, cheese production and pharmacological active compounds extraction. Artichoke seed oil may be used for making soap, hair shampoo, alkyd resin and shoe polish (Miceli and De Leo 1996). *C. cardunculus* seed presscake has potential to be used as fertilizer or animal feed (Curt et al. 2002; Fernández et al. 2006).

A study showed that lambs fed a diet supplemented with artichoke bracts (550 g/day for 133 days), produced lambs with a lower content in monounsaturated fatty acids in the meats and a higher one in saturated fatty acids in the subcutaneous fat. Also fat deposits had a higher percentage of w3-series fatty acids (Marsico et al. 1999). Studies showed that the silage by-product after industrial processing of artichoke (*Cynara scolymus*) could be used as ruminant feed after 12 days of ensilage (Meneses et al. 2007). Cajarville et al. (2000) found that *C. cardunculus* (cardo) seed inclusion in the ruminant diets up to a 25 % had no effect on rumen fermentation patterns or on ruminal fibrolytic activity, in spite of the high content of fat rich in unsaturated fatty acids (85.5 % of total fatty acids) of the seed. Crude protein (CP), ether extract (EE) and neutral detergent fibre (NDF) contents of whole cardoon seed were 225, 250 and 338 g/kg DM, respectively. Rumen dry matter degradability of whole seed was 56.8 %, while CP degradability was 82.9 %. Digestibility coefficients (%) were 83.8 for CP, 82.8 for EE, 20.3 for NDF, 56.1 for organic matter, and 59.2 for energy.

Studies reported that *Cynara cardunculus* has potential as a new fibre crop for pulp and paper production (Gominho et al. 2001). The plant stalks were found to have 7.7 % ash, 14.6 % extractives,

17.0 % lignin and 53.0 % polysaccharides, mainly cellulose and xylans. The pith had more lignin than the depithed stalk. Depithing of the stalks had a positive impact on pulp yield, chemical consumption and on the pulp strength properties. Studies found the hairs and pappi from *Cynara cardunculus* capitula to be suitable material for paper pulp production (Gominho et al. 2009). Pulps could be produced using a conventional kraft process with high yields and low residual lignin. Hairs and pappi are filamentous structures made up of longitudinally aligned fibre cells, without intercellular voids or pitting, and were found to have low content of ash (1.9 and 1.1 %, respectively), extractives (5.4 and 6.0 %) and lignin (10.6 and 17.8 %), and high content of holocellulose (77.5 and 72.8 %) and α -cellulose (55.2 and 46.8 %). The utilization of hairs and pappi may strengthen the differentiated use of biomass fractions of the *Cynara* plant and its potential as a bioenergy crop.

A statistically significant protective effect of 5 % total water extract of artichoke on humoral immune response (increase of haemagglutination-inhibition antibody titer), on relative organ weight, as well as on pathomorphological, haematological and biochemical changes induced by ochratoxin A in broiler chicks was established (Stoev et al. 2000). Subsequent studies found a protective effect of artichoke aqueous extract as a feed additive against the suppressive effect of ochratoxin A on egg production of laying hens (Stoev 2010). A significant protection was found against the decrease of the weight or the quantity of eggs as well as against the delay of the beginning of the laying period of chicks, both of which were provoked by ochratoxin A.

Comments

Leading producers of artichokes in the world are Italy 474, 550 t; Egypt 202,458 t; Spain 182,111 t; Peru 150,417 t; Argentina 100,891 t; China 75,000 t; France 52,032 t; Morocco 44,187 t; United States 43,640 t; and Chile 41,694 t (FAO 2012).

Common/English Name

Red Dahlia

Vernacular Names

Indonesia: Bunga Kana

Mexico: Cohuanenepilli (Aztec), Cohuanenepilli (Nahuatl), Kachana

Polish: Dalia Szkarłatna

Swedish: Scharlakansdahlia

Origin/Distribution

The species is native to central Mexico and has been introduced and grown in other subtropical and tropical areas.

Agroecology

The plant thrives in a sunny position in well-drained, moderately moist, fertile, deep, loamy soils. The plant needs protection from cold winds and is sensitive to frosts.

Edible Plant Parts and Uses

Flowers can be used in salads, cream, cheese and dip; some recipes include a dahlia dip, sundried tomato and dahlia bread (Hedrick 1972; Roberts 2000). In Mexico, boiled tubers of kachana were eaten (Laferriere et al. 1991). Tubers of *Dahlia* spp. were widely used in pre-Spanish Mexico and are very high in inulin and fructose (Whitley 1985).

Botany

A deciduous, branched, perennial herb, to 2 m high with large underground tuberous roots. Leaves opposite or alternate, simple to pinnate with 3–5 elliptic, serrate-dentate leaflets, glabrous (Plates 1 and 2). Inflorescence of solitary, long-pedunculate, involucre, radiate, stellate capitulum. Involucral bracts in 2 series, the outer series rather fleshy and foliaceous, inner series membranous. The central portion of the capitulum is comprised of florets with tubular bisexual, tubular, short 5-lobed, yellow corollas. The outer, more showy portion of the capitulum is comprised of a single row of ray florets with a single, flat ligulate corolla, yellow, red, orange, orange-red or bicoloured in some cultivars (Plates 1 and 2). Achenes dorsally compressed, pappus absent.

Nutritive/Medicinal Properties

Proximate composition of *D. coccinea* tuber (% moisture free basis) was reported as energy 258 kcal, protein 16.39 %, carbohydrate 47.81 %, lipids 0.15 %, fibre 31.28 % and ash 4.37 %, Fe 41 ppm, Cu 9 ppm, Ca3756 ppm and Mg 1,513 ppm (Laferriere et al. 1991).

Dahlia flower colour appeared to be exclusively based on the accumulation of flavonoids and biochemically related anthochlors (chalcones, aurones) (Harborne 1967; Giannasi 1975; Halbwirth et al. 2008). Malonic acid also occurred bound to non-anthocyanic glycosides; butein

Plate 1 *Dahlia coccinea* flower

Plate 2 Leaves and bicoloured dahlia flowers

(2'4',3,4-tetrahydroxyxhalcone) 4'-O-glucoside and 4'-O-sophoroside existed as their respective malonate esters in both *D. coccinea* and *D. variabilis* (Harborne et al. 1990).

Polyacetylene compounds were found in the tubers and aerial plant parts of *D. coccinea* (Lam et al. 1968). Polyacetylene compounds with an ene-diynediene chromophore were found abundantly in *D. pinnata*, whereas at most traces of compounds with this chromophore were detected in *D. coccinea* (Bendixen et al. 1969). Three *Dahlia pinnata* varieties were found to contain 1-phenylhept-5-ene-1,3-diyne and 1-phenyl-hepta-1,3,5-triyne and derivatives which had previously been found in one *Dahlia coccinea* variety and in a horticultural form (Lam 1973). Nineteen polyacetylenes were detected in *Dahlia coccinea* Cav. var. *coccinea* comprising eight C₁₃, eight C₁₄ and three C₁₇ compounds (Chin et al. 1970). Five of them were previously unknown, including C14-tetrahydropyranyl compounds. Twenty-six polyacetylenes of known structures 1-phenylhept-5-ene-1,3-diyne and 1-phenyl-hepta-1,3,5-triyne and derivatives together with cosmene and eugenol were isolated and characterized from roots, leaves and flowers of *Dahlia australis*, one *D. coccinea* variety, and two varieties of *D. sherffii* (Lam et al. 1991).

According to Christensen (2010) polyacetylenes appear to be an important group of nutraceuticals in vegetable foods that are obvious targets for the development of healthier foods and food products. The beneficial effects of most bioactive polyacetylenes from higher plants occur at nontoxic concentrations. However, some polyacetylenes are known to be potent skin sensitizers, and to be neurotoxic in high concentrations, but are also highly bioactive compounds with potential health-promoting properties.

Tubers of *D. coccinea* were reported to have antibiotic and antiatherogenic properties and to act as central nervous system depressants (Whitley 1985; Jiu 1966). The Aztecs used the petals of the dahlia, as well as its tuber in skin treatments for rashes, infected grazes and cracks in the skin. The roots of the plant were found to contain antibiotic compounds which were most plentiful in the skin of the tuber. In the past, the petals were crushed, mashed up and used to soothe insect bites or stings.

Other Uses

The dahlia flower was a solar symbol worn by Montezuma and nobles (Whitley 1985). Dahlia is widely planted as border plants or in pots. The flowers are used as cut flowers.

Comments

Most commonly grown dahlias are hybrids of *D. pinnata* and *D. coccinea*. Dahlias are propagated from seeds, division of tubers or cuttings.

Origin/Distribution

The species is native to Mexico and Central America to Columbia.

Agroecology

Dahlia grows best in full sun in friable, moderately moist, well-drained, fertile soils with pH 6–6.5. It thrives best in volcanic soils as found in its natural habitat in Mexico. It is frost tender and drought intolerant.

Edible Plant Parts and Uses

The flower petals are eaten in salads; the tubers are eaten as vegetables in some parts of Mexico (Uphof 1968; Hedrick 1972; Facciola 1990; Roberts 2000). A sweet extract of the tuber, called ‘dacopa’, is used as a beverage or as a flavouring, mixed with hot or cold water or milk or sprinkled on ice cream. Its naturally sweet mel-low taste is said to combine the characteristics of coffee, tea and chocolate. Some culinary recipes of Dahlia flowers include Mexican mealie and chili dish, cream cheese and Dahlia dip and sun-dried tomato and Dahlia bread (Roberts 2000).

The tubers are rich in reserve carbohydrate, inulin, a fructan, which is composed of $\beta(2 \rightarrow 1)$ linked D-fructose residues and provides a good natural source for the production of fructose syrups that are widely used in the food industry (Mino et al. 1985; Mangunwidjaja et al. 2002). Fructose is an interesting sweetener because of its high sweetening power. Fructose is claimed to be less cariogenic than other sugars and to be more suitable for diabetics since it is insulin nondependent (Barker and Petch 1985). Purified inulin from Dahlia tubers was partially hydrolyzed to form fructooligosaccharides by using citric or phosphoric acids (pH, 2.0–2.5) as mild acid catalysts (Fontana et al. 2011). These whole hydrolysates can be advantageously added as nutraceuticals to carbonated beverages and acidic foods, such as soft drinks and yogurts.

The common garden variety Dahlia was once an important root crop and medicinal plant among the pre-Columbian Indians of Central Mexico, Yucatan and Guatemala. Its roots were valued both for the nutritious inulin stored inside them and for the antibiotic compounds concentrated in the skin of the tubers (Whitley 1985).

Botany

A deciduous, branched, perennial herb, to 1.8 m high with large subterraneous tuberous roots. Internode of stems hollow, leaves opposite or whorled, simple to 2-pinnatisect with 3–5 elliptic, serrated leaflets, glabrous and glaucous beneath (Plates 2 and 3). Inflorescence of solitary or few, long-pedunculate, involucrate, radiate capitulum, 10–20 cm across. Involucral bracts in 2 series, the outer series rather fleshy and foliaceous, inner series membranous and shortly united at the base, receptacle scaly. Disc florets bisexual, actinomorphic, tubular, 5-lobed sometimes mostly or all replaced by ray florets as in cultivated hybrid progeny. Ray florets, several marginal rows, zygomorphic, female and fertile, or neuter, the ligules patent with incurved or recurved margins, purple in wild plants and white, yellow, pink, red or purple in horticultural improved plants (Plates 1, 2 and 3). Achenes dorsally compressed, pappus absent or shortly bidentate.

Plate 1 Red-flowered pinnate Dahlia

Plate 2 Pale lilac-flowered pinnate Dahlia and leaves

Plate 3 Yellow-flowered pinnate Dahlia

Nutritive/Medicinal Properties

Pigments responsible for the diverse range of floret colours ivory, yellow, pink, red, purple and red-black in Dahlias had been reported to include flavonoids, mainly anthocyanins, butein, and flavones and their derivatives (Bate-Smith and Swain 1953; Nordstrom and Swain 1953, 1956, 1958; Bate-Smith et al. 1955; Harborne et al. 1990; Yamaguchi et al. 1999). Pigments were

first studied in Dahlia in the early 1950s when the presence of anthocyanins, flavones, flavonols, chalcones and aurones were elaborately described in Dahlia species (Bate-Smith and Swain 1953; Nordstrom and Swain 1953, 1956, 1958; Bate-Smith et al. 1955). Bate-Smith and Swain (1953) isolated 2,4,4'-trihydroxychalcone from yellow varieties of *Dahlia variabilis*. Apart from anthocyanins and 6'-deoxychalcones, flavones and flavonols could accumulate in Dahlia flowers (Nordstrom and Swain 1953, 1956, 1958). Blue-coloured flower of *D. variabilis* var. Dandy was found to contain apigenin, its 4- and 7-monoglucosides and 7-rhamnoglucoside, luteolin 5-mono-glucoside and 7-diglucoside, cyanidin arabinoglucoside, and a few minor compounds (Nordstrom and Swain 1953). Flavonoid glycosides extracted from the yellow petals of two yellow Dahlias included 3',4',6-trihydroxyaurone in var. 'Pius IX'. The 6-mono- and diglucosides of this compound were found in var. 'Coton' together with the 7-mono- and diglucosides of liquiritigenin, the 4-monoglucosides of both butein and 2,4,4'-trihydroxychalcone, and the 4-diglucoside of the last named compound (Nordström and Swain 1956). The ivory Dahlia 'Helly Boudewyn' contained the same flavone glycosides as those which had previously been found in the blue Dahlia 'Dandy', and naringenin and eriodictyol were found in a white Dahlia 'Clare White' (Nordström and Swain 1958). Polyacetylene compounds with an ene-diyne chromophore were found abundantly in *D. pinnata*, whereas most traces of compounds with this chromophore were detected in *D. coccinea* (Bendixen et al. 1969). Three *Dahlia pinnata* varieties were found to contain 1-phenylhept-5-ene-1,3-diyne and 1-phenyl-hepta-1,3,5-triene and derivatives which had previously been found in one *Dahlia coccinea* variety and in a horticultural form (Lam 1973).

Kaufmann and El Baya (1970) and Harborne et al. (1990) found 6'-deoxychalcones (derivatives of butein and isoliquiritigenin) and the corresponding 4-deoxyaurones (derivatives of sulfuretin) to be the chemical base of yellow flower colour in *D. variabilis*; these were mixed with anthocyanins (derivatives of pelargonidin

and cyanidin) in orange and red forms. The yellow pigments, the 4'-malonylsophoroside and 4'-malonylglucoside of butein, were found in the petals of *Dahlia variabilis* and *D. coccinea*, co-occurring with malonylated anthocyanins in these flowers (Harborne et al. 1990). A screening of more than 200 *Dahlia* cultivars revealed that the different red tones were based on the same set of anthocyanins and that variation in the anthocyanin concentration, the modification pattern of the core structures, and probably also pH were responsible for the formation of different hues (Halbwirth et al. 2008). Orange, rose and lilac cultivars frequently showed lower anthocyanin contents than red and magenta cultivars. Rose and lilac cultivars appeared to be primarily based on a lower chalcone synthase activity (Halbwirth et al. 2008). Thus, *Dahlia* flower colour appeared to be exclusively based on the accumulation of flavonoids and biochemically related anthochlors (chalcones, aurones) (Harborne 1967; Giannasi 1975; Halbwirth et al. 2008). Recently, Thill et al. (2012) reported that *Dahlia* resulted from the accumulation of red anthocyanins, yellow anthochlors (6'-deoxychalcones and 4-deoxyaurones) and colourless flavones and flavonols, acting as copigments.

Garden Dahlias (*Dahlia variabilis*) are autoallootoploids with redundant genes producing wide colour variations in flowers (Ohno et al. 2011b). Genetically, four elements were believed to explain the inheritance of ray floret colours in *Dahlia*: A (pale anthocyanin), B (deep anthocyanin), I (flavone), and Y (yellow) (Lawrence 1931; Lawrence and Scott-Honcrieff 1935; Bate-Smith et al. 1955; Broertjes and Ballego 1967). Yellow and white cultivars appeared not to accumulate anthocyanins due to a bottleneck or blockage of the anthocyanin pathway. For yellow cultivars, this was most frequently observed at the levels of both flavanone 3-hydroxylase (FHT, synonym F3H) and dihydroflavonol 4-reductase (DFR) (Halbwirth et al. 2008). Fischer et al. (1988) purified and characterized (+) dihydroflavonol (3-hydroxyflavanone) 4-reductase from flowers of *Dahlia variabilis*. Cyanic flowers of *Dahlia variabilis* were found to contain monomalonylated anthocyanins, 3-(6''-malonylglucoside)-5-glucosides of

pelargonidin and cyanidin, and dimalonylated anthocyanins, 3,5-di(malonylglucoside)s of pelargonidin and cyanidin, in addition to nonmalonylated 3,5-diglucosides of these anthocyanins (Yamaguchi et al. 1999). Enzyme extracts from this plant catalyzed the malonylation of anthocyanidin 3-glucoside to anthocyanidin 3-(6''-malonylglucoside), but not the 3,5-diglucoside to 3-(6''-malonylglucoside)-5-glucoside or 3,5-di(malonylglucoside). The anthocyanin 5-*O*-glucosyltransferase (SGT) was shown to catalyze glucosyl group transfer from UDP-glucose to the 5 position of anthocyanidin 3-*O*-glucoside and 3-*O*-malonylglucoside; it was purified from cyanic flowers of *Dahlia variabilis* (Ogata et al. 2001). The apparent *K_m* values for cyanidin 3-*O*-glucoside, cyanidin 3-*O*-(6''-*O*-malonyl)glucoside, and UDP-glucose were 120, 75, and 250 $\mu\text{mol/l}$, respectively. Pelargonidin 3-*O*-glucoside and malonylglucoside were also considerable substrates, but low relative activity was observed for delphinidin 3-*O*-glucoside which has yet not been found in *Dahlia* flowers. Suzuki et al. (2002) identified a cDNA coding for the 3-glucoside-specific malonyltransferase for anthocyanins, that is, malonyl-coenzyme A/anthocyanidin 3-*O*-glucoside-6''-*O*-malonyltransferase, from *Dahlia* (*Dahlia variabilis*) flowers. Schlangen et al. (2010) found that the enzyme flavonoid 3'-hydroxylase (F3'H) could catalyzed chalcone 3-hydroxylation during flavonoid synthesis in the petals of *D. variabilis*. Other enzymes involved in the regulation of anthocyanin synthesis in *Dahlia* included chalcone synthase 1 (DvCHS1), flavanone 3-hydroxylase (DvF3H), dihydroflavonol 4-reductase (DvDFR), anthocyanidin synthase (DvANS), chalcone isomerase (DvCHI) and DvCHS2 (Ohno et al. 2011a, b). A bHLH transcription factor, DvIVS, is involved in regulation of anthocyanin synthesis in *Dahlia* (*Dahlia variabilis*) (Ohno et al. 2011a).

Noguchi and Yamamoto (2006) found *Dahlia* tubers to be a good source of inulin, a soluble dietary fibre. *Dahlia* inulin was extracted and purified free from atropine, and the average purities of inulin before and after refining were 83.2 % ($n=16$) and 97.9 % ($n=8$). Inulin with a content of 95.72 % and bound glucose 4.38 % were extracted from *Dahlia* tubers (Anan'ina

et al. 2009). Inulin from Dahlia tubers (50 g% yield, dry basis; 12.5 g% yield, wet basis) can be processed to yield fructose and by-products hydroxymethylfurfural (HMF), (di)fructose anhydrides (DFA), and oligosaccharides (Haully et al. 1992). Pure nonhydrolyzed inulin was directly converted to ethanol in a simultaneous saccharification and fermentation process using *Aspergillus niger* and *Saccharomyces cerevisiae* (Ohta et al. 1993). The maximum volumetric productivities of ethanol were 6.2 and 6.0 g/l/h for chicory and Dahlia inulins, respectively. The conversion efficiency of inulin to ethanol was 83–84 % of the theoretical ethanol yield.

Inulin was reported to contain 1/3 to 1/4 of the food energy of sugar and 1/6 to 1/9 food energy from fat, which serves as the carbohydrate reserves (Franck and Leenheer 2002). Inulin is useful to replace fat and sugar; it also improves mineral absorption and is reported to possess immunomodulatory properties and to have a preventive effect against colon cancer (Franck and Leenheer 2002).

The chloroform dried leaf extract showed highest antibacterial activity against *Enterobacter aerogenes* (Bissa et al. 2011). Fresh root extract inhibited the growth of *Escherichia coli* and *E. aerogenes*; the fresh stem extracts were effective against *E. aerogenes*, while the fresh leaf and fresh flower extracts were inhibitory to *Agrobacterium tumefaciens*. The dried flower extracts exhibited antimicrobial activity against *E. coli* and *A. tumefaciens*. Rai and Acharya (1999) reported the antimycotic property of *D. pinnata* against *Fusarium oxysporum*. They found, however, that the essential oil of *Dahlia pinnata* had minimum fungitoxic activity against *F. oxysporum* and *Trichophyton mentagrophytes* (Rai and Acharya 2000).

Traditional Medicinal Uses

Tubers of *Dahlia* spp. were widely used in pre-Spanish Mexico and were found to be very high in inulin and fructose (Whitley 1985). The Aztecs used the petals of the Dahlia as well as its tuber in skin treatments for rashes, infected grazes and

cracks in the skin. The skin of the tubers was found to be rich in antibiotic compounds. In the past, the petals were crushed, mashed up, and used to relieve insect bites or stings.

Other Uses

Dahlias are attractive and popularly planted as a garden ornamental in the ground or in containers. The flowers also provide good cut flowers as Dahlia blooms profusely over a long season, may have particularly stunning form or colour, and has long, strong stems and good bloom substance. Dahlias can be used in many ways in the garden. Individual plants or small clusters within existing landscaping provide summer-long colour and highlight. Long straight rows look impressive and are easily managed and accessed for cutting blooms. Dahlias can also be planted as hedges. Large Dahlias can be situated as to provide background colour for other landscape plants. Small Dahlias can be intermixed with other plants or used as borders.

The Dahlia is also the official flower of the city of Seattle and the national flower of Mexico.

Comments

Older Dahlia varieties are propagated by dividing the large tuberous roots. New varieties are propagated from seeds, and rare varieties are propagated by grafting onto rootstocks. Generally propagation by cuttings is deemed best.

Most commonly grown Dahlias are hybrids of *D. pinnata* and *D. coccinea*.

Echinacea purpurea

Scientific Name

Echinacea purpurea (L.) Moench

Synonyms

Brauneria purpurea (L.) Britton, *Echinacea intermedia* Lindl. ex Paxton, *Echinacea purpurea* var. *arkansana* Steyerf., *Echinacea purpurea* f. *liggettii* Steyerf., *Echinacea purpurea* var. *serotina* (Nutt.) L.H. Bailey, *Echinacea serotina* (Sweet) D. Don ex G. Don f., *Echinacea speciosa* (Wender.) Paxton, *Helichroa purpurea* (L.) Raf. *Rudbeckia purpurea* L.

Family

Asteraceae

Common/English Names

Black Sampson, Comb Flower, Coneflower, Eastern Purple Coneflower, Echinacea, Indian Head, Missouri Snakeroot, Purple Coneflower, Red Sunflower.

Vernacular Names

Brazil: Equinácea, Equinocea, Flor De Cone (Portuguese)

Chinese: Zi Hua Song Guo Ju, Zi Zhui Ju

Czech: Třapatka Nachová

Danish: Have-Purpursolhat, Purpur Solhat, Solhat

Dutch: Kogelbloemsoort, Purperen Rudbeckia, Rode Zonnehoed

Eastonian: Purpur-Siilkübar

Finnish: Auringonhattu, Kaunopunahattu, Punahattu

French: Echinacée, Echinacée Pourpre, Rudbeckie Pourpre

German: Echinacea, Echinacin, Echter Sonnenhut, Kegelblume, Purpurroter Sonnenhut, roter Scheinsonnenhut, Roter Sonnenhut, Rudbeckie, Sonnenhut

Hungarian: Bíbor Kasvirág, Bíbor Kúpvirág, Lángvörös Kasvirág, Piros Kasvirág

Icelandic: Echinacea, Sólhattur

Italian: Echinacea Purpurea

Norwegian: Echinacea, Purpursolhatt, Rød Solhatt

Polish: Jeżówka Purpurowa, Jeżogłówka Purpurowa, Rudbekia Purpurowa

Portuguese: Equinácea Purpúrea

Russian: Echinacija purpurovaja

Slovaščina: Ameriški Slamnik, Purpurni Ameriški Slamnik, Škrlatni Ameriški Slamnik

Spanish: Echinacea

Swedish: Purpurrudbeckia, Röd Rudbeckia, Röd Solhatt

Turkish: Ekinazya, Güneş Çiçeği, Kipriceği, Kipriotu

Origin/Distribution

Eastern Purple Coneflower is native to eastern North America. It is present to some extent in the wild in much of the eastern, southeastern and midwest United States.

Agroecology

In its native temperate range, it occurs in open woodlands, thickets, prairies, near waterways and roadsides. It is extensively grown as ornamentals in gardens and parks and is also cultivated commercially as an herbal remedy.

E. purpurea thrives best in full sun and is shade intolerant. It is not fastidious of soil pH but plant prefers loamy or sandy, well-drained soils. It is also quite drought tolerant.

Edible Plant Parts and Uses

The petals are edible. Some dishes include echinacea Pane bagno (bathed bread) decorated with fresh echinacea petals and a wedge of lemon, American Indian savoury echinacea spread, echinacea and melon fruit salad (Roberts 2000). Petals are fried with watercress, onion and mustard leaves and spread over sweet potatoes.

Botany

A herbaceous perennial 5–120 cm high with erect, branched brownish-green glabrous or hairy stems (Plate 1) and fibrous roots. Leaves alternate, simple and lower leaves broader ovate (Plate 2) and petiolate with weakly winged petioles, lengths decreasing in upper leaves, lamina ovate lanceolate to narrowly lanceolate,

Plate 1 Echinacea in flowers and lanceolate upper leaves

Plate 2 Broadly ovate juvenile leaves

Plate 3 Close view of flowers with conic discs

5–30 by 5–12 cm, margins serrate, apex acute, base rounded to acute. Flowering heads solitary on stout terminal peduncle, 8–25 cm (Plates 1, 3 and 4). Involucral bracts linear to lanceolate. Receptacle with 9–15 mm palea, red orange tipped, slightly curve and pointed. Discs conic to subglobose 1.4–45.5 by 2–4 cm, disc florets corolla greenish to pink or purple, 1.5–4.5×2–4 cm. Ray florets corolla pink to purple pink to purple, laminae spreading to recurved,

Plate 4 Flowers with subglobose and flattish round discs

3–8 cm × 0.8–2 cm, two-toothed at apex, sparsely hairy abaxially (Plates 1, 3 and 4). Cypselae, 3–4 angled, glabrous, tan or bicoloured with a dark brown distal band, pappi persistent, 1.2 mm with 0–4 prominent teeth.

Nutritive/Medicinal Properties

Plant/Cell Culture Phytochemicals

Traces of pyrrolizidine alkaloids (0.006 %) tussilagine and isotussilagine were found in dried materials of *Echinacea angustifolia* and *E. purpurea* (Roder et al. 1984).

A 35-kDa water-soluble, acidic polysaccharide, 4-*O*-methyl-glucuronoarabinoxylan, was isolated from hemicellulosic fraction of *E. purpurea* and characterized by Wagner et al. (1984, 1985) and Proksch and Wagner (1987). The polysaccharide contained a (1 → 4)-linked β-D-xylan backbone with branching points at C-2 and C-3. Three homogeneous polysaccharides, two neutral fucogalactoxyloglucans with mean molecular weight of 10,000 and 25,000 and an acidic arabinogalactan with a mean molecular weight of 75,000 were isolated from the medium of *Echinacea purpurea* cell cultures (Wagner et al. 1988). An arabinogalactan protein (AGP) with molecular weight 1.2×10^6 Da, from pressed juice of *Echinacea purpurea*, was isolated from a high molecular weight fraction by precipitation with the β-glucosyl Yariv reagent (Classen et al. 2000). It comprised a high amount of polysaccharide

(83 %) with a ratio of galactose to arabinose of 1.8:1, some uronic acids (4–5 %) and a low-protein content (7 %) with high levels of serine, alanine and hydroxyproline. The amino acid profile in the arabinogalactan protein comprised serine 16 %, alanine 12.5 %, hydroxyproline 11.5 %, asparagine/aspartic acid 10.6 %, threonine 10.5 %, glutamine/glutamic acid 9.4 %, arginine 7.5 %, glycine 4.6 %, valine 4.1 %, histidine 3.7 %, lysine 3.3 %, leucine 2.5 %, isoleucine 2.2 % and phenylalanine 1.6 %. The monosaccharide profile in the arabinogalactan protein comprised galactose 59.1, arabinose 33.2, glucosamine 4.0 %, mannose 2.6 % and rhamnose 1.1 %. The molecular weight arabinogalactan protein (AGP) from the pressed juice of *Echinacea purpurea* was found to have hydroxyproline (42.9 % w/w) as the dominant amino acid and the major amino acid responsible for the binding between the protein and the arabinogalactan subunits via an *O*-glycosidic linkage (Volk et al. 2007). Large amounts of glutamine/glutamic acid (24.5 % w/w) and asparagine/aspartic acid (17.3 % w/w) were also found. Another arabinogalactan protein was purified from *E. purpurea* suspension culture (Classen 2007). It comprised high amount of polysaccharide (90 % w/w) with the dominating monosaccharides galactose and arabinose and some glucuronic acid and a small protein moiety (10 % w/w) with the main amino acids alanine, hydroxyproline, serine, glutamine/glutamic acid, asparagines/aspartic acid and threonine. The polysaccharide part was composed of a branched core-polysaccharide of 3-, 6- and 3,6-linked Galp residues with terminal Araf, Arap, Galp and GlcAp residues. Compared to an arabinogalactan protein from pressed juice of the aerial parts of *Echinacea purpurea*, differences particularly in terminal arabinose mono- and oligosaccharides in arabinogalactan (AG) side branches could be detected.

Two groups of minerals (I, Fe, Cu, Mn, Li and, II, Ca, Mg, Zn, Ni) were identified in the aerial parts and roots of *E. purpurea* in Serbia (Razić et al. 2003). The trace element profiles in the roots, stem, leaves and flowers were found to differ significantly.

The aerial parts of *Echinacea purpurea* afforded, in addition to known compounds, five highly unsaturated acetylenic amides and a derivative of linolen (Bohlmann and Hoffmann 1983). The aerial parts of *E. purpurea* were found to contain different structural types of alkamides; the roots yielded similar alkamide pattern (Bauer and Reminger 1989). Alkamide levels differed significantly among roots, rhizomes, stems, leaves and flowers of *E. purpurea* (Perry et al. 1997). Roots were distinguished from other plant parts by higher levels of the C12 diene-diyne alkamides, whereas levels of the C12 tetraene alkamides and C11 diene-diyne were highest in vegetative stems. The ratio of the 2 stereoisomeric C12 tetraene alkamides differed between flowers and all other *E. purpurea* parts. The alkylamides and cichoric acid in dried roots and aerial parts of *E. purpurea* grown in eastern Australia were determined as follows: total alkylamide concentration in root samples was 6.2 mg/g (range 1.2–12.1 mg/g) and in aerial samples was 1.0 mg/g (range 0.2–3.9 mg/g) (Wills and Stuart 1999). The cichoric acid concentration in root samples was 13.2 mg/g (range 1.4–20.5 mg/g) and in aerial samples was 12.9 mg/g (range 4.9–21.4 mg/g). Stuart and Wills (2000) found that total alkamide concentration in *E. purpurea* root, stem and leaf decreased throughout the first growing season while the concentration in flowers increased. In mature plants, the root contained about 70 % of the total plant alkamides with approximately 20 % in flower, 10 % in stem and 1 % in leaf tissue. The relative proportion of individual alkamides in the root did not change during plant growth, but cichoric acid concentration in plant tissues did decrease during plant senescence. Similar concentrations of cichoric acid were measured in root, flower and leaf tissues, but stem levels were lower. In mature plants, the flower and leaf each contained about 35 % of the total plant cichoric acid, while the root and stem contained approximately 20 and 10 %, respectively. Cichoric acid was the main phenolic in *E. purpurea* roots (mean 2.27 % summer, 1.68 % autumn) and tops (2.02 % summer, 0.52 % autumn) followed by caftaric acid was the other main phenolic compound in the roots (0.40 % summer, 0.35 % autumn) and tops (0.82 % sum-

mer, 0.18 % autumn) (Perry et al. 2001). Autumn-grown *Echinacea purpurea* plants in Taiwan produced more caffeoyl phenols, particularly cichoric acid and caftaric acid, in leaf and flower tissues than spring-grown plants (Chen et al. 2008). Iranian cultivated *E. purpurea* tops was found to have a high content of cichoric acid (3.5–5.7 %), followed by caftaric acid (3.1–4.5 %) and caffeic acid (0.6–1.1 %) with total polyphenol content of 7.9–10.9 %, (Iranshahi and Amanzadeh 2008). After 2 hours of boiling water extraction, the content of cichoric acid was 5.7 %, whereas the content of this acid in 60:40 ethanol–water extraction did not exceed 3.9 %.

For total alkamides, concentrations (mg/g dry weight basis) among individual *E. purpurea* plants varied from 5.02 to 27.67 (mean = 14.4 %) in roots, from 0.62 to 3.42 (mean = 1.54) in nearly matured seed heads, and from 0.22 to 5.25 (mean = 0.77) in young tops (about ½ flower heads, ¼ leaves, and ¼ stems) (Qu et al. 2005). For cichoric acid, concentrations among individual plants varied from 2.65 to 37.52 (mean = 8.95), from 2.03 to 31.58 (mean = 10.9) and from 4.79 to 38.55 (mean = 18.88) in the roots, the seed heads and the tops, respectively. Dodeca-2*E*,4*E*,8*Z*,10*E*-tetraenoic acid isobutylamide and dodeca-2*E*,4*E*,8*Z*,10*Z*-tetraenoic acid isobutylamide (alkamides 8/9) accounted for only 9.5 % of the total alkamides in roots but comprised 87.9 % in the seed heads and 76.6 % in the young tops. Two cinnamic acids, 2-*O*-caffeoyl-3-*O*-isoferuloyltartaric (3) and 2,3-di-*O*-isoferuloyltartaric acid (5), along with three known caffeic acids, cichoric acid (1), 2-*O*-caffeoyl-3-*O*-feruloyltartaric acid (2) and 2-*O*-caffeoyl-3-*O*-*p*-coumaroyltartaric acid (4), were isolated and purified from *Echinacea purpurea* (Lu et al. 2012). From 250 mg of crude extracts, 65.1 mg of 1, 8.3 mg of 2, 4.0 mg of 3, 4.5 mg of 4 and 4.3 mg of 5 were isolated, with purities of 98.5, 97.7, 94.6, 94.3 and 98.6 %, respectively.

Nineteen phenolics were identified in the medium of *E. purpurea* cell cultures after elicitation with biotic elicitors (Li and Barz 2005, 2006). The medium contained lignan, neolignan and acetophenone derivatives as the main elicitor-enhanced products. *E. purpurea* cells mainly contained phenolic glycosides including a new compound α -*O*- β -D-glucopyranosyl-acetovanillone.

Constitutive compounds identified in the cell culture medium of *E. purpurea* included α -hydroxyacetovanillone (1), coniferyl alcohol (4), methyl (*E*)-*p*-coumarate (7), and 1-hydroxypinoresinol (8). After elicitation of *E. purpurea* cell culture with yeast, the compounds found in the medium included α -hydroxyacetosyringone (2); 4-hydroxyacetophenone (3); 4,7,9,8'-tetrahydroxy-3,3',5'-trimethoxy-8,4'-oxy-9'-norneolignan-7'-one (5); 1-(4-hydroxy-3-methoxyphenyl)-2-(2-methoxy-4-[1-(*E*)-propen-3-ol]-phenoxy]-propane-1,3-diol (6a,b); 4,7,9-trihydroxy-3,3',5'-trimethoxy-8,4'-oxy-9'-norneolignan-7'-one (9); and buddlenol B (10). Phenolics found in *E. purpurea* cells were 4-hydroxyacetophenone (3); scopoletin (11); 4-hydroxybenzoic acid glucose ester (12); 4-*O*- β -glucopyranosylacetophenone (13); α -*O*- β -D-glucopyranosyl-acetovanillone (14); 4-*O*- β -glucopyranosylconiferyl alcohol (15); scopolin (16); 1-(4-*O*-B-glucopyranosyl-3-methoxyphenyl)-2-(2-methoxy-4[1-(*E*)-propen-3-ol]-phenoxy]-propane-1,3-diol (17a,b); 4(*O*- β -D-glucopyranosyl)-7,9-dihydroxy-3,3',5'-trimethoxy-8,4'-oxy-9'-norneolignan-7'-one (18); 1-(4-hydroxy-3-methoxyphenyl)-2-(2-methoxy-4-[1-(*E*)-propen-3-ol]-phenoxy]-propane-1,3-diol (6a,b); and longiloroside (19). The optima accumulation of *Echinacea purpurea* suspension culture biomass (73.6 g/l FW and 10.03 g/l DW), phenolics (61.14 mg/g DW) and flavonoids (38.30 mg/g DW) was achieved in 0.5 MS (Murashige and Skoog) medium (Wu et al. 2007b). High adventitious root biomasses (83.1 g/l FW and 15.30 g/l DW) were achieved with feeding of the 0.5 MS medium at the end of 2nd week. This led to slight decreases in the total production of phenolics and flavonoids; however, this feeding was responsible for increases in the accumulation of caftaric acid (5.76 mg/g DW) and cichoric acid (26.12 mg/g DW).

Beside the above, many other studies had isolated and identified alkamides and caffeic acid derivatives in *E. purpurea* plant, various plant parts and products (Bergeron et al. 2000; Laasonen et al. 2002; Mølgaard et al. 2003). Ultrasonic extraction of dried samples of *E. purpurea* roots and aerial parts with methanol–water (7:3) or ethanol–water (7:3) gave good yields of cichoric acid, echinacoside and the

alkamides, undeca-2*E*,4*Z*-diene-8,10-diynoic acid isobutylamide and a mixture of dodeca-2*E*,4*E*,8*Z*,10*E/Z*-tetraenoic acid isobutylamides (recoveries of 89, 85, 80 and 90 %, respectively) (Bergeron et al. 2000). The HPLC separation of the phenolic compounds cichoric acid, chlorogenic acid and echinacoside was also improved by careful attention to the pH of the mobile phase. The profile of phenolic compounds (mean concentration $\mu\text{g/ml}$) in *E. purpurea* herb was determined as 0–767 μg caftaric acid, 0–45 μg chlorogenic acid, 0–220 μg caffeic acid, 0 μg cynarin, 0–2,879 μg cichoric acid, 0 μg echinacoside and 0–25 μg tet 8/9 (dodeca-2*E*,4*E*,8*Z*,10*E/Z*-tetraenoic acid isobutylamide) (Vimalanathan et al. 2005).

Studies showed that the content of caffeic acid derivatives in *E. purpurea* aerial parts and roots reached its highest in the middle stage of full blossoming (Liu et al. 2007). The content of caffeic acid derivatives in fresh raw material was generally higher than that in dried raw material. The developmental pattern of total phenolics in *E. purpurea* was the same as that of caffeic acid derivatives. The stage of mid-bloom was the optimal harvesting period for both caffeic acid derivatives and total phenolics. There was no significant difference in the content of caffeic acid derivatives among three Chinese geographical populations of *E. purpurea*.

E. purpurea extracts stored for 18 months were found to contain caftaric acid, cichoric acid and undeca-2*Z*,4*E*-diene-8,10-diynoic acid isobutylamide at concentrations of 0.7, 0.71 and 2.0 mg/ml, respectively (Cech et al. 2006). Using HPLC/electrospray ionization mass spectrometry, isomeric isobutylamides and 2-methylbutylamides could be distinguished. The cichoric acid was the main phenolic compound detected in dried *E. purpurea* materials (flowers, leaves, stems and roots), followed by caftaric acid (Lin et al. 2011). The bioactive constituent contents in different plant parts were in the descending order: flowers > leaves > stems > roots. Both caffeic acid derivatives and total phenolics contents were affected by drying method and storage/packing condition. Cool wind-dried materials retained more bioactive constituents content (>85 %) compared to vacuum freeze-dried materials.

The storability results indicated that the freeze-dried *E. purpurea* materials sealed in polyethylene terephthalate/aluminium foil/polyethylene or nylon/polyethylene bags and stored under 10–20 °C and 40–60 % relative humidity without light conditions retained the highest content of bioactive compounds.

Flower Phytochemicals

Volatiles in the headspace of *E. purpurea* flowers were acetaldehyde, dimethyl sulphide, 2-methylpropanal and acetone, 2-butanone, 2-methylbutanal, 3-methylbutanal, unknown, α -pinene, camphene, hexanal, β -pinene, sabinene/ β -thujene, unknown, 2-methyl-4-pentenal, β -myrcene, α -terpinene, limonene, 2-hexenal (*trans*), ocimene, γ -terpinene, *trans*-ocimene, *p*-cymene, α -terpinolene, unknown, 1-hexanol, *allo*-ocimene, 3-hexen-1-ol (*cis*), 2-hexen-1-ol (*trans*) and α -cubebene/ α -copaene (Mazza and Cottrell 1999). Major volatiles in headspace of flower tissues were myrcene 43 %, β -pinene 7.4 %, α -pinene 22.6 % and dimethyl sulphide 1.0 %.

The essential oil of *E. purpurea* flower heads was found to contain 89 components of which 63 (monoterpene hydrocarbons, oxygenated monoterpenes, sesquiterpenes, oxygenated sesquiterpenes) were identified comprising 92.8 % of the total oil yield (Diraz et al. 2012). The major components were germacrene D (11.3 %), caryophyllene oxide (8.7 %), β -caryophyllene (7.2 %) and α -cadinol (6.2 %). The other components higher than 1 % included β -pinene (1.3 %), α -phellandrene (2.9 %), *p*-cymene (2.65), β -elemene (2.1 %), α -cadinene (1.0 %), naphthalene, 1,2,3,5,6,8a-hexahydro-4,7-dimethyl-1-(1-ethylethyl)-, (1*S*-*cis*)- (3.3 %), α -farnesene (1.0 %), 1,5-epoxysalvia-4(14)ene (3.3 %), naphthalene, 1,2,3,4,4a,7-hexahydro-1,6-dimethyl-4-1(1-methylethyl)- (1.6 %), α -bisabolene (2.3 %), bicyclo[4.4.0]dec-1-ene,2-isopropyl-5-methyl-9-methylene- (1.8 %), α -cadinene (2.0 %), decanone (1.5 %), ethyl oleate (1.6 %), vulgarol B (1.9), aromadendrene oxide (1.1 %), 3,4,-difloro-4-methoxybiphenyl (2.7 %), isoaromadendrene epoxide (1.9 %), *trans* (Z)- α -bisabolene epoxide

(2.3 %), benzenepropanoic acid, octadecyl ester (1.2 %) and diepi- α -cedrene epoxide (1.2 %). Earlier, 36 compounds comprising 70.9 % of sesquiterpenes and 6.4 % monoterpene hydrocarbons were identified in the *E. purpurea* flower-head essential oil in Iran (Mirjalili et al. 2006). Germacrene D (57 %) was the major component.

Rutin and nicotiflorin (3-*O*-rutinoside campherol) were isolated from the flowers, the latter flavonoid being dominant (Kurkin et al. 2011). The major anthocyanins of *Echinacea purpurea* and *E. pallida* were identified as cyanidin 3-*O*-(β -D-glucopyranoside) and cyanidin 3-*O*-(6-*O*-malonyl- β -D-glucopyranoside) (Cheminat et al. 1989). Cyanidin 3-*O*-(β -D-glucopyranoside) (9.8 mg) and cyanidin 3-*O*-(6''-*O*- β -D-glucopyranoside) (14.3 mg) were obtained from 160 mg crude flower extract with a purity of 95.1 and 98.2 %, respectively (Li et al. 2012).

The profile of phenolic compounds (mean concentration μ g/ml) in *E. purpurea* flower was determined as 19–1,212 μ g caftaric acid, 0–208 μ g chlorogenic acid, 11–179 μ g caffeic acid, 0–13 cynarin, 9–734 μ g cichoric acid, 0 μ g echinacoside, and 0–39 μ g tet 8/9 (dodeca-2*E*,4*E*,8*Z*,10*E*/*Z*-tetraenoic acid isobutylamide) (Vimalanathan et al. 2005). In *Echinacea purpurea* cultivars Magnus and White Swan and line CLS-P2, harvested dry flower heads contained highest cichoric acid content and followed by caftaric acid and chlorogenic acid (Chen et al. 2009). The contents of cynarin and echinacoside in flower heads were relatively low as compared to cichoric acid, caftaric acid or chlorogenic acid. Total caffeoyl derivatives content were 125.3, 116.7 and 145.5 mg/g dry weight for line CLS-P2, Magnus and White Swan, respectively. The alkamides dodeca-2*E*,4*E*,8*Z*,10*E*-tetraenoic acid isobutylamide (alkamide 8) and dodeca-2*E*,4*E*,8*Z*,10*Z*-tetraenoic acid isobutylamide (alkamide 9) were also found in the flower heads, but their content was much lower than in the roots. No statistically significant differences in flower-head alkamides 8 and 9 content were found among the tested *E. purpurea* cultivars and lines.

The extraction yields of phenolics of freeze-dried *E. purpurea* flowers were significantly

affected by the ethanol concentrations at 25 °C with water extraction giving the highest extraction yield (39.8 %) (Tsai et al. 2011). When the ethanol volume percentage in the solvent was increased from 25 % up to 95 %, the extraction yields were decreased from 36.9 to 3.3 %. Water extraction yielded 1,656 mg/g extract of caftaric acid, 0.14 mg chlorogenic acid, 0.53 mg echinocside, 37.23 mg cichoric acid, total caffeic acid derivatives 54.45 mg and total phenolics 97.07 mg. For caftaric acid, ethanol extraction (50 %) yielded the highest 67.07 mg down to 16.35 mg (ethanol 95 %); for chlorogenic acid, ethanol (75 %) gave 2.84 mg down to 0.53 mg at ethanol 95 %; for echinacoside, ethanol (75 %) gave 1.07 mg down to 0.54 mg at ethanol 95 %; for cichoric acid, ethanol extraction (50 %) yielded the highest 180.29 mg down to 42.54 mg (ethanol 95 %). For total caffeic acid derivatives, ethanol extraction (50 %) yielded the highest 250.79 mg down to 59.96 mg (ethanol 95 %). For total phenolics, ethanol extraction (50 %) yielded the highest 441.33 mg down to 104.47 mg (ethanol 95 %). The total phenols, individual and total caffeic acid derivatives contents of extracts were enhanced by elevated extraction temperatures ranged from 25 to 65 °C.

The content of cichoric acid and caftaric acids in dried *E. purpurea* flowers were found to be significantly affected by the drying methods used (Kim et al. 2000b). Although significant loss of cichoric acid was observed when flowers were stored at high moisture, vacuum microwave-dried flowers with a low-moisture content retained the highest levels of cichoric acid and caftaric acid similar to freeze-dried flowers. Flowers that were air-dried at 25 °C retained about 50 %, while those air-dried at 70 °C had lowest retention of these acids. Although flowers air-dried at 40 °C retained relatively high amounts of cichoric acid and caftaric acid, the time (55 hours) required to reach optimal drying was considerably longer than that (47 minutes) for vacuum microwave drying. They also found that individual alkamide concentrations in roots and leaves were affected by the drying methods used (Kim et al. 2000a). To preserve higher levels of total alkamides, freeze-drying was found to be

the best method, vacuum microwave drying was a superior method for drying roots than air-drying at 70 °C, while air-drying at 50 °C was the preferred method for drying leaves of *E. purpurea*.

Fruit (Achene)/Seed Phytochemicals

Two major alkamide peaks were identified in *E. purpurea* achenes as undeca-2*E*,4*Z*-diene-8, 10-diynoic acid isobutylamide and dodeca-2*E*, 4*E*,8*E*,10*E/Z* tetraenoic acid isobutylamide (8/9) (He et al. 1998). The isomer pair, tetraene 8/9, was purified as a standard for quantification of alkamide content in *E. purpurea* achenes and roots.

Seed oil yields of *E. angustifolia*, *E. pallida* and *E. purpurea*, harvested in 1998 and 1999, ranged from 13 to 23 % (Oomah et al. 2006). Vitamin E content of the oils ranged from 29 to 85 mg/100 g oil, with α -tocopherol constituting 83 % of the total tocopherol. The oil was highly polyunsaturated and abundant in linoleic, oleic and palmitic acids, together comprising 95 % of the total fatty acids. *E. purpurea* seed oils contained 66.5 % linoleic, 21.4 %, oleic and 8 % palmitic acids in the 1998 year harvest and 75.6 % linoleic, 12.2 % oleic and 7 % palmitic acids in the 1999 harvest. Fruit (achenes) of *E. purpurea* was found to contain 33.6 % light yellow fatty oil comprising 78.4 % unsaturated fatty acids and 21.6 % saturated fatty acids; the major components were linoleic acid (58.2 %) and oleic (20.2 %) acid, and the equivalent iodine number was 121 (Vandyshev et al. 2009). Eighteen components were identified in *E. purpurea* seed oil, comprising 90.4 % of total area with petroleum ether solvent and 96 % with solvent *n*-hexane solvent (Diraz et al. 2012). The most abundant fatty acids were palmitic acid, stearic acid, oleic acid, and linoleic acid. The fatty acid profile using petroleum ether and *n*-hexane solvents were, respectively, as follows: oleic acid C18:1 (48 %, 29 %), palmitic acid C16:0 (16.6 %, 9.2 %), linoleic acid C18:2 (13.3 %; 51 %), oxocool C13 (0.1 %, 0 %), myristic acid C14:0 (0.3 %, 0.2 %), pentadecanoic acid C15:0 (0.1 %, 0.1 %), palmitoleic acid C16:1

(1 %, 0.4 %), carbonic acid C17:0 (0.2 %, 0.1 %), heptadecanoic acid C17:1 (0.2 %, 0 %), stearic acid C18:0 (5 %, 2.5 %) elaidic acid C18:1 (0.7 %, 0 %), linolelaidic acid C18:2 (0.8 %, 0 %), arachidic acid C20:0 (0.5 %, 0.6 %), gamma-linolenic acid C18:3 (0 %, 0.5 %), eicosenoic acid C20:1 (0.3 %, 0.5 %), behenic acid C22:0 (1.3 %, 0.7 %), tricosanoic acid C23:0 (0.1 %, 0.1 %), lignoceric acid C24:0 (0.6 %, 0.3 %) and oxiraneoctanoic acid C26 (0.8 %, 0.8 %). Oxocol, heptadecenoic acid, elaidic acid and linolelaidic acid could not be defined with solvent *n*-hexane.

Leaf Phytochemicals

Volatiles in the headspace of *E. purpurea* leaf tissues were acetaldehyde, dimethyl sulphide, propanal, 2-methylbutanal, 3-methylbutanal, 2-ethylfuran, pentanal, α -pinene, α -thujene, camphene, hexanal, β -pinene, sabinene/ β -thujene, pentanal, 2-methyl-4-pentenal, β -myrcene, α -terpinene, limonene, 2-hexanal (*cis*), 2-hexenal (*trans*), ocimene, γ -terpinene, *trans*-ocimene, *p*-cymene, hexyl acetate, α -terpinolene, 3-hexen-1-ol-acetate, 1-hexanol, *allo*-ocimene 3-hexen-1-ol (*cis*), α -ylangene, γ -cadinene, *trans*-caryophyllene, calarene/ α -copaene, germacrene D/ α -cubebene, 5-ethyl-2(5*H*)-furanone, δ -cadinene, $\beta\alpha$ -cubebene/ γ -cadinene and 2,2,3,3-tetramethyl hexane (Mazza and Cottrell 1999). Major volatiles in headspace of leaf tissues were myrcene 27 %, β -pinene 1.9 %, α -pinene 12.1 %, dimethyl sulphide <1.0 %

Total phenolic contents reported for *E. purpurea* (leaf) were 15.15 mg GAE/100 g DW (Wojdyło et al. 2007). Major phenolic compounds (mg/100 g DW) found were phenolic acids, 620 mg caffeic acid, 115 mg neochlorogenic acid, 19.5 mg *p*-coumaric acid and 17.9 mg ferulic acid, and flavonoids, 12.4 mg quercetin.

In *Echinacea purpurea* cultivars Magnus and White Swan and line CLS-P2, harvested dry leaves contained highest cichoric acid content and followed by caftaric acid and echinacoside (Chen et al. 2009). The contents of chlorogenic acid and cynarin in leaves were relatively low as

compared to cichoric acid, caftaric acid and chlorogenic acid. Among the five caffeoyl derivatives examined, CLS-P2 leaves had greater cichoric acid, caftaric acid, cynarin and echinacoside levels than Magnus and White Swan. Total caffeoyl derivatives content were 61.73, 31.75 and 20.02 mg/g dry weight for line CLS-P2, cultivar Magnus and cultivar White Swan, respectively. Line CLS-P2 had the highest dodeca-2*E*,4*E*,8*Z*,10*E*-tetraenoic acid isobutylamide (alkamide 8) and dodeca-2*E*,4*E*,8*Z*,10*Z*-tetraenoic acid isobutylamide (alkamide 9) content in dry leaves among the tested cultivars and line. The profile of phenolic compounds (mean concentration μ g/ml) in *E. purpurea* leaf and stem was determined as 0–1,174 μ g caftaric acid, 0–63 μ g chlorogenic acid, 0–421 μ g caffeic acid, 0–5 cynarin, 0–6,001 μ g cichoric acid, 0 μ g echinacoside and 0.19 μ g tet 8/9 (dodeca-2*E*,4*E*,8*Z*,10*E*/*Z*-tetraenoic acid isobutylamide) (Vimalanathan et al. 2005).

Stem Phytochemicals

Volatiles in the headspace of *E. purpurea* stem tissues were acetaldehyde, dimethyl sulphide, 2-methylpropanal and acetone, 2-methylbutanal, 3-methylbutanal, α -pinene, geranyl acetate, camphene, hexanal, β -pinene, sabinene/ β -thujene, unknown, 2-methyl-4-pentenal, β -myrcene, α -terpinene, limonene, 2-hexenal (*trans*), ocimene, γ -terpinene, *trans*-ocimene, α -terpinolene, 3-hexen-1-ol-acetate, 1-hexanol, *allo*-ocimene, 3-hexen-1-ol (*cis*), 2-hexen-1-ol (*trans*), α -cubebene/ α -copaene, α -ylangene, α -ylangene, germacrene D/ α -cubebene, δ -cadinene and $\beta\alpha$ -cubebene/ γ -cadinene (Mazza and Cottrell 1999). Major volatiles in headspace of stem tissues were myrcene 45 %, β -pinene 4.4 %, α -pinene 33.7 % and dimethyl sulphide <1.0 %.

Root Phytochemicals

Volatiles in the headspace of *E. purpurea* roots were acetaldehyde, dimethyl sulphide, 2-methylpropanal and acetone, 2-propenal,

2-methylbutanal, 3-methylbutanal, ethanol, 1-methylpropyl acetate, trichloroacetic acid, α -pinene, camphene, hexanal, β -pinene, 2-methyl-1-propanol, sabinene/ β -thujene, α -phellandrene, α -terpinene, heptanal, limonene, 2-methyl-1-butanol, 3-methyl-1-butanol, ocimene, *p*-cymene, hexyl acetate, unknown, 6-methyl-5-hepten-2-one, 1-hexanol and 1-octen-3-ol, benzaldehyde (Mazza and Cottrell 1999). Major volatiles in headspace of root tissues were 0%, β -pinene 0.2 %, α -pinene 0.6 %, α -phellandrene 16.7 % and dimethyl sulphide 14.7 %. The seventeen lipophilic, volatile to semivolatile components, including the 11 alkamides known to *E. purpurea* roots, were identified (Hudaib et al. 2002). Cucumber mosaic cucumovirus infection was found to be responsible for significant variations in the relative compositions of the major constituents, in particular germacrene D, dodeca-2*E*, 4*E*, 8*Z*, 10*Z*(*E*)-tetraenoic acid isobutylamide *cis/trans* isomers, undeca-2*Z*, 4*E*-diene-8, 10-diynoic acid isobutylamide and dodeca-2*E*, 4*Z*-diene-8, 10-diynoic acid isobutylamide.

Root extracts of *E. purpurea* root were found to contain ($\mu\text{g/ml}$) chlorogenic acid (0.0157 μg), caftaric acid (0.1568 μg), cafeic acid (trace), cichoric acid (1.0147 μg) alkamides 1 undeca-2*E*-4*Z*-diene-8,10-diynoic acid isobutylamide (0.056 μg), undeca-2*Z*-4*E*-diene-8,10-diynoic acid isobutylamide (0.0159 μg), dodeca-2*E*,4*Z*-diene-8,10-diynoic acid isobutylamide (0.0130 μg), undeca-2*E*,4*Z*-diene-8,10-diynoic acid 2-methylbutylamide (trace), dodeca-2*E*,4*E*,10*E*-trien-8-ynoic acid isobutylamide (0.0156 μg), dodeca-2*E*,4*E*-diene-8,10-diynoic acid 2-methylbutylamide (0.0092 μg), dodeca-2*E*,4*E*,8*Z*,10*E*-tetraenoic acid isobutylamide (0.2912 μg), dodeca-2*E*,4*E*,8*Z*,10*Z*-tetraenoic acid isobutylamide (0.0396 μg), dodeca-2*E*,4*E*,8*Z*, trienoic acid isobutylamide (0.0102 μg) and undeca-2*E*-ene-8,10-diynoic acid isobutylamide (0.0106 μg) (Bauer et al. 1988; Bauer and Remiger 1989; Binns et al. 2002b; Perry et al. 2001; Hall 2003; Senchina et al. 2006; Pietta et al. 1998; Gotti et al. 2002; Pomponio et al. 2002; Solco 2007). No cynarin and echinacoside were detected in the roots. Five alkylamides, undeca-2*E*,4*Z*-dien-8,10-diynoic acid isobutyl-

amide, dodeca-2*E*,4*Z*-dien-8,10-diynoic acid isobutylamide, dodeca-2*E*,4*E*,10*E*-trien-8-ynoic acid isobutylamide, dodeca-2*E*,4*E*,8*Z*-trienoic acid isobutylamide and dodeca-2*E*,4*Z*-dien-8,10-diynoic acid 2-methylbutylamide, were isolated from the roots (Bauer et al. 1988). Nine alkamides were identified in the root of *E. purpurea* (He et al. 1998) similar to the fingerprint reported by Bauer and Remiger (1989). Several minor alkamides were also tentatively identified.

The following alkamides were identified in fresh and dry root extracts of *E. purpurea* (Spelman et al. 2009): undeca-2*E*,4*Z*-diene-8,10-diynoic acid isobutylamide (A); undeca-2*Z*,4*E*-diene-8,10-diynoic acid isobutylamide (B); undeca-2*E*-ene-8,10-diynoic acid isobutylamide (C); undeca-2*E*,4*Z*-diene-8,10-diynoic acid 2-methylbutylamide (D); undeca-2*Z*,4*E*-diene-8,10-diynoic acid 2-methylbutylamide (*E*, new); dodeca-2*Z*,4*E*-diene-8,10-diynoic acid isobutylamide (F); dodeca-2*E*,4*Z*-diene-8,10-diynoic acid isobutylamide (G); dodeca-2*E*,4*E*,10*E*-trien-8-ynoic acid isobutylamide (H); dodeca-2*E*,4*E*,8*Z*,10*E*-tetraenoic acid isobutylamide (I); dodeca-2*E*-ene-8,10-diynoic acid isobutylamide (J, used as standard); dodeca-2*E*,4*E*, 8*E*,10*Z*-tetraenoic acid isobutylamide (K); dodeca-2*E*,4*E*, 8*Z*,10*Z*-tetraenoic acid isobutylamide (L, used as standard); dodeca-2*E*,4*E*,8*Z*-trienoic acid isobutylamide (M); dodeca-2*E*,4*E*-dienoic acid isobutylamide (N); dodeca-2*E*,4*E*-dienoic acid isobutylamide (O); trideca-2*E*,7*Z*-diene-8,10-diynoic acid isobutylamide (P); dodeca-2*E*,4*Z*-diene-8,10-diynoic acid 2-methylbutylamide (Q); and dodeca-2,4,8,10-tetraenoic acid 2-methylbutylamide (R). Quantities of the isomeric alkylamides K, L and M and alkylamide J in ethanol extracts of *E. purpurea* root were determined in terms of concentrations of the isomeric tetraenes (compounds K, L and M) and dodeca-2*E*-ene-8,10-diynoic acid isobutylamide (compound J) per ml of solvent. The three different *Echinacea* root extracts, fresh 1:2, dry 1:11 and dry 1:5, all contained these alkylamides. However, the dry 1:5 extract contained the greatest amount of these compounds. All three extraction techniques investigated here (fresh 1:2, dry 1:5 and dry 1:11) resulted in very similar

alkylamide profile and gave similar yields of alkylamides and of total dissolved solids. The similarity in alkylamide content in fresh 1:2 and dry 1:11 extracts indicated that drying of root material at 50 °C did not result in a loss of alkylamides. It was concluded that either fresh or dried roots could be used to prepare extracts with high alkylamide content, although the overall yield was slightly lower for fresh extracts.

Caffeic acid derivatives, caftaric acid, chlorogenic acid, caffeic acid, cichoric acid and alkamides: undeca-2*E*,4*Z*-diene-8,10-diynoic acid isobutylamide; undeca-2*Z*,4*E*-diene-8,10-diynoic acid isobutylamide; dodeca-2*Z*,4*E*-diene-8,10-diynoic acid isobutylamide; undeca-2*E*,4*Z*-diene-8,10-diynoic acid 2-methylbutylamide; dodeca-2*E*,4*E*,10*E*-triene-8-ynoic acid isobutylamide; trideca-2*E*,7*Z*-diene-10,12-diynoic acid isobutylamide; dodeca-2*Z*,4*E*-diene-8,10-diynoic acid isobutylamide; dodeca-2*E*,4*Z*-diene-8,10-diynoic acid 2-methylbutylamide; dodeca-2*E*,4*E*,8*E*,10*Z*-tetraenoic acid isobutylamide, dodeca-2*E*,4*E*,8*Z*-trienoic acid isobutylamide; and dodeca-2*E*,4*E*-dienoic acid isobutylamide, were detected in the roots and extracts (Luo et al. 2003). Three alkamides and nitidanin diisovalerianate were identified, together with 14 known alkamides and one sesquiterpene from the roots of *Echinacea purpurea* (Hohmann et al. 2011). Cichoric acid and verbascoside predominated in extracts of *E. purpurea* roots (Sloley et al. 2001). A total of 16 alkamides, three ketoalkenes, two ketoalkynes and four phenolic acids (echinacoside, cichoric acid, caftaric acid and chlorogenic acid) were identified in aqueous ethanol (70 %) root extracts of *Echinacea purpurea* and *Echinacea pallida* (Thomsen et al. 2012). The major alkamides in the roots of *E. purpurea* were at their lowest concentration in the middle of autumn and early winter, while all of the major phenolic acids were at their highest concentrations in spring. In *E. purpurea* root extract, the major alkamide, dodeca-2*E*,4*E*,8*Z*,10*E*/*Z*-tetraenoic acid isobutyl amide, was not significantly affected by storage at any of the temperatures (−20, 25 and 40 °C), but cichoric acid content declined significantly at both 25 and

40 °C as compared to low-temperature storage (Livesey et al. 1999). In the root powder, the major alkamide showed a significantly reduced level at 25 and 40 °C, while cichoric acid did not decline significantly.

Biomass accumulation and production of caffeic acid derivatives (caftaric acid, chlorogenic acid and cichoric acid) in *Echinacea purpurea* adventitious root cultures was optimal under incubation temperature of 20 °C among the different incubation temperatures tested (10, 15, 20, 25 and 30 °C) (Wu et al. 2007a). Biomass of adventitious roots was highest in cultures grown under dark, while accumulation of caffeic acid derivatives was optimum in the cultures grown under 3/21 hours light and dark cultural regimes. Studies found that 15-day-old hairy root culture stimulated every 5 days by ultrasound for 6 minutes produced the highest amount of caffeic acid derivatives (CADs) after 30 days of culture among all ultrasound treatment experiments (Liu et al. 2012). The obvious increase of CADs production in *E. purpurea* hairy roots stimulated by ultrasound was related to the increase of both rolB-regulated endogenous indole-3-acetic acid biosynthesis and phenylalanine ammonium lyase (PAL) activity.

In *Echinacea purpurea* cultivars Magnus and White Swan and line CLS-P2, harvested dry roots contained highest cichoric acid content and then followed by caftaric acid, cynarin, echinacoside and chlorogenic acid (Chen et al. 2009). The caffeoyl derivatives were 16.53, 19.71 and 27.40 mg/g dry weight for CLS-P2, Magnus and White Swan, respectively. Compared to flowers and leaves, roots contained the highest content of alkamides, dodeca-2*E*,4*E*,8*Z*,10*E*-tetraenoic acid isobutylamide (alkamide 8) and dodeca-2*E*,4*E*,8*Z*,10*Z*-tetraenoic acid isobutylamide (alkamide 9). White Swan accumulated considerably higher alkamides 8 and 9 content in dry roots than Magnus and line CLS-P2.

Highly water-soluble fructans were isolated from *E. purpurea* roots (Wack and Blaschek 2006). The fructans represented linear inulin-type fructans with almost exclusively β-(2 → 1)-linked fructosyl units, terminal glucose

and terminal fructose. Small proportions of β -(2 \rightarrow 1,2 \rightarrow 6)-linked branch point residues were detected. 80 % ethanol-insoluble fructan from *E. purpurea* showed an average mean degree of polymerization of 35, 60 % ethanol-insoluble fructan of 44, and 40 % ethanol-insoluble fructan of 55.

Commercial *Echinacea* extracts are manufactured primarily from three *Echinacea* species, namely, *Echinacea purpurea* (herb, roots or seeds), *E. angustifolia* (roots) and *E. pallida* (roots) (Mahady et al. 2001). Current recommendations for use of these products include oral administration for the prophylaxis and treatment of the common cold, bronchitis, influenza and bacterial and viral infections of the respiratory tract. However, based on existing data products containing pressed juice or hydroalcoholic extracts, *Echinacea purpurea* (leaf juice and roots) and *E. pallida* (roots) had the most convincing data supporting their use. According to Spelman et al. (2009), *Echinacea purpurea*, a top-selling botanical medicine, is currently of considerable interest due to immunomodulatory, antiinflammatory, antiviral and cannabinoid receptor 2 (CB₂)-binding activities of its alkylamide constituents. It is an immunostimulating drug, containing multiple bioactive substances such as polysaccharides, caffeic acid derivatives (caffeic acid, cichoric acid, caftaric acid, chlorogenic acid), alkamides and glycoproteins (Manček and Kreft 2005). Among the many pharmacological properties reported for *E. purpurea* extracts, immunomodulation of macrophages had been demonstrated most convincingly (Barrett 2003). Several dozen clinical studies—including a number of blind randomized trials—had reported health benefits. The most robust data were from studies testing *E. purpurea* extracts in the treatment for acute upper respiratory infection. Although indicative of modest benefit, these studies were limited both in size and in methodological quality. Although a great deal of moderately good-quality scientific data regarding *E. purpurea*, effectiveness in treating illness or in enhancing human health exist, much has not yet been proven beyond a reasonable doubt.

Numerous studies had shown that *E. purpurea* exhibited immunostimulating, antimicrobial, antiinflammatory, antioxidant, cytochrome enzyme inhibitory, antiandrogenic, cannabinoidomimetic, radioprotective and antitumorous activities (Gupta et al. 2012).

Antioxidant Activity

The mechanisms of antioxidant activity of extracts derived from *E. angustifolia*, *E. pallida* and *E. purpurea* roots included free radical scavenging and transition metal chelating (Hu and Kitts 2000). Root extracts of these *Echinacea* spp. were capable of scavenging hydroxyl, DPPH and ABTS radicals. These root extracts delayed the formation of conjugated diene hydroperoxide induced by the thermal decomposition of 2, 2'-azobis(2-amidinopropane) dihydrochloride and protracted the lag phase of peroxidation of soybean liposomes. These root extracts also suppressed the oxidation of human low-density lipoprotein, as evaluated by reduced agarose electrophoretic mobility following oxidative modification by Cu²⁺.

Studies showed that *E. purpurea* extracts had antioxidant activity similar to that of ascorbic acid but had no serious effect on inhibiting chicken's peripheral blood mononuclear cells viability (Lee et al. 2009). In 2,2-diphenyl-1-picryl hydrazyl radical (DPPH) scavenging capacity, the ED₅₀ for the extract was measured at 0.23 mg/ml. The superoxide anions scavenging capacity of the extract was nearly equivalent to ascorbic acid (91.1 % vs. 93.0 %) at the same concentration of 1.6 mg/ml, and ED₅₀ was 0.32 and 0.13 mg/ml, respectively. Reducing power of the extract increased linearly with its concentration, and the concentration at 2.0 mg/ml reached about 65 % of ascorbic acid at 0.3 mg/ml. The chelating capacity of ferrous iron (Fe²⁺) was 70 % as good as that of the synthetic metal chelater EDTA when added to 5.0 mg/ml of *E. purpurea* extract. The polysaccharides content of the extract was 159.8 mg/g dry weight (DW), and total phenolic compound was 11.0 mg gallic acid equivalent/g

DW. Microculture tetrazolium assays showed extracts had 92 % cell viability at 1.6 mg/ml for chicken's peripheral blood mononuclear cells (PBMCs) and 84 % for RAW 264.7 macrophages, neither reaching the IC_{50} level.

Extracts of the roots and leaves of *E. purpurea* were found to have antioxidant properties in a free-radical scavenging assay and in a lipid peroxidation assay (Sloley et al. 2001). The methanol root extract of *E. purpurea*, *E. pallida* and *E. angustifolia* exhibited DPPH antioxidant activity with EC_{50} values of 134, 167 and 231 μ g/ml, respectively (Pellati et al. 2004). The radical scavenging activity of *Echinacea* root extracts reflected their phenolic content. The total phenolic content was 23.23 mg/g for *E. purpurea*, 17.83 mg/g for *E. pallida* and 10.49 mg/g for *E. angustifolia*. Caftaric acid, chlorogenic acid, caffeic acid, cynarin, echinacoside and cichoric acid were identified and quantified in *Echinacea* roots and derivatives. Pure echinacoside had the highest capacity to quench DPPH radicals (EC_{50} =6.6 μ M), while caftaric acid had the lowest (EC_{50} =20.5 μ M).

The antioxidant activity of three extracts, one alkamide fraction, four polysaccharide-containing fractions, and three caffeic acid derivatives from *Echinacea purpurea* root was evaluated by measuring their inhibition of in-vitro Cu(II)-catalyzed oxidation of human low-density lipoprotein (LDL) (Dalby-Brown et al. 2005). Among the extracts the 80 % aqueous ethanol extract exhibited ten times longer lag phase prolongation (LPP) than the 50 % ethanol extract, which in turn exhibited a longer LPP than the water extract. The antioxidant activity of the tested *Echinacea* extracts, fractions and isolated compounds was dose dependent. Synergistic antioxidant effects of *Echinacea* constituents were found when cichoric acid (major caffeic acid derivative in *E. purpurea*) or echinacoside (major caffeic acid derivative in *Echinacea pallida* and *Echinacea angustifolia*) was combined with a natural mixture of alkamides and/or a water extract containing the high molecular weight compounds.

The extracts of the stems, leaves and roots of *Echinacea purpurea* and their constituent cichoric

acid were found to be efficient scavengers of DPPH radicals with an activity comparable to that of rosmarinic acid, a well-characterized antioxidant (Thygesen et al. 2007). The efficacy of the extracts in the reaction with DPPH correlated well with the amount of cichoric acid present in the various extracts. The alkamides alone showed no antioxidant activity in any of the tests. Alkamides present in the extract increased, however, the antioxidative effect of cichoric acid in the peroxidation lipid emulsion assay. Antioxidant activity in terms of TEAC (μ M trolox/100 g DW) of *E. purpurea* leaves reported was 12.3 μ M for ABTS, 75 μ M for DPPH and 94.6 μ M for FRAP (ferric reducing antioxidant power) assays (Wojdyło et al. 2007). Total phenolic contents reported were 15.15 mg GAE/100 g DW. The DPPH scavenging reached 93.6 %, and the values of EC_{50} were (34.16) μ g/ml and (65.48) μ g/ml for the extracts obtained by the classical and ultrasound extractions, respectively (Stanisavljević et al. 2009).

At level of 10 μ g/ml, the scavenging abilities of tested samples on DPPH radicals were in the descending order of ascorbic acid>BHA (butylated hydroxyanisole)>flower extract> α -tocopherol (Tsai et al. 2011). At level of 30 μ g/ml, the flower extract and α -tocopherol showed 90.82 and 93.10 % scavenging abilities, respectively. The radical scavenging ability of *E. purpurea* flower extract could be attributable to the caffeic acid derivatives, especially cichoric acid with two adjacent hydroxyl groups of its phenolic rings showed the highest radical scavenging ability. The order of potency against DPPH radicals was the following: echinacoside>cichoric acid>chlorogenic acid>caffeic acid>caftaric acid. At the level of 100 μ g/ml, the reducing power of samples was in the descending order of ascorbic acid>BHA>flower extract> α -tocopherol. The ascorbic acid, BHA, and flower extract attained the same maximum reducing power (2.3 AU) at 100, 200 and 400 μ g/ml, respectively. The flower extracts exerted an 81.88 % ferrous ions chelating effect at 3 mg/ml concentration when compared with the EDTA (ethylenediaminetetraacetic acid) concentration of 10 μ g/ml.

Immunomodulatory Activity

Studies found that the main immunostimulatory activity of *Echinacea* resided in the water-soluble materials rather than the lipoidal small molecules (Pillai et al. 2007). The use of flow cytometry demonstrated a link between the polysaccharides in *Echinacea* and the biologic immunostimulatory effect. *E. purpurea*, *E. pallida* and *E. angustifolia* leaves, stems, flowering tops and roots all produced substantial immunostimulatory activity. In-vitro and in-vivo studies indicated that the therapeutic effects of *Echinacea* were due to a stimulation of cellular immune response (Mahady et al. 2001).

In-Vitro Studies

Purified polysaccharides (EPS) prepared from *Echinacea purpurea* were shown to strongly activate macrophages that developed pronounced extracellular cytotoxicity against tumour targets (Stimpel et al. 1984). The splenic lymphocytes from mice treated with *E. purpurea* and *Hypericum perforatum* at the two dose levels used (30 and 100 mg/kg/day) were shown to be significantly more resistant to apoptosis than those from mice treated only with the vehicle (Di Carlo et al. 2003). Further, mice treated with these natural substances showed a decrease in Fas-Ag expression and an increase in Bcl-2 expression.

The 4-*O*-methyl-glucuronarabinoxylan, isolated from *E. purpurea* showed immune-stimulating activity in several in-vitro immunological test systems (Wagner et al. 1984, 1985; Proksch and Wagner 1987). The fucogalactoxyloglucan of mean molecular weight 25,000 isolated from *E. purpurea* cell culture enhanced phagocytosis in vitro and in-vivo (Wagner et al. 1988). The arabinogalactan specifically stimulated macrophages to excrete the tumour necrosis factor (TNF). The arabinogalactan protein (AGP) from pressed juice of the aerial parts of *Echinacea purpurea* demonstrated binding to lymphocytes, monocytes and granulocytes of different donors (Thude et al. 2006). A high molecular weight arabinogalactan protein (AGP) from the pressed juice of *Echinacea purpurea*, known to exhibit

immunomodulatory properties in vitro, was characterized (Volk et al. 2007). Normal human peripheral blood macrophages cultured in concentrations of *Echinacea purpurea* fresh pressed juice as low as 0.012 µg/ml produced significantly higher levels of IL-1, TNF-α, IL-6 and IL-10 than unstimulated cells (Burger et al. 1997). The high levels of IL-1, TNF-α and IL-10 induced by very low levels of echinacea were consistent with an immune-activated antiviral effect. Echinacea induced lower levels of IL-6 in comparison to the other cytokines measured. Echinacea herb and root powders were found to stimulate murine macrophage cytokine secretion as well as to significantly enhance the viability and/or proliferation of human peripheral blood mononuclear cells in vitro (Rininger et al. 2000). In contrast, echinacea extracts chemically standardized to phenolic acid or echinacoside content and fresh pressed juice preparations were found to be inactive as immunostimulatory agents but did display, to varying degrees, antiinflammatory and antioxidant properties.

Studies showed that *E. purpurea* root and leaf-stem extract exhibited opposite (enhancing vs. inhibitory) modulatory effects on the expression of the CD83 marker in human dendritic cells (DCs) (Wang et al. 2006). Downregulation of mRNA expression of specific chemokines (e.g., CCL3 and CCL8) and their receptors (e.g., CCR1 and CCR9) was observed in stem- and leaf-treated DCs. Other chemokines and regulatory molecules (e.g., CCL4 and CCL2) involved in the c-Jun pathway were found to be upregulated in root-treated DCs. In another study, following 48 hours exposure of dendritic cells from C57Bl/6 mice to *E. purpurea* root and leaf extracts, it was found that the polysaccharide-rich root extract increased the expression of MHC class II, CD86 and CD54 surface biomarkers whereas the alkylamide-rich leaf extract inhibited expression of these molecules (Benson et al. 2010). Production of IL-6 and TNF-α increased in a concentration-dependent manner with exposure to the root, but not leaf, extract. In contrast, the leaf but not root extract inhibited the enzymatic activity of cyclooxygenase-2. The leaf but not

root extract inhibited the antigen-specific activation of naïve CD4⁺ T cells from OT II/Thy1.1 mice. These results suggested that *E. purpurea* could be immunostimulatory, immunosuppressive and/or antiinflammatory depending on the plant part and extraction method.

E. purpurea extracted in a solvent mixture of 95:5 ethanol/water dose-dependently inhibited interleukin IL-2 production in human Jurkat T cells (Sasagawa et al. 2006). This IL-2 inhibitory activity correlated with the presence of alkylamides but not caffeic acid derivatives. *E. purpurea* extract was both IL-2 suppressive and cytotoxic at 50 and 100 µg/ml. Lower concentrations from 6.25 to 25 µg/ml significantly decreased IL-2 production, but not cell viability. Alkylamides at concentrations found in a 50 µg/ml extract decreased IL-2 production by approximately 50 %, but not cell viability in a dose-dependent manner. *Echinacea* and several of its phytochemical components were found to have opposing effects on NFκB expression by Jurkat cells (a human T-cell line) (Matthias et al. 2008). In the absence of stimulation, *Echinacea* and its components exerted no significant effect on basal NFκB expression levels. In the presence of endotoxin (LPS), NFκB expression was decreased. However, this decrease was significantly reversed by treatment with cichoric acid, an *Echinacea* root extract (prepared from both *Echinacea angustifolia* and *Echinacea purpurea*) and the alkylamide fraction derived from this combination. For the phorbol myristate acetate stimulation of Jurkat cells, effects on NFκB expression were mixed. Depending on the concentration, cichoric acid and a 2,4-diene alkylamide significantly induced NFκB levels, whereas a 2-ene alkylamide caused a significant inhibition. In contrast, both the *Echinacea* and the mixed alkylamide fraction exerted no effect.

Pugh et al. (2012) found that differences in total bacterial load within *Echinacea purpurea* samples were strongly correlated with in-vitro macrophage activity (NF-κB activation in THP-1 cells) and content of bacterial lipopolysaccharides in the extracts. The results added to the growing body of evidence that bacteria within *Echinacea* were the main source of components

responsible for enhancing innate immune function.

Animal Studies

Polysaccharides purified from large-scale *Echinacea purpurea* plant cell cultures were found to activate human phagocytes in vitro and in vivo and to induce acute-phase C reactions (Roesler et al. 1991b). These substances enhanced the spontaneous motility of polymorphonuclear leukocytes (PMN) under soft agar and increased the ability of these cells to kill staphylococci. Monocytes were activated to secrete tumour necrosis factor alpha (TNF-α) and interleukins IL-6 and IL-1, whereas class II expression was unaffected. Intravenous application of the polysaccharides to test subjects immediately induced a fall in the number of PMN in the peripheral blood, indicating activation of adherence to endothelial cells. This decline was followed by a leukocytosis due to an increase in the number of PMN and a lesser increase of monocytes. The acute-phase C-reactive protein (CRP) was induced, probably due to activation of monocytes and macrophages to produce IL-6. Subsequent in-vivo studies found that the purified polysaccharides (EP) from *Echinacea purpurea* plant cell cultures enhanced mice phagocytes' activities thus protecting against systemic infections with *Listeria monocytogenes* and *Candida albicans* (Roesler et al. 1991a). They confirmed their hypothesis that macrophages (Mφ) from different organ origin could be activated to produce IL-1, TNFα and IL-6 to produce elevated amounts of reactive oxygen intermediates and to inhibit growth of *Candida albicans* in-vitro and that in-vivo the substances could induce increased proliferation of phagocytes in spleen and bone marrow and migration of granulocytes to the peripheral blood. In a subsequent study, EP was found effective in activating peritoneal macrophages isolated from animals after administration of cyclophosphamide (CP) or cyclosporin A (CsA) (Steinmüller et al. 1993). EP-treated macrophages exhibited increased production of tumour necrosis factor-alpha (TNF) and enhanced cytotoxicity against tumour target WEHI 164 as well as against the intracellular parasite

Leishmania enrietti. After a CP-mediated reduction of leukocytes in the peripheral blood, the polysaccharides induced an earlier influx of neutrophil granulocytes as compared to PBS (phosphate buffer saline)-treated controls. EP treatment of mice, immunosuppressed with CP or CsA, restored their resistance against lethal infections with the predominantly macrophage-dependent pathogen *Listeria monocytogenes* and predominantly granulocyte-dependent *Candida albicans*.

The results of studies suggested that oral gavage with *Echinacea* preparations containing optimal concentrations of cichoric acid, polysaccharides and alkylamides were potentially effective in stimulating an in-vivo, nonspecific immune response in normal male Sprague–Dawley rats (Goel et al. 2002a, b). Among the components the alkylamides at the dose level of 12 µg/kg body weight/day significantly increased the phagocytic activity as well as phagocytic index of the alveolar macrophages. The alveolar macrophages obtained from this alkylamide-administered group also produced significantly more TNF-α and nitric oxide after an in-vitro stimulation with LPS than any other active component or the control. The immunomodulatory effects of alkylamides appeared to be more pronounced in lungs than in spleen. Studies demonstrated *Echinacea purpurea* extracts to be potent activators of natural killer (NK) cells cytotoxicity (Gan et al. 2003). NK cytotoxicity was augmented 100 % at the concentration of 0.1 µg/ml of *Echinacea* in a short time (4-hour) assay. *Echinacea* augmented the frequency of NK target conjugates and activated the programming for lysis of NK cells. In another study, dietary administration of *E. purpurea* (14 days) to aging, normal mice or thyroxin injection revealed that *E. purpurea*, but not thyroxin, had the capacity to increase natural killer (NK) cell numbers, in aging mice, reflecting increased new NK cell production in their bone marrow generation site, leading to an increase in the absolute numbers of NK cells in the spleen, their primary destiny (Currier and Miller 2009). The *E. purpurea*-mediated increase in NK cell numbers was also paralleled by an increase in their antitumour, cytolytic functional capacity. In a recent study levamisole and *Echinacea*

purpurea separately and together exerted a stimulant effect on the immune system in rats (Sadigh-Eteghad et al. 2011). The gamma globulin level, white blood cells, neutrophil and monocyte counts and phagocyte activity increased significantly in comparison with normal saline group during the study. In the group that received *Echinacea* and levamisole simultaneously, these effects were synergistically increased.

Male rats were orally treated with two different doses (30 and 100 mg/kg) of extract of *Echinacea purpurea* (EP), *Hypericum perforatum* (HP) and *Eleutherococcus senticosus* (ES) drugs for 3 or 15 days (Di Carlo et al. 2005). A 3-day treatment was not able to modify prolactin serum levels, whereas a 15-day treatment with EP and HP at the higher dose significantly inhibited prolactin production; prolactin had been reported to play an important role in immune system regulation. The treatment with ES was ineffective. They suggested that a possible mechanism for this effect could be that both *Echinacea purpurea* and *Hypericum perforatum* extracts displayed a direct dopaminergic activity, although an involvement of the GABAergic system could not be excluded.

Clinical Studies

Year-and-a-half old, dried *Echinacea* roots were found to retain cytokine-modulating capabilities in an in-vitro human older adult model of influenza vaccination (Senchina et al. 2006). In this model, peripheral blood mononuclear cells were collected from subjects 6 months postvaccination and stimulated in vitro with the two type A influenza viruses contained in the trivalent 2004–2005 vaccine with a 50 % alcohol tincture prepared from the roots of one of seven *Echinacea* species: *E. angustifolia*, *E. pallida*, *E. paradoxa*, *E. purpurea*, *E. sanguinea*, *E. simulata* and *E. tennesseensis*. Four species (*E. angustifolia*, *E. purpurea*, *E. simulata*, *E. tennesseensis*) augmented interleukin IL-10 production, diminished IL-2 production, and had no effect on interferon IFN-γ production. Parnham (1996) reported squeezed sap of *E. purpurea*, widely used in self-medication, to be well tolerated on long-term oral administration with no adverse

event in healthy adults. In contrast, parenteral administration of the squeezed sap of *E. purpurea* (Echinacin®) may be associated with symptoms of immunostimulation (shivering, fever, muscle weakness). Echinacin® had little or no effect on lymphocyte responses but had been reported to cause transient lymphopenia in some patients with infections of various etiologies. In a double-blind placebo-controlled crossover design study with two treatment periods of 14 days involving 40 healthy male volunteers (age range 20–40 years), oral administration of *Echinacea purpurea* pressed juice for 1 and 2 weeks had only minor effects on two out of 12 lymphocyte subpopulations determined in the study (Schwarz et al. 2005). The small differences observed in the number of CD8+T lymphocytes and natural killer cells were only of questionable physiological relevance.

Echinacea purpurea was found to have immunomodulatory property. Ritchie et al. (2011) found that a subgroup of volunteers who showed low pretreatment levels of the cytokines MCP-1, IL-8, IL-10 or IFN- γ ($n=8$) showed significant stimulation of these factors upon Echinaforce® treatment (*E. purpurea*) (30–49 % increases), whereas the levels in subjects with higher pretreatment levels remained unaffected. Volunteers who reported high stress levels ($n=7$) and more than 2 colds per year experienced a significant transient increase in interferon IFN- γ upon Echinaforce® treatment (>50 %). Subjects with low cortisol levels ($n=11$) showed significant downregulation of the acute-phase proteins interleukin IL1- β , IL-6, IL-12 and TNF- α by Echinaforce® (range, 13–25 %), while subjects with higher cortisol levels showed no such downregulation. The authors concluded that Echinaforce® thus regulated the production of chemokines and cytokines according to current immune status, such as responsiveness to exogenous stimuli, susceptibility to viral infection and exposure to stress.

Review Studies

In a review of immunomodulatory efficacy of preparations containing extracts of *Echinacea*, 26 controlled clinical trials (18 randomized, 11 dou-

ble blind) were identified by Melchart et al. (1994). Their study indicated that preparations containing extracts of *Echinacea* could be efficacious immunomodulators. However, present evidence was still insufficient for clear therapeutic recommendations as to which preparation to use and which dose to employ for a specific indication.

Antiviral Activity

The roots of *E. purpurea* were found to induce a substance showing interferon-like activity (Skwarek et al. 1996). Biological activity studies showed that the protective titre (the largest dilution which protected cells by 50 % against virus infection) of the interferon-like materials was 1:6–1:15. *Echinacea purpurea* and *Panax ginseng* extracts at concentrations ≥ 0.1 or 10 $\mu\text{g/kg}$, respectively, significantly enhanced natural killer cell function against human erythromyeloblastoid leukaemia cell line, K562 cells in healthy subjects and chronic fatigue syndrome or acquired immunodeficiency syndrome (AIDS) patients (See et al. 1997). Similarly, the addition of either herb significantly increased antibody-dependent cellular cytotoxicity (ADCC) against human herpesvirus 6 infected H9 cells of peripheral blood mononuclear cells (PBMC) from all subject groups. Thus, extracts of *Echinacea purpurea* and *Panax ginseng* enhanced cellular immune function of PBMC both from normal individuals and patients with depressed cellular immunity. Extracts of 8 taxa of the genus *Echinacea* were found to have antiviral activity against herpes simplex (HSV) virus type I in vitro when exposed to visible and UVA light (Binns et al. 2002a). *n*-Hexane extracts of roots containing alkenes and amides were more active in general than ethyl acetate extracts containing caffeic acids. *Echinacea purpurea n*-hexane root extract (MIC=0.12 mg/ml) was one of the most potent inhibitors of HSV.

Aqueous extracts of *E. purpurea* root contained a relatively potent activity against herpes simplex virus (HSV) and influenza virus (FV) but not against rhinovirus (RV) (Hudson et al. 2005).

These fractions had low amounts of caffeic acids and alkalamides. The ethyl acetate fraction contained significant but weak activity against both HSV and FV and contained significant levels of cichoric acid. All aqueous fractions of *E. purpurea* aerial parts contained potent activity against herpes simplex virus and influenza virus (Vimalanathan et al. 2005). The antiviral activity could partly be attributed to polysaccharide and cichoric acid components; their individual contributions could not account for the total antiviral activity. Additionally, the ethanol- and ethyl acetate-soluble fractions from leaves and stem contained an uncharacterized but potent antiviral photosensitizer, which was absent from the flower extract. None of the fractions, however, contained anti-rhinovirus.

Studies showed that exposure of a cultured line of human bronchial epithelial cells to rhinovirus 14 infection stimulated the release of at least 31 cytokine-related molecules, including several important chemokines known to attract inflammatory cells. Most of these effects were reversed by simultaneous exposure to either of the two *Echinacea* extracts (Sharma et al. 2006a). Rhinovirus infection of BEAS-2B cell line resulted in a more dramatic increase in multiple transcription factors including proinflammatory factors examined, such as NFkB, AP-1, AP-2 and STATs 1–6 (Sharma et al. 2006b). However, when rhinovirus-infected cells were treated with either of the two *Echinacea* extracts, transcription factors levels were reduced to low levels, although the pattern of the reductions was different for the two extracts. The results could help to explain the beneficial effects of *Echinacea* consumption. All the viruses tested, rhinoviruses 1A and 14, influenza virus, respiratory syncytial virus, adenovirus types 3 and 11, and herpes simplex virus type 1, induced substantial secretion of IL-6 and IL-8 (CXCL8), in addition to several other chemokines, in a line of human bronchial epithelial cells (BEAS-2B) (Sharma et al. 2009). In every case, however, *Echinacea* (Echinaforce, an ethanol extract of herb and roots of *E. purpurea*) inhibited this induction. The *Echinacea* preparation also showed potent virucidal activity against viruses with membranes, indicating the

multifunctional potential of the herb. The results supported the concept that certain *Echinacea* preparations could alleviate ‘cold and flu’ symptoms, and possibly other respiratory disorders, by inhibiting viral growth and the secretion of proinflammatory cytokines.

In a separate in-vitro study, human H1N1-type IV, highly pathogenic avian IV (HPAIV) of the H5- and H7-types, as well as swine origin IV (S-OIV, H1N1) were all inactivated in cell culture assays by the *Echinacea purpurea* (Echinaforce®, EF) preparation at concentrations ranging from the recommended dose for oral consumption to several orders of lower magnitude (Pleschka et al. 2009). Detailed studies with the H5N1 HPAIV strain indicated that direct contact between EF and virus was required, prior to infection, in order to obtain maximum inhibition in virus replication. Hemagglutination assays showed that the extract inhibited the receptor-binding activity of the virus, suggesting that the extract interferes with the viral entry into cells. Recent studies reported that Echinaforce® the standardized extract of *Echinacea purpurea* exhibited immunomodulation and broad antiviral effects against respiratory tract viruses (Schapowal 2012). Haemagglutinin and neuraminidase were blocked. In contrast to Oseltamivir no resistance was caused by Echinaforce®. A randomized, double-blind, placebo-controlled study over 4 months confirmed that Echinaforce® supported the immune resistance and acted directly against a series of viruses. He reported Echinaforce® to be efficacious and safe in respiratory tract infections for long-term and short-term prevention as well as for acute treatment.

An open-label, fixed-sequence study of 15 HIV-infected patients showed that co-administration of *E. purpurea* root extract containing capsules with etravirine (a nonnucleoside reverse transcriptase inhibitor of HIV) was safe and well tolerated in HIV-infected patients (Moltó et al. 2012). The geometric mean ratio for etravirine coadministered with *E. purpurea* relative to etravirine alone was 1.07 for the maximum concentration, 1.04 for the area under the concentration-time curve from 0 to 24 hours

and 1.04 for the concentration at the end of the dosing interval. The data suggested that no dose adjustment for etravirine was necessary.

Rhinoviruses, influenza viruses, herpes viruses and calcivirus were found to be susceptible to *E. purpurea* ethanol extract and aqueous extract; respiratory syncytial virus, coronavirus (mouse) were susceptible only to *E. purpurea* ethanol extract, and polio virus was not susceptible to both extracts (Hudson et al. 2005; Vimalanathan et al. 2005; Pleschka et al. 2009; Hudson 2012).

Echinacea and Respiratory Tract Infection

In-Vitro Studies

A standardized *Echinacea* extract (Echinaforce) was found to have dual action against several important respiratory bacteria, a killing effect and an antiinflammatory effect (Sharma et al. 2010). It readily inactivated *Streptococcus pyogenes*, often associated with sore throat and more severe pulmonary infections, *Haemophilus influenzae* and *Legionella pneumophila*, and reversed their proinflammatory responses. *Staphylococcus aureus* (methicillin-resistant and sensitive strains) and *Mycobacterium smegmatis* were less sensitive to the bactericidal effects of *Echinacea* however, but their proinflammatory responses were still completely reversed. In contrast some other pathogens tested, including *Candida albicans*, were relatively resistant. The results supported the concept of using a standardized *Echinacea* preparation to control symptoms associated with bacterial respiratory infections.

The alkylamides undeca-2Z,4E-diene-8,10-diynic acid isobutylamide, dodeca-2E,4E,8Z,10E/Z-tetraenoic acid isobutylamide, dodeca-2E,4E-dienoic acid isobutylamide, and undeca-2E-ene-8,10-diynoic acid isobutylamide from *E. purpurea* suppressed production of TNF- α and PGE2 from RAW 264.7 macrophage-like cells infected with the H1N1 influenza A strain PR/8/34 (Cech et al. 2010). Dodeca-2E,4E-dienoic acid isobutylamide was especially effective at inhibiting production of these mediators

and also strongly inhibited production of G-CSF, CCL2/MCP-1, CCL3/MIP-1 α and CCL5/RANTES. In contrast, the ethanol extracts (75 %), prepared from *E. purpurea* dormant roots, displayed a range of effects from suppression to stimulation of mediator production. Analysis of the extracts revealed slight variations in concentration of alkylamides, caftaric acid and cichoric acid, but the activity of the extracts did not strongly correlate with concentrations of these compounds. The in-vitro studies suggested *E. purpurea* extracts to have the potential for use in alleviating the symptoms and pathology associated with infections with influenza A.

Clinical/Human Studies

Some herbal preparations, including *Echinacea purpurea*, had been reported to improve cold symptoms in adults but ineffective in children (Fashner et al. 2012). Randolph et al. (2003) found that the overall gene expression pattern at 48 hours to 12 days after taking *Echinacea* product for cold and flu by six healthy nonsmoking subjects (18–65 years of age) was consistent with an antiinflammatory response. The expression of interleukin-1 beta, tumour necrosis factor-alpha, intracellular adhesion molecule and interleukin-8 was modestly decreased up through day 5, returning to baseline by day 12. The expression of interferon-alpha steadily rose through day 12, consistent with an antiviral response. The data presented a gene expression response pattern that was consistent with *Echinacea*'s reported ability to reduce both the duration and intensity of cold and flu symptoms.

Mixed results have been obtained in clinical studies on the efficacy of *E. purpurea* in combating respiratory tract infections. In a randomized, double-blind, placebo-controlled study, 246 of 559 recruited healthy, adult volunteers contracted a common cold and took 3 times daily 2 tablets of either Echinaforce® (*Echinacea purpurea* preparation from 95 % herba and 5 % radix), *Echinacea purpurea* concentrate (same preparation at 7 times higher concentration), special *Echinacea purpurea* radix preparation (totally different from that of Echinaforce®) or placebo until they felt healthy again but not longer than 7 days

(Brinkeborn et al. 1999). It was found that Echinaforce® and its concentrated preparation were significantly more effective than the special *Echinacea* extract or placebo. All treatments were well tolerated. Among the *Echinacea* groups the frequency of adverse events was not significantly higher than in the placebo group. They concluded that *Echinacea* concentrate as well as Echinaforce® represented a low-risk and effective alternative to the standard symptomatic medicines in the acute treatment of common cold.

In a randomized, double-blind, placebo-controlled trial, 282 subjects aged 18–65 years, a total of 128 subjects contracted a common cold (59 echinacea, 69 placebo) (Goel et al. 2004). The total daily symptom scores were found to be 23.1 % lower in the echinacea group than in placebo in those who followed all elements of the study protocol. Throughout the treatment period, the response rate to treatments was greater in the echinacea group. A few adverse event profiles were observed in both groups. The researchers concluded that early intervention with a standardized formulation of echinacea resulted in reduced symptom severity in subjects with naturally acquired upper respiratory tract infection. In a clinical study, Echinilin (a formulation prepared from freshly harvested *Echinacea purpurea* plants and standardized on the basis of three known active components: alkamides, cichoric acid and polysaccharides) or placebo was administered to volunteers at the onset of their cold for a period of 7 days, with eight doses (5 ml/dose) on day 1 and three doses on subsequent days (Goel et al. 2005). The decrease in total daily symptomatic score was more evident in the echinacea group than in the placebo group. These effects of echinacea were associated with a significant and sustained increase in the number of circulating total white blood cells, monocytes, neutrophils and natural killer cells. In the later part of the cold, the echinacea treatment suppressed the cold-related increase in superoxide production by the neutrophils. The results suggested that Echinilin, by enhancing the nonspecific immune response and eliciting free radical scavenging

properties, may have led to a faster resolution of the cold symptoms.

Jawad et al. (2012) conducted a 4-month randomized, double-blind, placebo-controlled trial to investigate the safety (risk) and efficacy (benefit) of *Echinacea purpurea* (95 % herba and 5 % root) extract in the prevention of common cold episodes with 755 healthy subjects. *Echinacea* extract found to reduce the total number of cold episodes, cumulated episode days within the group, and painkiller-medicated episodes. *Echinacea* inhibited virally confirmed colds and especially prevented enveloped virus infections. *Echinacea* showed maximal effects on recurrent infections, and preventive effects increased with therapy compliance and adherence to the protocol. A total of 293 adverse events occurred with echinacea and 306 with placebo treatment. Nine and 10 % of participants experienced adverse events, which were at least possibly related to the study drug (adverse drug reactions). Thus, the safety of *Echinacea* was noninferior to placebo. The study concluded that compliant prophylactic intake of *E. purpurea* over a 4-month period appeared to provide a positive risk to benefit ratio.

In a randomized, placebo-controlled, double-blind study, treatment with fluid extract of *Echinacea purpurea* (widely used for the prevention and treatment of colds and respiratory infections), did not significantly decrease the incidence, duration or severity of colds and respiratory infections compared to placebo (Grimm and Müller 1999). During the 8-week treatment period, 35 (65 %) of 54 patients in the echinacea group and 40 (74 %) of 54 patients in the placebo group had at least one cold or respiratory infection. The average number of colds and respiratory infections per patient was 0.78 in the echinacea group, and 0.93 in the placebo group. There were no significant differences between treatment groups in the number of infections in each category of severity. Side effects were observed in 11 patients (20 %) of the echinacea group and in seven patients (13 %) of the placebo group. In a randomized, double-blind placebo-controlled trial of 175 adults travelling back from Australia to America, Europe or Africa for a period of 1–5 weeks on commercial flights via

economy class, supplementation with standardized *Echinacea* tablets, taken before and during travel, may have preventive effects against the development of respiratory symptoms during travel involving long-haul flights (Tiralongo et al. 2012). In another study, 128 patients were enrolled within 24 hours of cold symptom onset in a randomized, double-blind, placebo-controlled design wherein patients received either 100 mg of *E. purpurea* (freeze-dried pressed juice from the aerial portion of the plant) or a lactose placebo 3 times daily until cold symptoms were relieved or until the end of 14 days, whichever came first (Yale and Liu 2004). No statistically significant difference was observed between treatment groups for either total symptom scores or mean individual symptom scores. The time to resolution of symptoms was not statistically different. The efficacy of *E. purpurea* in reducing common cold was not confirmed.

In a multicenter randomized placebo controlled trial, *Echinacea purpurea* was found ineffective for treating upper respiratory tract infections in children aged 2–11 years (Mainous 2004). There was no significant difference in duration or severity of symptoms with *Echinacea purpurea* compared with placebo in children with upper respiratory tract infection. In another randomized, double-blind, placebo-controlled trial of 407 children aged 2–11 years including 337 upper respiratory tract infections (URIs) treated with echinacea and 370 with placebo, *Echinacea purpurea* was found not effective in treating URI symptoms in these children, and its use was associated with an increased risk of rash (Taylor et al. 2003).

Review Studies

Scoop et al. (2006) conducted a meta-analysis on the therapeutic effectiveness of *Echinacea* in the treatment and the prevention of colds, wherein 3 suitable studies were selected for pooling of data, and 231 were excluded from the analysis because they related to studies of spontaneous common colds. The meta-analysis suggested that standardized extracts of *Echinacea* were effective in the prevention of symptoms of the common cold after clinical inoculation, compared with placebo. However, more prospective, appropriately

structured clinical studies were required to confirm. Although *Echinacea* preparations tested in clinical trials differed greatly, there was some evidence that preparations based on the aerial parts of *Echinacea purpurea* might be effective for the early treatment of colds in adults but results were not fully consistent (Linde et al. 2006). Beneficial effects of other *Echinacea* preparations and for preventative purposes might exist but had not been shown in independently replicated, rigorous, randomized trials. A meta-analysis of 14 studies provided published evidence supporting *Echinacea*'s benefit in decreasing the incidence and duration of the common cold (Shah et al. 2007). Woelkart et al. (2008) stated that *Echinacea* preparations were more effective than no treatment, more effective than placebo or similarly effective to other treatments in the prevention and the treatment of the common cold. In a more recent review on the efficacy of *Echinacea* in cold prevention, Hart and Dey (2009) reiterated that in view of the residual uncertainty and the gaps between the evidence and the ways that this was summarized on webpages, it may prove difficult for consumers to assimilate the evidence. As well as undertaking high-quality trials in complementary medicine, there was a need to ensure precision in the reporting of uncertainty.

Antimicrobial Activity

Echinacea (including *E. purpurea*) were found to have phototoxic antimicrobial activity against fungi, including clinically relevant pathogenic fungi. Results showed that hexane extracts of *Echinacea* variably inhibited growth of yeast strains of *Saccharomyces cerevisiae*, *Candida shehata*, *C. kefyr*, *C. albicans*, *C. steatulytica* and *C. tropicalis* under near UV irradiation (phototoxicity) and to a lower extent without irradiation (conventional antifungal activity) (Binns et al. 2000). The presence of polyacetylenes and alkylamides in extracts of different organs was confirmed in *Echinacea purpurea* and was related to phototoxic activity. Significant phototoxicity was demonstrated by pure

trideca-1-ene-3,5,7,9,10-pentayne from *E. purpurea* roots, while only minor phototoxicity was induced by the other two *E. purpurea* acetylenic compounds undeca-2*E*,4*Z*-diene-8,10-dienoic acid isobutylamide and dodeca-2*E*,4*E*,8*Z*,10*E/Z*-tetraenoic acid isobutylamide. Phototoxic activity of *Echinacea* spp. was primarily attributed to the ketoalkenes and ketoalkynes abundantly present in the roots. Root extracts of the eight *Echinacea* species including *E. purpurea* showed antifungal activity against most of the pathogenic fungi (*Trichophyton tonsurans*, *T. mentagrophytes*, *Microsporium gypseum*, *Pseudallescheria boydii*, *Cryptococcus neoformans* and two *Candida albicans* isolates) (Merali et al. 2003). Recent studies on *Echinacea purpurea* had revealed that certain standardized preparations contain potent and selective antiviral and antimicrobial activities (Hudson 2012). In addition, they displayed multiple immunomodulatory activities, comprising stimulation of certain immune functions such as phagocytic activity of macrophages and suppression of the proinflammatory responses of epithelial cells to viruses and bacteria, which are manifested as alterations in secretion of various cytokines and chemokines. *E. purpurea* dried aerial part ethanol extract showed a considerable growth inhibition on *Candida albicans* and *Saccharomyces cerevisiae*, while no growth inhibition zones were observed for *Aspergillus niger* (Stanisavljević et al. 2009). In-vitro studies showed a standardized preparation of *Echinacea purpurea* (Echinaforce®) could provide a safe twofold benefit to acne individuals by inhibiting proliferation of the Gram-positive bacterium *Propionibacterium acnes* and reversing the bacterial-induced inflammation (Sharma et al. 2011). *E. purpurea* completely reversed the bacterial increase in secretion of substantial amounts of several proinflammatory cytokines, including IL-6 and IL-8 (CXCL8), and brought the cytokine levels back to normal.

Antiinflammatory Activity

Root extracts of the three commercial species of *Echinacea* (*E. purpurea*, *E. pallida* var.

angustifolia, *E. pallida* var. *pallida*) inhibited the 5-lipoxygenase (5-LOX) enzyme (Merali et al. 2003). The results show that *Echinacea* spp. had significant antiinflammatory activity. Alcohol extracts of *Echinacea angustifolia*, *Echinacea pallida* and *Echinacea purpurea* significantly inhibited NO production by lipopolysaccharide (LPS)-activated the RAW 264.7 macrophage cell line (Zhai et al. 2009). Arginase activity of RAW 264.7 cells stimulated with 8-bromo-cAMP was significantly increased by alcohol extracts of all three *Echinacea* species. The polar fraction containing caffeic acid derivatives enhanced arginase activity, while the lipophilic fraction containing alkamides exhibited a potential of inhibiting NO production and iNOS expression. The results suggested that the antiinflammatory activity of *Echinacea* might be due to multiple active metabolites, working together to switch macrophage activation from classical activation towards alternative activation.

At 100 g/ml, several *E. purpurea* alkamides, isolated from *E. purpurea* roots, inhibited cyclooxygenase COX-I and COX-II enzymes in the range of 36–60 % and 15–46 %, respectively, as compared to controls (Clifford et al. 2002). Chicca et al. (2009) demonstrated that ethanol *E. purpurea* radix and herba extracts elicited synergistic pharmacological effects on the endocannabinoid system in vitro. Supra-additive action of *N*-alkylamide combinations was observed at the level of intracellular calcium release as a function of cannabinoid receptor type-2 (CB₂) activation. Likewise, synergism of the radix and herba tinctures was observed in LPS-stimulated cytokine expression from human PBMCs. While the expression of the antiinflammatory cytokine IL-10 was significantly superstimulated, the expression of the proinflammatory TNF- α protein was inhibited more strongly upon combination of the extracts. They concluded that *N*-alkylamides in the extracts acted in concert to exert pleiotropic effects modulating the endocannabinoid system by simultaneously targeting the CB₂ receptor, endocannabinoid transport and degradation. Cannabinoid type-1 (CB₁) and CB₂ receptors belong to the family of G protein-coupled receptors and are the primary targets of

the endogenous cannabinoids *N*-arachidonoyl ethanolamine and 2-arachidonoyl glycerol (Gertsch et al. 2006). CB₂ receptors are believed to play an important role in distinct pathophysiological processes, including metabolic dysregulation, inflammation, pain and bone loss.

A mitogen-induced murine skin inflammation study suggested that alkamides were the active antiinflammatory components present in *Echinacea* plants (Hou et al. 2010). Mixed alkamides and the major component, dodeca-2*E*,4*E*,8*Z*,10*Z*(*E*)-tetraenoic acid isobutylamides (8/9), were then isolated from *E. purpurea* root extracts for further bioactivity elucidation. In macrophages, the alkamides significantly inhibited cyclooxygenase 2 (COX-2) activity and the lipopolysaccharide-induced expression of COX-2, inducible nitric oxide synthase and specific cytokines or chemokines [i.e., TNF- α , interleukin (IL)-1 α , IL-6, MCP-1, MIP-1 β] but elevated heme oxygenase-1 protein expression. Cichoric acid, however, exhibited little or no effect. In another study, three alkamides and nitidanin diisovalerianate were identified, together with 14 known alkamides and one sesquiterpene from the roots of *Echinacea purpurea* (Hohmann et al. 2011). Their interaction with G-protein-coupled cannabinoid receptors was examined on rat brain membrane preparations. Both partial and inverse agonist compounds for cannabinoid (CB₁) receptors were identified among the metabolites, characterized by weak to moderate interactions with the G-protein signalling mechanisms. Upon co-administration with arachidonoyl-2'-chloroethylamide, a number of them proved capable of inhibiting the stimulation of the pure agonist, thereby demonstrating cannabinoid receptor antagonist properties. In an earlier study, alkylamides, anandamide and SR144528 were found to potently inhibit lipopolysaccharide-induced inflammation in human whole blood and exerted modulatory effects on cytokine expression, but these effects were not exclusively related to CB₂ binding (Raduner et al. 2006). The alkylamides dodeca-2*E*,4*E*,8*Z*,10*Z*-tetraenoic acid isobutylamide (A1) and dodeca-2*E*,4*E*-dienoic acid isobutylamide (A2) bound to the CB₂ receptor more strongly than the endogenous cannabinoids. A1,

A2, anandamide, the CB₂ antagonist SR144528 (K_i < 10 nM), and also the non-CB₂-binding alkylamide undeca-2*E*-ene,8,10-diynoic acid isobutylamide all significantly inhibited lipopolysaccharide-induced tumour necrosis factor alpha, IL-1beta and IL-12p70 expression (5–500 nM) in a CB₂-independent manner.

Anticancer Activity

Animal studies found that dietary administration with *E. purpurea* preparations significantly decreased prostate weight of rats and increased lymphocyte numbers after 8 weeks (Skaudickas et al. 2003). *Echinacea purpurea* root hexane extract reduced cell viability of human pancreatic cancer MIA PaCa-2 and colon cancer COLO320 cell lines in a concentration- and time-dependent in vitro (Chicca et al. 2007). *E. purpurea* flower extract and cichoric acid significantly inhibited proliferation in a dose- and time-dependent manner human colon cancer cells Caco-2 and HCT-116 (Tsai et al. 2012). Cichoric acid treatment decreased telomerase activity in HCT-116 cells. Further, cichoric acid effectively induced apoptosis in colon cancer cells, which were characterized by DNA fragmentation, activation of caspase-9, cleavage of PARP and downregulation of β -catenin.

Anti-teratogenic Activity

Studies found that *E. purpurea* could stimulate immune system of mice more than levamisole and had better prophylactic effect against the teratogenic effect of phenytoin as evidenced by lower incidence of phenytoin-induced cleft palate, but it was not significant (Mahabady et al. 2006). Cleft palate incidence was 16, 5.3 and 3.2 % in fetuses of mice that received only phenytoin, phenytoin with levamisole, and phenytoin with *Echinacea* extract, respectively. Mean weight and length of fetuses of animals that received levamisole and *Echinacea* extract were significantly greater than those that received only phenytoin.

Hepatoprotective Activity

Studies showed that dodeca-2*E*,4*E*,8*Z*,10*Z*(*E*)-tetraenoic acid isobutylamides (Alk-8/9), isolated from *Echinacea purpurea* roots, dose-dependently induced heme oxygenase (HO)-1 protein expression in lipopolysaccharide-stimulated murine macrophages that was likely regulated by the JNK-mediated pathway through increasing SAPK/JNK phosphorylation, c-Jun protein expression, and phosphorylation and transcription factor AP-1 binding consensus DNA activity (Hou et al. 2011). Further, Alk-8/9 markedly induced c-Jun and HO-1 protein expression and suppressed serum aminotransferase activities, TNF- α expression, and hepatocyte damage in liver tissues of lipopolysaccharide/D-galactosamine-treated mice. The results suggested a potential application of *Echinacea*, a top-selling herbal supplement, as a hepatoprotective agent.

Antimutagenic Activity

The 50 % ethanol flower extract did not show toxicity and mutagenicity towards *Salmonella typhimurium* TA98 and TA100 with or without S9 mix (Tsai et al. 2011). The ethanol extract at 0.25–5 mg/plate exhibited a dose-dependent inhibitory effect against the mutagenicity of 2-aminoanthracene. They concluded that freeze-dried *E. purpurea* flower ethanol extract exhibited good antioxidant and antimutagenic activities.

Radioprotective Activity

E. purpurea administration significantly ameliorated the detrimental reduction effects of gamma rays on peripheral blood haemoglobin and the levels of red blood cells, differential white blood cells and bone marrow cells and antioxidant activity in mice (Aboueilella et al. 2007). The radioprotection effectiveness was similar to the radio recovery curativeness in comparison to the control group in most of the tested parameters.

The radioprotection efficiency was greater than the radio recovery in haemoglobin level during the first 2 weeks, in lymphoid cell count and thio-barbituric acid-reactive substances (TBARs) level at the fourth week and in superoxide dismutase (SOD) activity during the first 2 weeks, as compared to the levels of these parameters in the control group.

Actoprotective/Adaptogenic Activity

Purple coneflower tincture was found to improve both the work capacity and the endurance characteristics of white male mice in the conventional forced swim test (Kurkin et al. 2006). The actoprotective effect was attributed to a phenylpropanoid, echinacoside.

In a double-blind design placebo-controlled and self-administered study of 24 men (24.9 \pm 4.2 years) for 4 weeks, oral *Echinacea* supplementation resulted in significant increases in erythropoietin (EPO), VO₂max (maximal oxygen uptake) and running economy compared to placebo (Whitehead et al. 2012).

Anti-Tyrosinase Activity

Cichoric acid extracted from *E. purpurea* flowers was found to have significant tyrosinase inhibition activity in a broad range of concentration (10–20 mg/ml) (Jiang et al. 2012).

Trypanocidal Activity

Various *Echinacea* extracts could inhibit the proliferation of three species of trypanosomats: *Leishmania donovani*, *Leishmania major* and *Trypanosoma brucei* (Canlas et al. 2010). The standardized ethanol extract of *E. purpurea* (L.) Moench reversed the proinflammatory activity (production of cytokines IL-6 and IL-8) of *Leishmania donovani* in human bronchial epithelial cells and in human skin fibroblasts.

Larvicidal Activity

Several alkalamides isolated from *E. purpurea* roots exhibited mosquitocidal activity causing 100 % mortality of *Aedes aegypti* larvae (Clifford et al. 2002).

Herb–Drug/Herb–Herb Interaction Activity

Studies showed *Echinacea* alkylamides were degraded in a time- and NADPH-dependent manner in microsomal fractions suggesting they were metabolized by cytochrome P450 (P450) enzymes in human liver (Matthias et al. 2005b). There was a difference in the susceptibility of 2-ene and 2,4-diene pure synthetic alkylamides to microsomal degradation with (2*E*)-*N*-isobutylundeca-2-ene-8,10-diyamide metabolized to only a tenth the extent of (2*E*,4*E*,8*Z*,10*Z*)-*N*-isobutyldodeca-2,4,8,10-tetraenamide under identical incubation conditions. Alkylamide metabolites were detected and found to be the predicted epoxidation, hydroxylation and dealkylation products. These findings suggested that *Echinacea* may affect the P450-mediated metabolism of other concurrently ingested pharmaceuticals.

Cytochrome P450 enzymes (P450s) appeared to be the principal system responsible for the metabolism of *Echinacea* components and most of the main hepatic and some extrahepatic isoforms appeared to be involved (Toselli et al. 2009). Epoxide formation, N-dealkylation and hydroxylation were reported as the main metabolic pathways mediated by P450s and interactions with P450s determined the circulating concentrations and duration of action of these phytochemicals as well as any potential interactions with other chemicals. In-vivo studies in rats showed that *E. purpurea* may interact cytochrome P450 enzymes and induce significant herb–drug interactions which may alter pharmacotherapy (Mrozikiewicz, et al. 2010). The *Echinacea* ethanol extract could potentially inhibit the expression of CYP3A1 (41 %) and CYP3A2 (25 %) mRNAs. A weaker inhibitory effect was observed for CYP2D2 by 15 % and CYP2C6 by

18 % after long application of the *Echinacea* ethanol extract. CYP2D2 and CYP2C6 activities were also inhibited by extract but in a lesser degree than CYP3A1 activity. The findings suggested that *Echinacea* extract may influence the P450-mediated metabolism of different drugs and may initiate chemical carcinogenesis by activation of some compounds to their carcinogenic metabolites.

The multiherbal product Sambucus Force containing *Echinacea purpurea* and *Sambucus nigra* as its main constituents was found to inhibit CYP3A4 activity with IC₅₀ value of 1,192 (1,091–1,302) µg/ml (Schrøder-Aasen et al. 2012). The inhibitory potency appeared exclusively to be exerted by *E. purpurea*, implicating an insignificant inhibition by *S. nigra*. *Echinacea purpurea* acted differently in the multiherbal product, which showed a dual inhibition profile with both an uncompetitive (substrate-dependent) inhibition and a time-dependent (substrate-independent) inhibitory mechanism. These mechanistic differences were suggested to be caused by herb–herb interactions in the multiherbal product.

Allergy Problems

A woman with atopy experienced anaphylaxis after taking a commercial extract of *Echinacea*; hypersensitivity was confirmed by skin prick and RAST testing (Mullins 1998). Regular ingestion of *Echinacea* by up to 5 % of surveyed patients with atopy, combined with detection of *Echinacea*-binding IgE in atopic subjects (19 % by skin testing; 20 % with moderate to strong reactivity by RAST testing), indicated the possibility of severe allergic reactions, even with first-time use, due to cross-reactivity with other structurally similar allergens.

Toxicity and Safety Studies

According to the review of Huntley et al. (2005), despite the voluminous data availability on the efficacy of *Echinacea* (*Echinacea* spp. namely

E. angustifolia, *E. pallida* and *E. purpurea*), safety issues and the monitoring of adverse events had not been focused on. Short-term use of *Echinacea* was reported to be associated with a relatively good safety profile, with a slight risk of transient, reversible, adverse events. The major adverse events reported with *Echinacea* products are allergic reactions, ranging from contact dermatitis to anaphylaxis (Mahady et al. 2001). Patients with an allergy to plants in the daisy family (Asteraceae) should be instructed not to use products containing *Echinacea*. The use of *Echinacea* products during pregnancy and lactation would appear to be ill-advised in light of the paucity of data in this area. According to the review by Perri et al. (2006) there was good scientific evidence from a prospective cohort study that oral consumption of *Echinacea* during the first trimester did not increase the risk for major malformations. Low-level evidence based on expert opinion showed oral consumption of *Echinacea* in recommended doses to be safe for use during pregnancy and lactation. *Echinacea* was non-teratogenic when used during pregnancy. However more quality studies were needed to determine its safety.

After 4 weeks of oral administration of expressed juice of *E. purpurea* in doses amounting to many times, the human therapeutic dose laboratory tests and necropsy findings presented no evidence of any toxic effects in rats (Mengs et al. 1991). Tests for mutagenicity carried out in microorganisms and mammalian cells in-vitro and in mice all gave negative results. In an in-vitro carcinogenicity study, *E. purpurea* did not produce malignant transformation in hamster embryo cells.

Pharmacokinetic Studies

Studies showed that alkylamides from *Echinacea* species can readily be transported across Caco-2 monolayers indicating that they can be transported across the intestinal barrier and may contribute to the in-vivo effects of *Echinacea* preparations (Jager et al. 2002; Matthias et al. 2004) but not caffeic acid conjugates (Matthias et al. 2004).

Studies of nine healthy volunteers found that alkamides were rapidly absorbed and were measurable in plasma 20 minutes after *Echinacea* (*E. purpurea* and *E. angustifolia*) tablet ingestion after standard high-fat breakfast and remained detectable for up to 12 hours (Matthias et al. 2005a). The maximal concentrations for the sum of alkamides in human plasma were reached within 2.3 hours post ingestion and averaged 336 ng eq/ml plasma. No obvious differences were observed in the pharmacokinetics of individual or total alkamides. Caffeic acid conjugates could not be identified in any plasma sample at any time after tablet ingestion.

Alkamides dodeca-2*E*,4*E*,8*Z*,10*E/Z*-tetraenoic acid isobutylamides were found to be rapidly absorbed and measurable in plasma 10 minutes after administration of 0.21 and 0.9 mg *Echinacea purpurea* phytotherapeutic lozenges and remained detectable for 3 hours for the 0.21 mg lozenges and >3 hours for the 0.9 mg lozenges; 0.07 mg lozenges were measurable 20 minutes after administration and remained detectable for only 2 hours after the administration (Guiotto et al. 2008). A significant dose-independent downregulation of the proinflammatory cytokines IL-12p70, IL-8, IL-6, IL-10 and TNF was observed after 24 hours. The results demonstrated that pharmacokinetics of dodeca-2*E*,4*E*,8*Z*,10*E/Z*-tetraenoic isobutylamides were linear and that absorption was very rapid ($t_{1/2}$ =6 minutes) with apparently no lag time, thus indicating the possibility that a fraction of the drug was absorbed through the oral mucosa. In an earlier study, after oral ingestion, the arithmetic mean *C*(max) of dodeca-2*E*,4*E*,8*Z*,10*E/Z*-tetraenoic acid isobutylamides absorbed for *Echinacea purpurea* tincture was 0.40 ng/ml serum with 30 minutes *t*(max), while for the *Echinacea* tablet the *t*(max) of tablets was 45 minutes with a *C*(max) of 0.12 ng/ml (Woelkart et al. 2006). Both *E. purpurea* preparations led to the same effects on the immune system according to the concentration of proinflammatory cytokines TNF- α and IL-8. Twenty-three hours after oral application a significant downregulation of TNF- α and IL-8 in LPS pre-stimulated whole blood was found. However, no significant changes in the concentration of IL-6 were observed.

The alkylamide, undeca-2-ene-8,10-diynoic acid isobutylamide, a constituent of *E. purpurea* (Goel et al. 2011) and dodeca-2E,4E,8Z,10E/Z-tetraenoic acid isobutylamides (DTAI), the most abundant alkylamide in *E. purpurea*, were successfully quantified in the patients plasma after ingestion of *E. purpurea* extract by LC-MS/MS assay (Goey et al. 2012).

Traditional Medicinal Uses

Echinacea spp. are native to North America and were traditionally used by the Indian tribes for a variety of ailments, including mouth sores, colds and snakebites (Kindscher 1989). Traditional uses of *E. purpurea*, *E. angustifolia* and *E. pallida* include the following: respiratory infections, colds and flu, bronchitis, strep throat, toothache; urinary tract infections, herpes sores and gonorrhoea; skin disorders, staph infections, cold sores, ulcers, wounds, burns, insect bites, eczema, allergies and others; and rheumatoid arthritis (Hudson 2012).

Other Uses

Dried *Echinacea purpurea* (EP) can be used as a feed additive to improve the meat quality and oxidative status in Arbor Acres broilers (Lee et al. 2013). The addition of 0.5 and 1.0 % EP significantly increased water-holding capacity and decreased storage loss of breast and thigh fillets at 35 days old. Results for Trolox equivalent antioxidant capacity, catalase and superoxide dismutase were significantly higher for the 0.5, 1.0 and 2.0 % EP supplemental groups than control group in serum. Liver and spleen tissues results showed that the antioxidative enzyme activities were higher with EP powder at 35 days of age.

Studies showed *E. purpurea* to have potential as immunostimulatory feed additive against Newcastle disease virus in laying hens and in fattening pigs by intermittent application (Böhmer et al. 2009). The performance of laying hens was not impacted with feed additive application of pressed *E. purpurea* (aerial parts) juice in ethanol or fermented juice. Significant changes

were found in the number of lymphocytes, phagocytosis rate and Newcastle Disease Virus (NDV) antibody titre. The number of lymphocytes was highest in the group receiving ethanol juice for five consecutive days. Phagocytosis was reduced in both groups provided with ethanol juice (2 or 5 days). Highest NDV antibody titres were seen in the groups receiving fermented juice for 2 days. Additionally, phagocytosis of granulocytes was determined in fattening pigs (80–100 kg) after 5 days of *Echinacea* application with ethanol or fermented juice. A significant increase was found with both *Echinacea* formulations. The number of lymphocytes was also increased significantly in the groups provided with *Echinacea*.

Comments

Purple coneflower is easily propagated either from seeds or vegetatively by division, root cuttings and basal cuttings. It blooms throughout spring and summer and is pollinated by butterflies and bees.

Origin/Distribution

Sunflower is indigenous to the Americas—North America and Mexico. Lentz et al. (2008) presented archaeological, linguistic, ethnographic and ethnohistoric data indicating sunflower to be a pre-Columbian domesticate by ca. 2600 B.C. in Mexico. Sunflower cultivation was widespread in Mexico and extended as far south as El Salvador by the first millennium B.C., and was well known to the Aztecs, and is still in use by traditional Mesoamerican cultures today.

Studies on chloroplast variation by Wills and Burke (2006) confirmed a single origin of domesticated sunflower (*Helianthus annuus*). Evidence was provided that the extant domesticated sunflowers were the product of a single domestication event somewhere outside of Mexico. Evidence from multiple evolutionarily important loci and from neutral markers supported a single domestication event for extant cultivated sunflower in eastern North America (Blackman et al. 2011).

Agroecology

Sunflower prefers a mild temperature regime and is grown in many semiarid regions of the world at 0–3,000 m altitude. It is suited to most dryland

and irrigated farming systems but is not highly drought tolerant. It will grow in a wide range of temperatures 17–33 °C conditions with an optimum of 21–26 °C. It is quite frost hardy at the seedling stage, but subzero temperatures will injure and kill maturing plants. Sunflower grows best in full sun and is insensitive to day length. It is adaptable to a wide range of soils from sand to clay but thrives best in well-drained, moist and fertile soil with lots of organic matter. Sunflower is low in salt tolerance.

Edible Plant Parts and Uses

The seeds, flower petals and tender leaf petioles are edible (Hedrick 1972; Harrington 1974; Facciola 1990; Garland 1993; Barash 1997; Roberts 2000). Flower petals can be eaten raw or cooked but are best eaten in the young bud stage when it has an artichoke flavour. Young flower buds can be lightly boiled or steamed and eaten.

Sunflower ‘whole seed’ (fruit) are sold as a snack food after roasting within heated ovens with or without salt added and also used in confectionary. The roasted seeds or its roasted hulls can be used as a coffee and drinking chocolate substitute. Sunflower seeds can be ground into flour and processed into a peanut butter alternative, SunButter, especially in China, Russia, the United States, the Middle East and Europe. In Germany, it is used together with rye flour to make a sunflower whole seed bread called ‘Sonnenblumenkernbrot’. The germinated seed can be blended with water and left to ferment to make seed yoghurt. The sprouted seed can be eaten raw. The leaf petioles are boiled and mixed in with other foodstuffs.

Sunflower oil, extracted from the seeds, is used primarily as salad and cooking oil or in margarine for cooking. Sunflower oil is generally considered a premium oil because of its light colour, high level of unsaturated fatty acids and lack of linolenic acid, bland flavour and high smoke points.

Flour free from chlorogenic acid and high protein concentrate obtained from sunflower seeds could be added to wheat flour in as high a proportion

as 65 % in weight to prepare cookies containing 16 g/100 g high-quality protein, 80–90 % in relation to casein, and with adequate sensorial properties (Bourges et al. 1980).

Botany

Annual, erect, coarse herb, 100–300 cm, branched or unbranched with tap root. Stems green and fleshy, usually hispid. Leaves large, mostly cauline; alternate on petioles 2–20 cm long; lamina cordate to ovate, 10–40 by 5–40 cm, base subcordate or cordate, margins serrate, lower surface usually hispid, occasionally gland-dotted (Plate 1). Flowering heads 1–9 on peduncles 2–20 cm long. Involucres hemispheric or broader, 15–30 cm across (Plates 1, 2 and 3). Phyllaries 20–100+, ovate to lanceolate-ovate,

Plate 1 Flowers and leaves

Plate 2 Close-up of sunflowers

Plate 3 Sunflower with unusually large central disc

Plate 4 Sunflower seeds (achenes)

13–25×3–8 mm, margins usually ciliate, abaxial surfaces hirsute to hispid, rarely glabrate or glabrous, usually gland-dotted. Paleae 9–11 mm, 3-toothed (middle tooth long-acuminate). Ray florets sterile, yellow 13–100+; laminae 25–50 mm. Disk florets 150–1,000+; corollas 5–8 mm (throats swollen at bases), lobes usually reddish, sometimes yellow; anthers brownish to black, appendages yellow or dark, style branches yellow. Achene 3–15 mm, glabrate with pappi of 2 lanceolate scales plus 0–4 obtuse scales, dark gray with white stripes (Plates 4 and 5).

Nutritive/Medicinal Properties

Seed Nutrient/Phytochemicals

Quinic and isochlorogenic acids were identified in sunflower's seeds (Mourgue et al. 1975). Caffeic acid, the most predominant phenolic acid, along with *p*-hydroxybenzoic, *p*-coumaric, cinnamic, *m*-hydroxybenzoic, vanillic and syringic acids, was identified in both acid and base hydrolysates of sunflower seeds with only slight variations in concentrations among the cultivars (Leung et al. 1981). Relatively larger amounts of these acids were detected in the basic hydrolysates except in the cases of *p*-hydroxybenzoic, vanillic and syringic acids, indicating that these acids may exist in glycosidic form to a larger extent than in ester form in the cultivars examined. The principal phenolic constituents of sunflower seeds were chlorogenic acid (CGA),

smaller quantities of caffeic acid, cinnamic, coumaric, ferulic, sinapic and hydroxy-cinnamic and traces of vanillic, syringic and hydroxybenzoic acids were also present (Pedrosa et al. 2000). Total tocopherol in *H. annuus* seeds (32 accessions) was determined as 389.8 mg/kg seed comprising mainly 97.9 mg α -tocopherol, 1.8 mg β -tocopherol and 0.3 mg γ -tocopherol (Velasco et al. 2004).

Six different phenolic compounds were extracted from sunflower seeds and kernels (Žilić et al. 2010). Chlorogenic acid was the most abundant phenol. The chlorogenic acid content strongly correlated with total phenols ($R^2=0.93$). Other marked phenolics were caffeic acid, ferulic acid, rosmarinic acid, myricetin and rutin. The total tocopherols were significantly higher in kernels than in seeds of all sunflower hybrids. Concentrations in sunflower seeds ranged from

200.67 to 220.05 $\mu\text{g/g}$ and from 256.62 to 267.49 $\mu\text{g/g}$ in sunflower kernels where α -tocopherol was the dominant isomer in all samples. The α -tocopherol content was 98 % of averaged of the total tocopherols in all analyzed samples. β + γ -tocopherols were present in sunflower samples in amounts of 1.28–1.61 % of the total tocopherols. The level of δ -tocopherol was not significant in all sunflower samples and ranged from 0.42 to 0.52 % of the total tocopherols.

Seed reserve storage proteins of sunflowers were found to be globulins and albumins stored in protein bodies (Baudet and Mossé 1977; Buttrose and Lott 1978; Durante et al. 1989). The native globulin protein showed an apparent molecular weight of 300 K, but a 190 K band was present in some selfed sunflower lines (Durante et al. 1989). The globulin fraction amounted to 70–80 % of the total protein, light albumins constituted 20 % and 5–10 % for heavy albumins (Baudet and Mossé 1977). ‘Light’ albumins appeared as a rather homogeneous constituent with a low molecular weight of 11,000–1,600 (Raab and Schwenke 1975; Baudet and Mossé 1977) and an amino acid composition showing high amounts of methionine, cystine, arginine and glutamine (Baudet and Mossé 1977). ‘Heavy’ albumins possessed a molecular weight of 48,000 and a very different amino acid composition with a high level of lysine (Baudet and Mossé 1977). The major seed globulin called helianthinin was found to be an 11S protein with an oligomeric structure and 300 K MW (Schwenke et al. 1974, 1975) and to consist of 6 subunits (Plietz et al. 1978). Helianthinin was found to contain high contents of glutamic (26 %) and aspartic (14 %) acid and arginine (9.7 %) as well as a low content of sulphur-containing amino acids (Schwenke et al. 1979). 59 % of the acidic amino acids were present in an amidated form. The globulin contained 12 disulphide bridges per molecule. Low molecular weight (10,000–18,000) methionine-rich albumin was also found in sunflower seeds (Kortt and Caldwell 1990). The major albumins (4–8) contain high contents of glutamine/glutamic acid, asparagine/aspartic acid, arginine and cysteine, characteristic

of the 2S class of seed storage proteins. One exception was the small glutamine/glutamic acid content of albumin 6. Two of the sunflower albumins (7 and 8) with Mr 10,000 were methionine-rich proteins containing 16 residues percent methionine as well as 8 residues percent cysteine. The methionine-rich 2S sunflower seed protein was found to consist of a single polypeptide chain of 103 amino acids (molecular mass 12,133 Da) which contained 16 residues of methionine and 8 residues of cysteine (Kortt et al. 1991). The sunflower protein exhibited 34 % identity with the methionine-rich Brazil nut 2S protein. Helianthinin was found to be the most abundant storage protein of sunflower seeds; two populations of the monomeric form of helianthinin with denaturation temperatures of 65 and 90 °C were found (González-Pérez et al. 2004). The structural and interfacial properties of five different fractions of sunflower seed storage proteins, namely, lipid transfer protein (LTP), the methionine-rich 2S albumin SFA8 (sunflower albumin 8) and three mixtures of non-methionine-rich 2S albumins called Alb1 and Alb2 proteins (sunflower albumins 1 and 2), were characterized (Berecz et al. 2010). Heating affected all of the protein fractions, with SFA8 and LTP becoming more surface active than the native proteins after heating and cooling. LTP appeared to be less thermostable. SFA8 generated the greatest elastic modulus and formed the most stable emulsions, whereas LTP showed poorer emulsification properties. The mixed 2S albumin fractions showed moderate levels of surface activity but had the poorest emulsification properties among the proteins studied.

Peroxisome membrane proteins (PMPs) were found in sunflower seed cotyledons (Jiang et al. 1994). Six prominent nondenatured PMP complexes and ten prominent sodium dodecyl sulfate (SDS)-denatured polypeptides were identified in the membranes of the three types of peroxisomes: glyoxysomes, transition peroxisomes and leaf-type peroxisomes in the cotyledons.

The four most abundant anthocyanins in the hulls of purple sunflower seeds were identified as cyanidin3-glucoside, cyanidin3-malonylglucoside, cyanidin 3-xyloside and cyanidin 3-malonylxyloside (Mazza and Gao 1993). From the exudate of

germinating sunflower seeds was isolated a stereoisomer of diversifolide, 4,15-dinor-3-hydroxy-1(5)-xanthene-12,8-olide (designated sundiversifolide) with allelopathic activity (Ohno et al. 2001).

Analyses carried out in the United States reported that dried sunflower seed kernels have the following proximate composition (per 100 g edible portion): water 4.73 g, energy 584 kcal (2,445 kJ), protein 20.78 g, total lipid 51.46 g, ash 3.02 g, carbohydrates 20.00 g, total dietary fibre 8.6 g, total sugars 2.62 g, Ca 78 mg, Fe 5.25 mg, Mg 325 mg, P 660 mg, K 645 mg, Na 9 mg, Zn 3.14 mg, Cu 0.824 mg, Mn 1.626 mg, Se 8.2 µg, vitamin C 1.4 mg, thiamine 0.555 mg, riboflavin 0.333 mg, niacin 2.832 mg, pantothenic acid 0.976 mg, vitamin B-6 0.366 mg, total folate 423 µg, choline 95.8 mg, vitamin A 53 IU, vitamin E (α-tocopherol) 0.05 mg, vitamin K (phylloquinone) 9 µg, β-carotene 32 µg, total saturated fatty acids 0.254 g, total monounsaturated fatty acids 0.303 g, total polyunsaturated fatty acids 0.627 g, phytosterols 124 mg, tryptophan 0.247 g, threonine 0.928 g, isoleucine 1.053 g, leucine 1.964 g, lysine 1.671 g, methionine 0.213 g, cystine 0.334 g, phenylalanine 1.103 g, tyrosine 0.827 g, valine 1.161 g, arginine 2.411 g, histidine 0.664 g, alanine 1.070 g, aspartic acid 2.916 g, glutamic acid 4.437 g, glycine 1.095 g, proline 1.099 g and serine 1.195 g (USDA 2012).

Sunflower oil is the non-volatile oil expressed from the seeds. British Pharmacopoeia Commission (2005) listed the following profile: palmitic acid (4–9 %), stearic acid (1–7 %), oleic acid (14–40 %) and linoleic acid (48–74 %). Sunflower oil also contains lecithin, tocopherols, carotenoids and waxes and has a high vitamin E content. It is a combination of monounsaturated and polyunsaturated fats with low saturated fat levels.

The seed lipids from five sunflower mutants, two with high-palmitic acid contents, one of them in high-oleic background and three with high-stearic acid contents, were found to have increased saturated fatty acid content with high levels of triacylglycerols (Alvarez-Ortega et al. 1997). No difference between mutants and standard sunflower lines (controls) was found in minor fatty acids: linolenic, arachidic and

behenic. In the high-palmitic mutants, palmitoleic acid (16:1n–7) and some palmitolinoleic acid (16:2n–7, 16:2n–4) were present. Phosphatidylinositol, the lipid with the highest palmitic acid content in controls, also had the highest content of palmitic or stearic acids, depending on the mutant type. The triacylglycerol (TAG) composition of oils from new high-saturated sunflower lines was found to be characterized by triacylglycerol species with asclepic (*cis*, Δ 11-octadecenoic acid, isomer of oleic acid), araquidic or behenic acids (Fernández-Moya et al. 2000). The TAG molecular species that contained asclepic acid instead of oleic acid were found to have a longer retention time.

High-palmitoleic-acid sunflower mutant was found to have contents of unusual acyl chains up to 20 % (12 % of 16:1 Δ 9, 5 % of 16:2 Δ 9,12 and 6 % of 18:1 Δ 11), whereas these fatty acids were found in negligible amounts in common sunflower cultivars (Salas et al. 2004). The high-palmitoleic-acid phenotype was associated with a concerted reduction in the fatty acid synthase II activity with respect to the control lines and an increase of stearoyl-ACP desaturase activity with respect to the high-palmitate mutant line. The high-palmitic, low-palmitoleic sunflower mutant lines CAS-18 and CAS-25 (with a high-oleic background) had been selected from the high-stearic mutant CAS-3 (Serrano-Vega et al. 2005). In these high-palmitic lines, desaturation of palmitic acid and the synthesis of palmitoleic acid and its derivatives (asclepic and palmitolinoleic acids) were reduced, and stearic content increased. Introducing a FA thioesterase from a high-palmitic line (e.g., CAS-5) into the high-stearic CAS-3 increased the stearic acid content from 27 to 32 % in the new high-stearic line CAS-31. Seed oils from new recombinant high-stearic sunflower lines CAS-29 and CAS-30 were found to contain up to 34.5 % of stearic acid, whereas CAS-15 and CAS-33 with a high-oleic-acid background contained only 24.9 and 17.4 % of stearic acid, respectively (Fernández-Moya et al. 2005).

As seen from above, there are various types of sunflower oils produced which differs in the

levels and composition of fatty acid profiles. The USDA (2012) has analyzed the nutrient composition (per 100 g values) of various types of vegetable sunflower oils in the United States:

- (a) High-oleic (70 % and over) vegetable sunflower oil: energy 884 kcal (3,699 kJ); vitamin E (α -tocopherol) 41.08 mg; vitamin K (phylloquinone) 5.5 μ g; total fat 100 g; total saturated fatty acids 9.748 g, 15:0 (pentadecanoic) 0.800 g, 16:0 (palmitic) 3.62 g, 18:0 (stearic) 4.32 g, 22:0 (behenic) 1.00 g; total monounsaturated fatty acids 83.594 g, 18:1 undifferentiated (oleic) 82.63 g, 20:1 (gadoleic) 0.964 g; total polyunsaturated fatty acids 3.798 g, 18:2 undifferentiated (linoleic) 3.606 g, 18:3 undifferentiated (linolenic) 0.192 g
- (b) Mid-oleic, vegetable sunflower oil, industrial, principal frying and salad oils: energy 884 kcal (3,699 kJ); vitamin E (α -tocopherol) 41.08 mg; vitamin K (phylloquinone) 5.4 μ g; Fe 0.03 mg; choline 0.2 mg; total fat 100 g; total saturated fatty acids 9.009 g, 14:0 (myristic) 0.057 g, 16:0 (palmitic) 4.219 g, 17:0 (margaric) 0.037 g, 18:0 (stearic) 3.564 g, 20:0 (arachidic) 0.297 g, 22:0 (behenic) 0.836 g; total monounsaturated fatty acids 57.334 g, 16:1 undifferentiated (palmitoleic) 0.095 g, 16:1 c 0.095 g, 18:1 undifferentiated (oleic) 57.029 g, 18:1 c 57.029 g, 20:1 (gadoleic) 0.0211 g; total polyunsaturated fatty acids 28.962 g, 18:2 undifferentiated (linoleic) 28.924 g, 18:2 n-6 c.c 28.705 g, 18:2i 0.219 g, 18:3 undifferentiated (linolenic) 0.037 g, 18:3 n-3 c.c.c (α linoleic) 0.037 g; total *trans*-fatty acids 0.219 g
- (c) Linoleic (approx. 65 %) vegetable sunflower oil: energy 884 kcal (3,699 kJ); vitamin E (α -tocopherol) 41.08 mg; vitamin K (phylloquinone) 5.4 μ g; choline 0.2 mg; total fat 100 g; total saturated fatty acids 10.300 g, 16:0 (palmitic) 5.900 g, 18:0 (stearic) 4.500 g; total monounsaturated fatty acids 19.500 g, 18:1 undifferentiated (oleic) 19.500 g; total polyunsaturated fatty acids 65.700 g, 18:2 undifferentiated (linoleic) 65.700 g; phytosterols 100 mg

- (d) Linoleic (less than 60 %) vegetable sunflower oil: energy 884 kcal (3,699 kJ); vitamin E (α -tocopherol) 41.08 mg; vitamin K (phylloquinone) 5.4 μ g; Fe 0.03 mg; total fat 100 g; total saturated fatty acids 10.100 g, 16:0 (palmitic) 5.400 g, 18:0 (stearic) 3.500 g; total monounsaturated fatty acids 45.400 g, 16:1 undifferentiated (palmitoleic) 0.200 g, 18:1 undifferentiated (oleic) 45.300 g; total polyunsaturated fatty acids 40.100 g, 18:2 undifferentiated (linoleic) 39.800 g, 18:3 undifferentiated (linolenic) 0.200 g; phytosterols 100 mg
- (e) Linoleic (hydrogenated) vegetable sunflower oil: energy 884 kcal (3,699 kJ); vitamin E (α -tocopherol) 41.08 mg; β -tocopherol 1.69 mg; γ -tocopherol 9.09 mg; δ -tocopherol 2.04 mg; vitamin K (phylloquinone) 5.4 μ g; total fat 100 g; total saturated fatty acids 13.00 g, 16:0 (palmitic) 7.100 g, 18:0 (stearic) 5.500 g; total monounsaturated fatty acids 46.200 g, 18:1 undifferentiated (oleic) 46.200 g; total polyunsaturated fatty acids 40.100 g, 18:2 undifferentiated (linoleic) 35.300 g, 18:3 undifferentiated (linolenic) 0.900 g; phytosterols 10 mg

As a frying oil, sunflower oil behaves as a typical vegetable triglyceride. In cosmetics, it has smoothing properties and is considered noncomedogenic. Only the high-oleic variety possesses shelf life suitable for commercial cosmetic formulation.

Flower Phytochemicals

Total carotenoids in *H. annuus* cv. Sunrich orange flower was 1023.8 μ g/g FW, in cv. Sonia (orange flowers) 1599.6 μ g/g FW, in cv. Sunrich lemon (yellow flowers) 305.2 μ g/g FW, and in cv. Valentine (yellow flowers) 143.8 μ g/g FW (Kishimoto et al. 2007).

Sixty-nine compounds were identified in the essential oils of leaves and flowers of sunflower plants. Significant percentage variations were recorded between the leaves and flowers oil content. The monoterpenes were the major compounds present in both essential oils examined.

α -Pinene content was higher in flowers (72.6 %) than in leaves (28.6 %). The content of sabinene was about two times higher in leaves than in flowers.

Lipids in sunflower pollens rich in omega-3 linolenic acid including triglycerides, free fatty acids, phosphatidylethanolamines, phosphatidic acids and phosphatidylcholines were highly phagostimulatory (Lin and Mullin 1999). Other important phagostimulatory components included a hydroxycinnamic acid-polyamine amide, N(1),N(5),N(10)-tri[(*E*)-*p*-coumaroyl] spermidine and a flavonol, quercetin β -3-*O*-glucoside. The major component of sunflower pollen lipids was the seco-triterpene helianyl octanoate, followed by new β -diketones as second major group of compounds that included -phenyl- β -diketones (Schulz et al. 2000). Further lipid classes present were related hydroxyketones and diols and also present were β -dioxoalkanoic acids which most likely were biogenetic precursors of the diketones. Also, the composition of the pollen coat resembled the total extract, but lacked dioxoalkanoic acids and certain estolides. Sunflower pollen coat was found to be richer in lipids (8 %) than stigma (2.2 %) on fresh weight basis (Shakya and Bhatla 2010). Neutral lipids were preferentially found localized in the pollen coat. Neutral esters and triacylglycerols (TAGs) were the major lipidic constituents in pollen grains and stigma, respectively. Lignoceric acid (24:0) and *cis*-11-eicosenoic acid (20:1) were specifically expressed only in the pollen coat. Lipase activity was expressed both in pollen grains and stigma, while stigma exhibited a better expression of acyl-ester hydrolase activity than that of observed in both the pollen fractions. Expressions of two acyl-ester hydrolases (41 and 38 kDa) were found to be specific to pollen coat.

The saponified sunflower ligule extract afforded two esters of *ent*-kaur-16-en-19-oic and *ent*-trachyloban-19-oic acids with thujanol (Pyrek 1984). The following diterpenoids were also identified: *ent*-kaur-16-en-19-al; *ent*-trachyloban-19-al; *ent*-kauran-16 β -ol; *ent*-kauran-16 α -ol; *ent*-kauran-16 β , 19-diol; *ent*-atisan-16 α -ol; and *ent*-atisan-16 β -ol. Loliolide acetate was also

isolated from an acetylated portion of the same extract. Three bisdesmosidic triterpenoid saponins, helianthoside 1 (1), 2 (2) and 3 (3), and monodesmoside 4 were isolated from sunflower flowers (Bader et al. 1991). Germacranolides 3-*O*-methylniveusin A and 1,10-*O*-dimethyl-3-dehydroargophyllin B diol, the eudesmanoic acid eudesma-1,3,11(13)-trien-12-oic acid and the diterpene 7-oxo-trachyloban-15 α , 19-diol and 5-hydroxy-4,6,4'-trimethoxyaurone were isolated from the flower epicuticle of sunflower (Alfatafta and Mullin 1992). Two antifungal benzopyran derivatives, 6-acetyl-2,2-dimethyl-1,2-benzopyran (1) and 6-acetyl-7-hydroxy-2,2-dimethyl-1,2-benzopyran (2), were isolated from the ethanol extract of sunflower receptacles (Satoh et al. 1996).

Floral chemicals with insect feeding-deterrent activity included the following: sesquiterpene lactones (e.g., argophyllin A, 3-*O*-methylniveusin A and germacranolide angelates), diterpenes (grandifloric acid and its 15-angelate) and phenolics, flavonoids (nevadensin and quercetin β -7-*O*-glucoside) and dicaffeoylquinic acids (Mullin et al. 1991) and sesquiterpenes, germacranolides 3-*O*-methylniveusin A and 1,10-*O*-dimethyl-3-dehydroargophyllin B diol, the eudesmanoic acid eudesma-1,3,11(13)-trien-12-oic acid, the diterpene 7-oxo-trachyloban-15 α , 19-diol and hydroxy-4,6,4'-trimethoxyaurone (Alfatafta and Mullins 1992).

Eleven diterpene compounds were obtained from the flower disc of *H. annuus* and identified as *ent*-kaurane-2 α , 16 α -diol (1) and *ent*-kaurane-15 α ,16 α -epoxy-17-al-19-oic acid (2) and nine known diterpenes, *ent*-kaurane-16P-ol (3), phyllocladan-16 β -ol (4), *ent*-atisan-16 α -ol (5), grandifloric acid (6), angeloylgrandifloric acid (7), *ent*-kaurane-16-en-19-oic acid (8), *ent*-kaurane-17-hydroxy-15-en-19-oic acid (9), *ent*-kaurane-16 β , 17-dihydroxy-19-oic acid (10) and ciliaric acid (11) (Suo et al. 2007). Two new oleanane-type triterpene glycosides, named helianthosides 4 (4) and 5 (5), along with four known triterpene glycosides, helianthosides 1 (1), 2 (2), 3 (3) and B (6), were isolated from an n-butanol-soluble fraction of a methanol extract

of sunflower (*Helianthus annuus*) petals (Ukiya et al. 2007).

Eight fatty acid esters of triterpene alcohols (1–8), four free triterpene alcohols (9, 12, 17 and 18), four diterpene acids (19–22), two tocopherol-related compounds (23 and 24), four estolides (25–28), three syn-alkane-4,6-diols (29–31), one 1,3-dioxoalkanoic acid (32) and one aliphatic ketone (33), along with the mixture of free fatty acids, were isolated from the diethyl ether extract of the pollen grains of sunflower (Ukiya et al. 2003b). Sunpollenol and five other rearranged 3,4-seco-tirucallane-type triterpenoids (1–6) were isolated from the diethyl ether extract of the pollen grains of sunflower (Ukiya et al. 2003a). Two new diterpenes, 2 β , 16 β -*ent*-kaurane diol and 15 α , 16 α -epoxy-17 β -*al-ent*-kaurane-19-oic acid, were isolated from *Helianthus annuus* (Suo et al. 2006).

Barker (1997) and Foster et al. (2003) found that nonpolar (pentane) and moderately polar (dichloromethane) extracts of sunflower bracts contained compounds that stimulated oviposition by females banded sunflower moth (BSFM) *Cochylis hospes*. Two diterpenoid alcohols *ent*-kauran-16 α -ol and *ent*-atisan-16 α -ol were isolated from a dichloromethane extract of pre-bloom sunflowers heads and found to stimulate female BSFM. Two diterpenoid alcohols, *ent*-kauran-16 α -ol (1) and *ent*-atisan-16 α -ol (2), along with *ent*-trachyloban-19-oic acid (3) and *ent*-kaur-16-en-19-oic acid (4), were isolated from pre-bloom sunflower heads as oviposition stimulants for the female BSFM (Morris et al. 2005). Compounds 3 and 4 failed to stimulate significant egg laying at any of the dosages tested. Three diterpenoids, grandifloric acid (1), 15 β -hydroxy-*ent*-trachyloban-19-oic acid (2) and 17-hydroxy-16 α -*ent*-kauran-19-oic acid (3), were isolated from polar fractions of pre-bloom sunflower head extract and found to stimulate oviposition by female BSFM (Morris et al. 2009).

Sesquiterpenes and sesquiterpene lactones such as germacrolides and heliangolides were found as major natural compounds in linear and capitate glandular trichomes of sunflower, *Helianthus annuus* (Göpfert et al. 2005, 2009, 2010).

The key enzymes of sesquiterpene lactone biosynthesis in the glandular trichomes of sunflower anthers were identified as two germacrene A synthases HaGAS1 and HaGAS2 (Göpfert et al. 2009) which also occurred in the roots. In addition using reverse transcription-PCR experiments, a third germacrene A synthase, HaGAS3, was identified (Göpfert et al. 2010). The new enzyme occurred in plant tissues not linked to the presence of specific trichomes (e.g., cotyledons) and was absent in roots. The experiments showed that independently regulated pathways for the first cyclic sesquiterpene, germacrene A, were present in sunflower.

Sixty-nine compounds were identified in the essential oils of leaves and flowers of sunflower cultivars Carlos and Florom 350 plants grown in Tuscany, Italy (Ceccarini et al. 2004). The monoterpenes were the major compounds present in both essential oils examined. α -Pinene content was higher in flowers (72.6 %) than in leaves (28.6 %). The content of sabinene was about 2 times higher in leaves than in flowers. There were no significant differences between the essential oil compositions of the oils obtained from the same organs of the two cultivars. Pinene, *cis*-verbenol and β -gurjunene were in both the main volatiles but with significant quantitative differences; moreover, Florom oil was characterized by a greater variety of constituents (Cioni et al. 2005). The fixed oil and the waxes composition showed a general qualitative homogeneity, for both cultivars, even though marked quantitative differences were observable.

Sunflower flower was found to contain ubiquitin, a 76-amino acid protein, the most conserved polypeptide (Binet et al. 1989). Accumulation of polyubiquitin genes (UbB1 and UbB2) were found to be mainly induced by heat stress or during flower development (Binet et al. 1991a, b). Accumulation levels of the 0.7- and 1.6-kb mRNAs (monoubiquitin and hexaubiquitin, respectively) actually decreased during late embryogenesis. In contrast, tetraubiquitin (1.3 kb) mRNAs were approximately eight- to tenfold more abundant in mature seeds than in young embryos (Almoguera et al. 1995).

Leaf Phytochemicals

Sunflower leaf tissues contained allagochrome and chlorogenic acid (Habermann 1967). Sesquiterpene lactones niveusin C (I) and 15-hydroxy-3-dehydrodesoxyfruticin (II) were found in the young leaves (Spring and Hager 1982; Spring et al. 1982b, 1986). In leaves grown in high-intensity light (100 W/m²), the concentration of sesquiterpene lactone (SQL) I increased sixfold and of SQL II 19-fold compared to leaves in low-intensity light (5 W/m²) (Spring et al. 1986). Sesquiterpene lactones niveusin C, argophyllin B, 15-hydroxy-3-dehydrodesoxyfruticin and three germacranolides of the niveusin A-type were identified in the resinous content of multicellular capitate glandular trichomes of sunflower leaves (Spring et al. 1987, 1989). Seven sesquiterpene lactones 4,5-dihydroniveusin A, argophyllin B, argophyllin A, 15-hydroxy-3-dehydrodesoxyfruticin, niveusin B, 1,2-anhydridoniveusin A and an unidentified epoxide were isolated from sunflower leaves (Chou and Mullin 1993).

The medium polar fractions from sunflower leaf aqueous extracts afforded five guaianolides, the annuolides A–E (Macías et al. 1993b). From the medium polar active fractions, a sesquiterpene heliannoul A was isolated (Macías et al. 1993b). From the moderately polar fractions of sunflower leaf aqueous extract, 3 sesquiterpenes heliannuols B–D were isolated (Macías et al. 1994).

From an aqueous sunflower leaf extract, six new heliannuols were isolated: three 7,10-heliannanes, heliannuols F (1), I (4) and J (5), and three 7,11-heliannanes, heliannuols G (2), H (3) and K (6) (Macías et al. 1999c). Allelopathic sesquiterpene lactones found in the leaves included the following: 1,2-anhydrido-4,5-dihydroniveusin A, annuithrin, annuolides A,C,F,G, 8 β -angeloyloxycumambranolid, helivypolides A–B, melampolides, heliangolides, *cis,cis*-germacranolides and *trans,trans* germacranolides (Macías et al. 1996a). Eleven allelopathic compounds (trivial and systematic names) were isolated from the leaves: heliannoul A (7*R*,11-heliannane-5,10*S*-diol), heliannoul B (7*R*,10*R*-heliann-8(9)-ene-5,11-diol), heliannoul C (8*S**,11-heliann-7(14)-ene-5,10*R**-diol), heliannoul D (7*R*,10*R*-helianane-5,11-diol), helian-

nuol E (8*R*,10*R*-heliann-7(14)-ene-5,11-diol), heliannoul F (5,11-dihydroxy-7*S*,10*R*-heliannan-8-one), heliannoul G (7*S*,11-heliann-9(10)-ene-5,8*R*-diol), heliannoul H (7*S*,11-heliann-9(10)-ene-5,8*S*-diol), heliannoul I (7*R*,8*S*-epoxy-7,10*R*-heliannane-5,11-diol), heliannoul J (7*S*,8*R*-epoxy-7,10*R*-heliannane-5,11-diol) and heliannoul K (5-hydroxy-7*R*,11-heliannan-10-one) (Macías et al. 2000). Five allelochemicals, chlorogenic, caffeic, syringic, vanillic and ferulic acids, were identified in the leaves (Ghaffar et al. 2001). It has been found that total phenols in the leaves were more (0.0316 mM/g) as compared to the stem (0.016 mM/g).

Sesquiterpene lactones annuolide E and leptocarpin, and the sesquiterpenes heliannuols A, C, D, F, G, H, I and L, helibisabonol A and helibisabonol B and bisnorsesquiterpene, annuionone E, were isolated from CH₂Cl₂ leaf extract (Macías et al. 2002b). (±)-Helibisabonol A, a new sesquiterpene with phytotoxic activity, was isolated from sunflower leaves (Macías et al. 2002a). The polar bioactive fractions of the aqueous sunflower leaf extract yielded 10 lignans and a phenylpropanoid: pinoresinol (1), siringaresinol (2), medioresinol (3), buddlenol E (4), lariciresinol (5), 7-hydroxylariciresinol (6), neo-olivil (8), dihydro-dehydrodiconiferilic alcohol (9), 1-(4'-hydroxy-3'-methoxyphenyl)-2-[4''-(3-hydroxypropyl)-2''-methoxyphenoxy]propane-1,3-diol (10) and 3-(4-hydroxy-3,5-dimethoxyphenyl)propan-1-ol (11) (Macías et al. 2004b). Compound 7 tanegool was isolated as a natural aglycone. The polar bioactive fractions of *Helianthus annuus* cv. Stella and SH-222 yielded eight apocarotenoids, annuionones A to H (Macías et al. 2004a). From the medium polar active fraction of leaf aqueous extract, allelopathic spiroterpenes heliespiroenes C–E were isolated (Macías and Galindo 2005).

Annuionone H was isolated from sunflower aqueous leaf extract (Anjum and Bajwa 2005). Six sesquiterpene lactones (annuolide H, helivypolides F, H, I and J, and helieudesmanolide A), 1,2-anhydroniveusin A, 1-methoxy-4,5-dihydroniveusin and 15-hydroxy-3-dehydrodesoxyfruticin were isolated from sunflower leaves (Macías et al. 2006a). From the medium, polar bioactive fractions of sunflower leaf aqueous

extract heliespiranes with a novel spiro heterocyclic sesquiterpene skeleton, namely, heliespirones B and C, were isolated (Macías et al. 2006b).

Stem/Root Phytochemicals

Sunflower stems yielded small quantity of trachyloban-19-oic and (–)-kaur-16-en-19-oic acids trachyloban-19-oic and (–)-kaur-16-en-19-oic acids with antimicrobial property (Mitscher et al. 1983). The following main volatile components were found in the headspace profile of sunflower stems: α -pinene (86.2 %), β -pinene (4.1 %), butyl acetate (2.3 %) camphene (1.9 %) (Buchbauer et al. 1993). Other important components (<1 %) included the following: acetic acid, α -thujone, limonene, β -phellandrene, (*E*)-2-hexen-1-ol, 3-heptanol, decanal, octanol, benzaldehyde, noanol, 2-nonanol, linalool, bornyl acetate, geranyl acetate, β -caryophyllene and vanillin. Minor headspace constituents of sunflower stems included anisole, butanol, ethyl acetate, fenchone, hexanal, *Z*-3-hexenol, hexyl acetate, pentanol, propyl acetate, α -terpineol, β -thujone and 2-undecanol. Three alleochemicals were found in the stem (chlorogenic, ferulic and vanillic acids) and only one (ferulic acid) in the roots (Ghafar et al. 2001).

Aerial Parts/Plant/Seedling Phytochemicals

A sesquiterpene lactone, annuithrin, a germacranolide with an α -methylene- γ -lactone moiety, was isolated from sunflower (Spring et al. 1981). From the ethanol sunflower extract, a new germacranolide with an α -methylene- γ -lactone moiety, the heliangolide niveusin B and its ethoxy derivative, was isolated (Spring et al. 1982a). A furanoheliangolide derivative, 4,5-dihydroniveusin A, as well as niveusin B, argophyllin A and B, diterpene acid, grandifloric acid, ciliaric acid and 17-hydroxy-*ent*-isokaur-15(16)-en-19-oic acid were isolated from a Texas population of *Helianthus annuus* (Melek et al. 1985). The sesquiterpene (–)-heliespinore A, a potential

allelopathic agent, was isolated from sunflower var. SH-222 (Macías et al. 1998a). Two alleochemicals, namely, sesquiterpene lactones, helivypolide D and helivypolide E and the bisnorsesquiterpene, annuionone D, were isolated from sunflower (Macías et al. 1999a). The polar bioactive fractions of *Helianthus annuus* cv. Stella and SH-222 yielded eight apocarotenoids, annuionones A to H (Macías et al. 2004a). Structures for annuionone A, B and E were revised. Five flavonoids, namely, the flavonol tambulin, the chalcones kukulcanin B and heliannone A and the flavanones heliannones B and C, were isolated from sunflower cultivar VYP (Macías et al. 1997). Three ionone-type bisnorsesquiterpenes annuionones A–C and the norbisabolene, helinorbisabone, were isolated from sunflower (Macías et al. 1998b). Two bioactive flavonoids heliannone A (1) and (R,S)-heliannone B (2) were identified from *Helianthus annuus* cultivars (Rao et al. 2001). The following alleochemicals were reported from sunflowers: (\pm)-heliannuol D (Vyvyan and Looper 2000), heliannuol C (Biswas et al. 2006), heliannuols A and K (Ghosh et al. 2007), heliannuol A and D (Tuhina et al. 2002) and natural enantiomers of (–)-heliespirone A and (+)-heliespirone C (Miyawaki et al. 2012). An *ent*-kaurane glucoside named helikauranoside A was isolated together with three known *ent*-kaurane-type diterpenoids: (–)-kaur-16-en-19-oic acid, grandifloric acid and paniculoside IV from sunflower aerial parts (Macías et al. 2008).

Three polyacetylenes, 8-(β -D-glucopyranosyloxy)-3-hydroxy-1,9,14-pentadecatriene-4,6-diyne, termed ‘helian’ (1), 8-acetoxy-3-hydroxy-1,9,14-pentadecatriene-4,6-diyne (2), and 3,8-dihydroxy-1,9,14-pentadecatriene-4,6-diyne (3), were isolated from sunflower seedlings (Hong et al. 2009). Compounds 1 and 2, having a β -glucose and an acetoxy group at C-8, respectively, showed a weak effect on the growth of roots and shoots of rice (*Oryza sativa*) and cress (*Lepidium sativum*), while compound 3, having a free hydroxyl group at C-8, exhibited a growth promoting effect on the roots and shoots of rice and cress.

Some of the reported pharmacological properties of sunflowers are discussed below.

Antioxidant Activity

Of the three antioxidant assays used, the aqueous extract of striped sunflower seed cotyledon at 30 µg/ml showed a higher antioxidant capacity value (FRAP, 45.27 µmol; DPPH, 50.18 %; ORAC, 1.5 Trolox equivalents) than the ethanol extract (FRAP, 32.17 µmol; DPPH, 15.21 %; ORAC, 0.50 Trolox equivalents) (Giada and Mancini-Filho 2009). When compared with the synthetic antioxidant butylated hydroxytoluene, the antioxidant capacity of the aqueous extract varied from 45 to 66 %, according to the used assay. Different concentrations (50–250 ppm) of α -tocopherol and myricetin exhibited synergistic antioxidant effect during autoxidation of triacylglycerols of sunflower oil (TGSO) at 100 °C (Marinova et al. 2008). The best synergistic effect was achieved with an equal molar ratio of α -tocopherol and myricetin and at total concentration of the mixtures lower than 10×10^{-4} M. Myricetin was found to be a more effective and stronger antioxidant than α -tocopherol. Studies found that sunflower oil with high content of oleic and palmitic acid (HOHPSO) and containing γ -tocopherol as the most abundant natural antioxidant had a very high stability at frying temperatures and that mixtures of HOHPSO- α and HOHPSO- γ would be an excellent alternative to fulfill the frying performance required by the processors and the vitamin E content claimed by the consumers (Marmesat et al. 2008).

Antiinflammatory Activity

Oleanane-type triterpene glycosides, helianthosides 1–6, isolated from the petals exhibited marked inhibitory activity against 12-*O*-tetradecanoylphorbol-13-acetate (TPA)-induced inflammation (1.7 nmol/ear) in mice with ID₅₀ values in the range 65–262 nmol/ear (Ukiya et al. 2007). Three diterpene acids, grandiflorolic, kaurenoic and trachylobanoic acids,

isolated from the petroleum ether extract of sunflower exhibited antiinflammatory activity on the generation of inflammatory mediators in lipopolysaccharide (LPS)-activated RAW 264.7 macrophages (Díaz-Viciedo et al. 2008). At non-toxic concentrations, these compounds reduced, in a concentration-dependent manner, nitric oxide (NO), prostaglandin E(2) (PGE(2)) and tumour necrosis factor (TNF- α) production, as well as expression of inducible nitric oxide synthase (NOS-2) and cyclooxygenase-2 (COX-2). All diterpenoids displayed significant in-vivo antiinflammatory activity and suppressed the 12-*O*-tetradecanoylphorbol-13-acetate (TPA)-mouse ear edema. Also, inhibition of myeloperoxidase (MPO) activity, an index of cellular infiltration, was observed. Results of studies suggested that oral administration of aqueous sunflower seed extract to ovalbumin-induced asthmatic mice exhibited considerable potential in reducing the asthma-like symptoms (Heo et al. 2008). The extract induced a decrease in CD4+ cell number, interleukins IL-4/IL-13 expression and IgE secretion levels in the lungs.

Immunomodulatory Activity

Triterpenoid saponins from several plants including sunflower exhibited mitogenic effects on murine spleen and thymus cells, as well as on human mononuclear cells in-vitro (Plohmann et al. 1997). The activity of murine bone marrow macrophages was stimulated in a chemiluminescence assay, and an induction of cytotoxic macrophages and a TNF- α release from murine macrophages were observed. Water and hydro-ethanol extracts of sunflower plant residues were found to modulate the immune functions of isolated ovine neutrophils when tested for adhesion and superoxide production induced with PMA (Farinacci et al. 2008).

Antiviral Activity

Among the 24 terpenoids and lipids (1–4, 6–9, 12 and 19–33) and 6 free triterpene triols (10, 11 and 13–16),

derived from their fatty acid esters (2, 3 and 5–8) by alkaline hydrolysis of sunflower pollens, 21 compounds possessing a di- or a polycyclic ring system in the molecule (1–4, 6–16 and 19–24) showed potent inhibitory effects on Epstein–Barr virus early antigen (EBV-EA) induction (91–100 % inhibition at 1×10^3 mol ratio/TPA) by the tumour promoter, 12-*O*-tetradecanoylphorbol-13-acetate (TPA), in Raji cells (Ukiya et al. 2003b). Six new rearranged 3,4-seco-tirucallane-type triterpenoids (1–6) isolated from the diethyl ether extract of the pollen grains of sunflower exerted potent inhibitory effects on the induction of Epstein–Barr virus early antigen (EBV-EA) induced by the tumour promoter 12-*O*-tetradecanoylphorbol 13-acetate (TPA) in Raji cells (97–100 % inhibition at 1×10^3 mol ratio/TPA) (Ukiya et al. 2003a).

Antimicrobial Activity

Annuithrin, a germacranolide from sunflower, exhibited antibacterial activity (Spring et al. 1981). Sesquiterpene lactones niveusin C (I) and 15-hydroxy-3-dehydrodesoxyfruticin (II), isolated from sunflower leaves, exerted an antibiotic effect on Gram-negative and Gram-positive bacteria as well as on some fungi (Spring et al. 1982b). The minimal inhibitory concentration (MIC) of compound II (15-hydroxy-3-dehydrodesoxyfruticin), for example, was 15 µg/ml for *Bacillus brevis* and 95 µg/ml for the fungus *Eremothecium ashbyi*. Heliangolides from sunflower, niveusin B and its ethoxy derivative exhibited antimicrobial activity (Spring et al. 1982a). Sesquiterpene lactones from noncapitate sunflower trichomes were found to possess antimicrobial activity (Spring et al. 1992). Two benzopyran derivatives, 6-acetyl-2,2-dimethyl-1,2-benzopyran (1) and 6-acetyl-7-hydroxy-2,2-dimethyl-1,2-benzopyran (2), from the ethanol extract of sunflower receptacles exhibited antifungal activity against *Pyricularia oryzae* as the test fungus (Sato et al. 1996). A lipid transfer protein isolated from germinating sunflower seeds (Ha-AP10) displayed strong antimicrobial activity against a model fungus and a weak

inhibitory effect on the growth of *Alternaria alternata*, a fungus known to naturally attack sunflower seeds (Gonorazky et al. 2005).

Anticancer Activity

Annuithrin, a germacranolide from sunflower, inhibited DNA/RNA synthesis in cells of the ascitic form of Ehrlich carcinoma (Spring et al. 1981). Sesquiterpene lactones niveusin C (I) and 15-hydroxy-3-dehydrodesoxyfruticin (II), isolated from sunflower leaves, exhibited cytotoxic effects on mouse myeloma cells (NS-1) (Spring et al. 1982b). Compound II causes a 50 % inhibition of cell proliferation (ED_{50}) at a concentration of 170 nM, compound I (niveusin C) at 220 nM. The LD_{50} values were 0.15 µg/ml for II and 1.24 µg/ml for I, respectively. By measuring ^{14}C -labelled thymidine, uridine and leucine incorporation into murine cells of the ascitic form of Ehrlich carcinoma (EAC), it was shown that compounds I and II inhibited DNA and RNA synthesis but did not affect the translation processes involved in protein synthesis. Furthermore, it could be shown that the exocyclic methylene group in the molecules of I and II played an important role in triggering the described inhibitory effects. Saponins from *H. annuus* exhibited cytotoxic activities in the murine T-cell lymphoma YAC-1 and in the β -galactosidase-transfected murine mastocytoma P815-tumour cell models (Bader et al. 1996). Recently, some of the diterpenes compounds isolated from the sunflower head showed cytotoxic activities on cancer cell lines—SF-268, MCF-7 and HepG2 cell lines (Suo et al. 2007).

Antidiabetic Activity

In a protein-reducing sugar model, the sunflower sprout exhibited the strongest inhibitory effects against the formation of advanced glycation end products (AGEs) (Sun et al. 2012). At a concentration of 1.0 mg/ml, its inhibitory rate achieved 83.29 %, which was stronger than that of aminoguanidine (1 mM), a well-known

synthetic antiglycative agent (with an inhibitory rate of 80.88 %). The antioxidant capacity of sunflower sprout was also much stronger than other sprout samples in terms of free radical scavenging and reducing properties. An active ingredient contributing to the observed activities was identified as cynarin (1,5-dicaffeoylquinic acid). Given the key roles of AGEs and oxidation in the pathogenesis of diabetes, the sunflower sprouts rich in cynarin may be regarded as a beneficial food choice for diabetic patients.

Antihypertensive Activity

Sunflower seed proteins were found to be a potential source of angiotensin I converting enzyme (ACE) inhibitory peptides when hydrolyzed with pepsin and pancreatin (Megías et al. 2004). This ACE inhibitory peptide had the sequence Phe-Val-Asn-Pro-Gln-Ala-Gly-Ser and corresponded to a fragment of helianthinin, the 11S globulin from sunflower seeds.

An arginase inhibitor was isolated from sunflower seeds (Reifer and Morawska 1963). Animal studies reported that treatment with arginase inhibitor could improve vascular function and lower hypertension (Bagnost et al. 2008, 2010) and ameliorate endothelial dysfunction in cardiovascular disorders (Pokrovskiy et al. 2011).

Antihypercholesteromic Activity

Sunflower oil of any kind has been shown to have cardiovascular benefits. Numerous animal and clinical studies suggested that diets combined with a low-fat content and high levels of oleic acid lowered cholesterol which, in turn, mitigated the risk of heart disease. Dietary studies of adult men and women showed that two test diets, one rich in high-oleic- and low-erucic-acid rapeseed oil (total energy content of fat, 38 %; saturates, 12.4 %; monounsaturates, 16 %; n-6 polyunsaturates, 6 %; and n-3 polyunsaturates, 2 %) and another rich in sunflower oil (total energy content of fat, 38 %; saturates, 12.7 %; monounsaturates, 10 %; n-6 polyunsaturates, 13 %; and n-3

polyunsaturates, 0 %), reduced serum total cholesterol (TC) and low-density lipoprotein (LDL) cholesterol levels from baseline (Valsta et al. 1992). Very low-density lipoprotein (VLDL) cholesterol and total, VLDL, and LDL triglyceride levels were lower during the sunflower oil diet compared with the rapeseed oil diet. Total high-density lipoprotein (HDL) cholesterol levels remained unchanged by both diets. The consumption of rapeseed oil resulted in a more favourable HDL2 to LDL cholesterol ratio and an apolipoprotein A-I to B ratio. Another randomized crossover dietary intervention study of 14 healthy males (35–55 years old) and 14 healthy postmenopausal women (50–60 years) reported that a monounsaturated enriched sunflower oil (MO) diet (40–42 % of energy from fat, with 26–28 % from monounsaturated fat and 40–45 % of energy from carbohydrate) resulted in slower oxidation of LDL and higher HDL cholesterol, suggesting that the MO diet could decrease CHD risk compared to the low-fat, high-carbohydrate diet (22–25 % of energy from total fat, 7–8 % of energy from monounsaturated fat and 55–60 % of energy from carbohydrate) (Ashton et al. 2001). A randomized ABB/BAA extra-period crossover study of 15 men and women aged 35–69 by Allman-Farinelli et al. (2005) found that a diet rich in high-oleic-acid sunflower oil favourably altered low-density lipoprotein cholesterol, triglycerides and fasting factor VII coagulant activity. A significant increase in both plasma phospholipid and neutral lipid oleic acid occurred on the MUFA (sunflower) diet. Sunflower oil presented another useful source of MUFA for diets aimed at prevention of heart disease.

Feeding studies of male Syrian golden hamsters showed that monounsaturated fatty acid (MUFA)-rich dietary fats, for example, 18:1-rich sunflower oil, rapeseed oil and olive oil, were comparable in their hypocholesterolemic potential and caused similar effects on plasma cholesterol as polyunsaturated (PUFA)-rich oils (18:2-rich sunflower oil) when the dietary cholesterol intake was moderate (Trautwein et al. 1999). A double-blinded, randomized, three-period crossover, controlled feeding study of

adults suggested that a balanced diet in which small quantities of saturated fats replaced with sunflower oil had detectable cholesterol-reducing benefits (Binkoski et al. 2005). Total cholesterol decreased 4.7 % and low-density lipoprotein cholesterol decreased 5.8 % on the sunflower oil diet versus the average American diet. There was no effect of the experimental diets on triglyceride levels, rate of oxidation, total dienes, lipid hydroperoxides or alpha-tocopherol. The fact that there were no differences in the resulting oxidation products suggested there were no adverse effects on low-density lipoprotein oxidation. Thus, the results suggested that lower cholesterol levels can be attained by balances of polyunsaturated and monounsaturated fatty acids and sunflower oil may help with this balance.

Sunflower protein hydrolysates were found to decrease the micellar cholesterol solubility from bile acids and therefore may reduce in vivo cholesterol absorption (Megías et al. 2009). It was shown that a combination of different characteristics such as peptide size or hydrophobicity may be responsible of the inhibitory activity of generated peptides.

Skin Moisturizing Activity

Studies reported that topical application of 9 botanical extracts including sunflower oleodistillate improved skin hydration, reduced the transepidermal water loss and/or promoted keratinocyte differentiation in humans in vivo (Casetti et al. 2011). The authors concluded that the botanical extract displayed skin-barrier-reinforcing properties that may be used in dermocosmetics for dry skin.

Proteinase Inhibitory Activity

Sunflower seed was found to contain high amount of trypsin inhibitor (Roy and Bhat 1974). Two proteinaceous cysteine proteinase inhibitors (cystatins) referred to as Sca and Scb were homogenously purified from sunflower seeds (Kouzuma et al. 1996). The proteins Sca and Scb

consisted of 83 and 101 amino acid residues with $M(r)$ of 9,330 and 11,187, respectively. Papain and ficin were strongly inhibited by both Sca and Scb. Rat cathepsin H was inhibited strongly by Scb and slightly by Sca. One major and two minor groups of trypsin inhibitors were identified in sunflower seeds; the former also inhibited chymotrypsin (Konarev et al. 2000). Three groups of trypsin/subtilisin inhibitors were also present in seeds, together with three inhibitors of ficin. The molecular weights of two trypsin inhibitors were determined to be about 1,500 and 2,500, while the three trypsin/subtilisin inhibitors varied from about 1,500–6,000. Sunflower trypsin inhibitor-1 (SFTI-1) a bicyclic peptide trypsin inhibitor from sunflower seeds comprised 14 amino acid residues with one disulfide bond and a cyclic backbone and was deemed as the most potent known Bowman–Birk trypsin inhibitor and the only naturally occurring cyclic one (Korsinczky et al. 2001; Marx et al. 2003). Both the cyclic and acyclic variants of SFTI-1 inhibited trypsin with very high potencies. Enzymatic cyclization of SFT-1 afforded an acyclic permutant of SFTI-1 designated SFTI-1[6,5], which also functioned as an inhibitor of trypsin and which could be enzymatically backbone-cyclized by incubation with bovine beta-trypsin.

Allergy Problem

Sesquiterpene lactones (STL) of the sunflower, occurring in fragile multicellular capitate glandular hairs, were shown to display marked sensitizing capacity in guinea pigs (Hausen and Spring 1989). The strongest response was induced by the hemiketal form of 1-*O*-methyl-4,5-dihydroniveusin A. The STL content of 50 capitate glands was sufficient to elicit a marked response in the guinea pigs. The authors asserted that touching a sunflower plant (with up to 1,000 capitate glands per cm²) may lead to the release of sufficient STL to sensitize humans, and these substances could be considered to be responsible for the cases of allergic contact dermatitis described in sunflower growers since 1906. Four allergens named allergens a, b, c and d were puri-

fied from sunflower pollens (de la Hoz et al. 1994). Under native conditions, allergen a has a mol. mass of 32, allergen b has one of 24 and allergens c and d each have one of 55 kDa. Cross-reactivity among the four allergens and with the whole extract was very high, and each allergen recognized IgE in a high proportion of patients sensitized to sunflower pollen. In a study of the general population living in sunflower-growing regions suffering from seasonal summer allergy, cross-reactivity studies between *H. annuus* and other Compositae suggested that sunflower pollen was the main allergen involved in the hypersensitivity reaction of those patients (Jiménez et al. 1994). Bronchial challenge tests performed on 8 of the 32 patients confirmed the clinical implication of *Helianthus* pollen in suspected subjects. Thirteen patients with RAST values \geq class 2 showed 2 IgE-binding fractions at 34.0 and 42.8 kDa in 65 % of sera and 3 IgE-binding fractions at pI 4.9, 9.6 and 10.2 in 54 % of sera. A 34-kDa major allergen was purified.

The sunflower seed methionine-rich 2S albumin (SSA) was found to be an IgE-binding protein responsible for anaphylactic reactions in some sunflower seed-sensitive subjects (Kelly and Hefle 2000). Thus, subjects allergic to sunflower seed whose IgE binds to SSA are at risk of developing allergic reactions if they consume SSA. Sunflower seed was found to contain several IgE-binding proteins ranging in size from 10 to 50 kDa, including regions of the high-methionine 2 S albumin SFA-8/SSA (Kelly et al. 2000). The methionine-rich 2 S albumin seed protein from sunflower was found to be allergenic (Pantoja-Uceda et al. 2002).

Phytotoxic/Allelopathic Activity

Phytotoxic/allelopathic chemicals from sunflowers can be used as a source of biological herbicides for pest management in sustainable agriculture (Macías et al. 1996b). The biological activity of annuithrin, a germacranolide, was confirmed by growth inhibition in straight-growth tests (Spring et al. 1981). Sesquiterpene lactones niveusin C

(1) and 15-hydroxy-3-dehydrodesoxyfruticin (II), isolated from sunflower leaves, strongly inhibited indole-3-acetic acid (IAA)-induced elongation growth of *Avena sativa* L. coleoptile segments and *Helianthus annuus* L. hypocotyl segments (Spring and Hager 1982). Heliangolides from sunflower, niveusin B and its ethoxy derivative exhibited inhibitory activity in the *Avena* coleoptile tests (Spring et al. 1982a).

All five guaianolides, annuolides A–E, from sunflower leaves, possessed potential allelopathic activity, in particular over dicotyledon species when tested for their effects on the germination and growth of the dicotyledon *Lactuca sativa* and the monocotyledon *Hordeum vulgare* species (Macías et al. 1993a, b). Allelopathic bioassay suggested that the sesquiterpenes heliannuols B–D may be involved in sunflower defense against dicot plants (Macías et al. 1994). Sunflower guaianolides generally had no effect on the germination and growth of *L. sativum* and *Lycopersicon esculentum*, except for C-10 epimers 8 β -angeloyloxycumambranolid and annuolide G where inhibitory effects were found on the shoot length of *L. esculentum* (Macías et al. 1996a). The conformational changes due to functionalization within germacranolides influenced principally root and shoot growth. Heliangolides exerted greater effect on root and shoot length of dicotyledon species, presumably due to conformational flexibility and the presence of electrophilic groups.

Five flavonoids (the flavonol tambulin, the chalcones kukulcanin B and heliannone A and the flavanones heliannones B and C) were found to influence, principally, the shoot growth of *Lycopersicon esculentum* and *Hordeum vulgare* seedlings, but germination and radical length were affected by the chalcones (Macías et al. 1997). Three ionone-type bisnorsesquiterpenes annuionones A–C and the norbisabolene, helinorbisabone, isolated from sunflower exhibited clear selectivity (parameters and species) with monocotyledon species with an average of inhibition of -45 % on the germination of *Allium cepa* and an average of stimulation of 50 % on the root growth of *A. cepa* and *Hordeum vulgare*

in a range of concentrations of 10^{-5} – 10^{-9} (Macías et al. 1998b).

From an aqueous sunflower leaf extract, six new heliannuols were isolated: three 7,10-heliannanes, heliannuols F (1), I (4) and J (5), and three 7,11-heliannanes, heliannuols G (2), H (3) and K (6) (Macías et al. 1999c). The sesquiterpenes heliannuol A and helibisabonol A and the sesquiterpene lactone leptocarpin, from the leaves, inhibited the growth of etiolated wheat coleoptiles (Macías et al. 2002b). Annuionone H from sunflower leaves was found to be a potent plant growth inhibitor that could be exploited for the development of an herbicide model (Anjum and Bajwa 2005). Helivypolide F and 15-hydroxy-3-dehydrodeoxyfruticin, isolated from the leaves, were found to be the most phytotoxic when assayed in standard target species (STS) (*Lepidium sativum*, *Allium cepa*, *Lactuca sativa*, *Lycopersicon esculentum* and *Triticum aestivum*) from 5×10^{-4} to 10^{-5} M (Macías et al. 2006a). Both compounds possessed a carbonyl group at C-3 conjugated with two double bonds. Helikauranoside A, from sunflower aerial parts, was found to be the most active (–84 % at 10^{-3} M; –56 % at 10^{-4} M) in the etiolated wheat coleoptile bioassay (Macías et al. 2008). The results suggested that this compound may be involved in defense mechanisms of sunflower.

Traditional Medicinal Uses

Sunflower seeds have diuretic and expectorant properties and have been employed with success in the treatment of bronchial, laryngeal and pulmonary infections, coughs and colds in traditional medicine (Grieve 1971; Bown 1995; Foster and Duke 1998). In Europe, sunflower has been used as a treatment for pulmonary infections; a preparation of the seeds has been widely used for cold and coughs. Sunflower has been used in Chinese folk medicine for treatment of hypertension, carcinoma of stomach and asthma. In China the seeds are administered in dysentery. A tincture prepared from the seed, with rectified spirit of wine, is employed for intermittent fevers and

ague, in place of quinine. In the Caucasus, the seeds have served as a substitute for quinine in the treatment of malaria. The flowering head and seeds are febrifuge, nutritive and stomachic. A tea made from the flowers is used in the treatment of malaria and lung complaints. An infusion of the flowers has been used to kill flies. A tincture of the flowers and leaves has been recommended in combination with balsamics in the treatment of bronchiectasis. A tincture of the bark and flowers is employed for intermittent fevers and fevers that are not responsive to quinine. Sunflower oil is used in aromatherapy. In Portugal, sunflower pith has been used in making moxa, which was used in the cauterization of wounds and infections.

The leaves have astringent, diuretic and expectorant properties. A tea made from the leaves is used in the treatment of high fevers, and the crushed leaves are used as a poultice on sores, swellings, snakebites and spider bites. In Brazil the leaves are used as a substitute for *Datura stramonium* in the treatment of asthma. A decoction of the roots has been used as a warm wash on rheumatic aches and pains and as a remedy for diabetes mellitus.

In North America, sunflowers were widely used by the various native tribes for a myriad of ailments (Moerman 1968). The plant was used as a ‘spider medicine’ and dermatological aid. A sunflower infusion was used for chest pains and pulmonary disorders; the plant was used as a disinfectant to prevent prenatal infections caused by solar eclipse. Sunflower seeds were used as appetite stimulant and a dry seed decoction eaten by women to protect suckling children. A salve of pulverized seeds and root is used to prevent injury from a horse falling on a person. A poultice of the roots is used to treat snakebites and root decoction used to alleviate rheumatism. A flower infusion was used for kidney ailments. Powdered sunflower leaves were used alone in an ointment on sores and swellings. A poultice of warm ashes was applied on the stomach for worms and leaf decoction used for high fevers and as a wash for horses’ sores caused by screwworms. The Zuni men cured rattle snakebites by chewing the

fresh or dried roots and then sucking the wounds (Camazine and Bye 1980).

Other Uses

Sunflower is cultivated for its seed, which is primarily processed into an edible and industrial oil, and for food and birdseed. The seed is also processed into flour. Varieties used for non-oil-seed purposes are characterized by a larger seed size and require slightly different management practices. During processing, seed is divided into (1) larger seed for in-shell roasting, (2) medium for dehulling and (3) small for birdseed. Sunflower oil has been used in certain paints, varnishes, candles and plastics because of good semidrying properties without colour modification associated with oils high in linolenic acid. In eastern Europe and the USSR where sunflower oil is plentiful, the oil is used commonly in the manufacture of soaps and detergents (Putnam et al. 1990). Sunflower oil is also used as a carrier oil for aromatherapy, as a pesticide carrier and in the production of agrochemicals, surfactants, adhesives, plastics, fabric softeners, lubricants and coatings.

Sunflower oil contains 93 % of the energy of US number 2 diesel fuel (octane rating of 37) and has been extensively researched for its potential as an alternate biofuel source in diesel engines (Putnam et al. 1990). Blends of sunflower oil and diesel fuel are expected to have greater potential than the burning of pure vegetable oil. Recent research has emphasized on improvement in the transesterification process of sunflower oil to produce biodiesel. Ethyl acetate was employed as an acyl acceptor for immobilized lipase-catalyzed preparation of biodiesel from crude sunflower oil (Modi et al. 2007). The maximum yield of ethyl esters was 92.7 % with crude sunflower oil under optimum conditions. Pessoa et al. (2010) employed enzymatic transesterification of ethanol (ethanolysis) of the sunflower oil for production of biodiesel. Enzymatic transesterification of sunflower oil to biodiesel was conducted in a solvent-free system (Ognjanovic et al. 2009). The use of methyl acetate as an acyl receptor in a solvent-free condition resulted in high fatty acid methyl ester

(FAME) yield (95.65 %) and increased the half-life of the immobilized lipase by about 20.1 times as compared to methanol as an acyl receptor. Umdu and Sekir (2012) found that transesterification of sunflower oil at 50 °C and methanol/oil molar ratio of 9, 85 % CaO/Al₂O₃ sol-gel showed the highest biodiesel yield, ~96.6 %, but 60 % CaO/Al₂O₃ had the highest turnover frequency, 0.028 s^{−1}. Tsai et al. (2013) used non-catalytic transesterification of refined sunflower oil with supercritical methanol, in the presence of carbon dioxide for biodiesel production. The FAME yield could be achieved up to about 0.70 at 593.2 K and 10.0 MPa in 23 minutes with methanol–oil of 25:1 in molar ratio.

The plant is also a popular ornamental and a good bee foraging plant. It is also cultivated as a silage plant, especially in Central Europe. The cake remaining after the seeds have been processed for oil is used as a livestock feed. Non-dehulled or partly dehulled sunflower meal has been substituted successfully for soybean meal in isonitrogenous (equal protein) diets for ruminant animals, as well as for swine and poultry feed (Putnam et al. 1990).

Studies showed that sunflower cake (SFC) being a natural composite has potential to be used as a plastic substitute (Geneau-Sbartai et al. 2008). SFC contains several components like lignocellulosic fibres [40 %/dry matter (DM)], which essentially come from the husk of sunflower seed, that can act as fillers. It also has other biopolymers like globulins (30 % of the 30 % of sunflower seed proteins/DM of SFC) that can be shaped as a thermoplastic-like material. These proteins have also viscoelastic properties. Moreover, SFC has similar rheological properties and other physicochemical properties compatible with shaping or moulding behaviours of plastic-processing machinery. Studies reported that sunflower oil cake could be used without any additives to make biodegradable, water-resistant and exceptionally cheap mouldable composite materials (Rouilly et al. 2006). Sunflower oil cake has potential for biomethane production (Fernández-Cegrí et al. 2012). The overall methane yield was highest for sunflower oil cake pretreated hydrothermally at 100 °C; however,

this value was only 6.5 % higher than that achieved after pretreatment at 25 °C.

The stems are used as a source of cellulose and for the production of fiber mats and a high-quality writing paper. The Chinese have used this fibre for the manufacturing of fabrics. Other countries are experimenting with the use of fibre in paper. The pith of the stems is used for purposes such as making lifesaving appliances and slides for microscopes. Pectin is obtained from the receptacle and straw. The dried stems make an excellent fuel; the ash is rich in potassium and is returned to the soil. Both the dried stems and the empty seed receptacles make excellent kindling material. The seed hulls could be used for litter for poultry or returned to the soil or composted. In Russia, the hulls are utilized in manufacturing ethyl alcohol and furfural, in lining plywood and in growing yeast.

Sunflower also produces latex and is being researched to improve their suitability as an alternative crop for producing hypoallergenic rubber. A yellow dye is obtained from the ray flowers. A purple and a black dye were obtained from the seed of certain varieties that were grown by the Hopi Indians of S.W. North America to dye basketry materials. Sunflowers can be grown as a spring-sown green manure; they produce a good bulk of material. Phytotoxic/allelopathic chemicals from sunflowers can be used as a source of biological herbicides for pest management in sustainable agriculture (Macías et al. 1996b).

Sunflower chemicals have insecticidal properties. Sunflower floral chemicals with feeding deterrence for adult western corn rootworm, *Diabrotica virgifera virgifera*, decreased in the order sesquiterpenes >> diterpenes > flavonoids > dicaffeoylquinic acids (Mullin et al. 1991). Argophyllin A and 3-*O*-methylniveusin A, both sesquiterpene lactone angelates, were the most potent. The diterpenoid acid grandifloric acid and its 15-angelate and the flavonoids nevadensin and quercetin β -7-*O*-glucoside were much poorer antifeedants, although more abundant components of sunflower. The highly active antifeedant germacranolide angelates exhibited structural features and injected neurotoxic symptoms in adult rootworm similar to picrotoxinin, a gamma-aminobutyric acid-gated chloride

channel antagonist, suggesting a link between sesquiterpene neurotoxicity and GABA. Sesquiterpenes from sunflower flowers germacranolides 3-*O*-methylniveusin A and 1,10-*O*-dimethyl-3-dehydroargophyllin B diol, the eudesmanoic acid eudesma-1,3,11(13)-trien-12-oic acid and the diterpene 7-oxo-trachyloban-15 α , 19-diol and hydroxy-4,6,4'-trimethoxyaurone were strongly antifeedant to adult western corn rootworm, *Diabrotica virgifera virgifera* (Alfatafta and Mullins 1992). Seven sesquiterpene lactones 4,5-dihydroniveusin A, argophyllin B, argophyllin A, 15-hydroxy-3-dehydrodesoxytetrifruticin, niveusin B, 1,2-anhydridoniveusin A, and an unidentified epoxide, from sunflower leaves, exhibited antifeedant activity on western corn rootworm, *Diabrotica virgifera virgifera* (Chou and Mullin 1993). Lipids in sunflower pollens rich in omega-3 linolenic acid including triglycerides, free fatty acids, phosphatidylethanolamines, phosphatidic acids and phosphatidylcholines were highly phagostimulatory to the adult western corn rootworm *Diabrotica virgifera virgifera* (Lin and Mullin 1999). Other important phagostimulatory components included a hydroxycinnamic acid-polyamine amide, N(1),N(5),N(10)-tri[(*E*)-*p*-coumaroyl]spermidine and a flavonol, quercetin β -3-*O*-glucoside.

Biodegraded products of sunflower flower heads (BPSH) were found to be useful for plant growth (Kaya et al. 2006). Growth of *Phaseolus vulgaris*, *Cicer arietinum* and *Triticum vulgare* seedlings was enhanced at a concentration of 10 % BPSH and decreased at 100 % concentration. As a result, at concentrations up to 10 %, the product was found to be beneficial for growth of plants. A bioactive compound with antibacterial activity was isolated and purified from sunflower leaf extract (Sankaranarayanan et al. 2008). It showed activity against *Xanthomonas oryzae* pv. *oryzae* and induced auxin, gibberellins and cytokinin in *Oryza sativa* and *Phaseolus mungo*.

Comments

Leading sunflower seed-producing countries (in tonnes production) are the following: Russian Federation (9,697,450), Ukraine (8,670,500),

Argentina (3,671,750), France (1,882,450), Romania (1,789,330), China (1,700,000), Bulgaria (1,439,700), Hungary (1,374,780), Turkey (1,335,000), Spain (1,084,300) and the United States (924,550) (FAO 2012).

Origin/Distribution

Matricaria chamomilla is native to southern and eastern Europe and northern and western Asia. It has been introduced elsewhere and has naturalized in North America and Australia.

Agroecology

German chamomile is a cool climate species, growing in areas with temperatures of 7–26 °C and mean annual rainfall of 400–1,400 mm per season. It is frost tolerant down to –12 °C. It grows best in full sun and requires long summer days and high heat units for optimum essential oil yield (Alberts 2009). Optimum oil yields were found in temperature range of 20–26 °C, but increasing temperature had a negative impact on individual flower-head weight and days from buds to full-opened flowers (Bettray and Vömel 1992). Chamomile is not fastidious of soil types but thrives best on a well-drained, sandy or sandy-loam soils and

tolerates pH from 4.8 to 8.5. It will also grow on clayey lime soils as it has a great tolerance to soil alkalinity.

Edible Plant Parts and Uses

German chamomile is cultivated for its essential oil and dried flowers. The oils are used as agents in alcoholic beverages, confections, desserts, perfumes, aromatherapy and cosmetics. Dried flowers are used for aromatic and soothing herbal teas and blend with other teas, in syrups and fruit jelly (Roberts 2000).

Botany

Chamomile is an erect, aromatic, herbaceous annual, 15–80 cm high with a much branched, light green stem. The leaves are alternate, bipinnate or tripinnate with long and linear pinna, mildly pubescent to glabrous (Plate 1). Flowers are borne in solitary terminal capitula, 10–20 mm across, on 15–25 cm grooved peduncle (Plate 1). The receptacle is 6–10 mm wide; is hollow, swollen and obovoid to subglobose; and lacks involucre scales and paleae. The ray florets are ligulate, white 6–10 mm by 2.5–3.5 mm. The central disc florets are bisexual, tubular with 5-teeth, 1.5–2.5 mm long, yellow. The fruit is a yellowish brown cypsela with 3–5 faint ribs.

Nutritive/Medicinal Properties

Proximate nutrient composition per 100 g of brewed chamomile herbal tea was reported as follows: water 99.70 g, energy 1 kcal (4 kJ), carbohydrate 0.2 g, Ca 2 mg, Fe 0.08 mg, Mg 1 mg, K 9 mg, Na 1 mg, Zn 0.04 mg, Cu 0.015 mg, Mn 0.044 mg, F 13 µg, thiamine 0.010 mg, riboflavin 0.004 mg, pantothenic acid 0.011 mg, total folate 1 µg, total choline 0.4 mg, β -carotene 12 µg, vitamin A 1 µg RAE, vitamin A 20 IU, total saturated fatty acids 0.002 g, total monounsaturated fatty acids 0.001 g and total polyunsaturated fatty acids 0.005 g (USDA 2012).

Plate 1 Chamomile flowers and foliage

Other Flower Phytochemicals

Five organic acids were isolated from chamomile flowers: tartaric acid, citric acid, malic acid, malonic acid and succinic acid (Olennikov and Tankhaeva 2005). Mann and Staba (1986) had listed an extensive range of phytochemicals found in chamomile. The main constituents of chamomile flowers included several phenolic compounds, primarily the flavonoids apigenin, quercetin, patuletin, luteolin and their glucosides (McKay and Blumberg 2006). The principal components of the essential oil extracted from the flowers were the terpenoids α -bisabolol and its oxides and azulenes, including chamazulene.

The following chemicals were reported in chamomile flower heads: ascorbic acid, thiamine, niacin, polyphenols (quercetin, rutin, geraniol, gallic acid, tannin, catechin tannic, caprylic acid, kaempferol, thujone) and fatty acids (oleic, linoleic, palmitic, sinapic) (Mann and Staba 1986).

The terpenoids (–)- α -bisabolol oxides A, B and C were isolated from chamomile extract (Schilcher et al. 1976). Two spirocyclic polyines, the isomeric *cis* (Z)-enyne dicycloether *cis*-2-[hexadiyne]-(2,4)-ylidene]-1,6-dioxaspiro-[4,4]-nonene) and *trans* (Z)-enyne dicycloether *cis*-2-[hexadiyne]-(2,4)-ylidene]-1,6-dioxaspiro-[4,4]-nonene), were found in chamomile flowers (Bohlmann et al. 1961). The following phenyl carboxylic acids, synergic, vanillic, anisic and caffeic acids, were found in both ligulate and tubular chamomile florets (Reichling et al. 1979). Chamomile flower heads were also reported to contain *cis/trans*-en-in-dicycloethers (polyines) (Gasic et al. 1983), anthecotulid (37–120 mg/g) (Hausen et al. 1984) and up to 0.3 % choline (Bayer et al. 1958). In chamomile flowers from different origins, a range of 37.4–98.5 mg/100 g of herniarin and 6–17.8 mg/100 g of umbelliferone were determined (Schilcher and Kamille 1987). The average content in ligulate florets was significantly higher than in the tubular florets. The following coumarins, herniarin, umbelliferone, esculetin, isoscoupoletin and scopoletin, were isolated from chamomile flowers (Kotov et al. 1991). A flavone 7-*O*-glucoside-specific glucosidase was purified and characterized from ligulate florets of *Chamomilla recutita*, and salicin, arbutin, naringenin 7-*O*-glucoside, luteolin 5-*O*-glucoside, and various *p*-nitrophenol compounds ($-\beta$ -D-glucoside, $-\beta$ -D-galactoside, $-\beta$ -fucoside and a nitrophenyl- β -D-glucoside) were also isolated from the florets (Maier et al. 1993). The enzyme was confirmed to have a high affinity towards flavone 7-*O*-glucosides. Aqueous alcohol extracts of chamomile flowers were found to contain the following fat soluble compounds: β -farnesene (0.04–0.28 %), bisabolone oxide (<0.01–0.05 %), bisabolol oxide-A (0.15–0.59 %), spiroether (0.3–1.03 %) and pentacosane (0.08–0.11 %) (Kanamori et al. 1992). Two phenylpropanoids and one flavonoid glycosides were isolated from a 1-butanol-soluble portion of chamomile flowers (Kanamori et al. 1993). Their structures were elucidated as *cis*-2- β -D-glucopyranosyloxy-4-methoxy cinnamic acid (1) and *trans*-2- β -D-glucopyranosyloxy-4-methoxy cinnamic acid (2) and cosmosiin (apigenin-7-*O*- β -D-glucopyranoside)

(3), respectively. All 3 compounds were found in higher concentration in ligulate flowers (compound (1) 4.32 %, compound (2) 1.32 %, cosmosiin 5.20 %) than tubular flowers (compound (1) 1.07 %, compound (2) 0.52 %, cosmosiin 0.02 %) or involucre scale (compound (1) 2.56 %, compound (2) 1.05 %, cosmosiin 0.17 %). Ahmad and Misra (1997) isolated oleonic acid, β -sitosterol and β -sitosterol glucoside from the flowers by organic solvent extraction of chamomile flower oil. All three were also found in the capitulum receptacle (compound (1) 0.16 %, compound (2) 0.08 %, cosmosiin <0.01 %), stem (compound (1) 2.45 %, compound (2) 0.69 %, compound (3) 0.02 %) and leaf (compound (1) 1.75 %, compound (2) 0.67 %, cosmosiin 0.02 %). Two polyacylated spermines N1,N5,N10,N14-tetrakis[3-(4-hydroxyphenyl)-2-propenoyl]-1,5,10,14-tetraazatetradecane (tetracoumaroyl spermine) and N1,N5,N10-tris[3-(4-hydroxyphenyl)-2-propenoyl]-1,5,10,14-tetraazatetradecane were found on chamomile flower extract (Yamamoto et al. 2002). Eleven bioactive phenolic compounds, namely, coumarins, herniarin and umbelliferone; phenylpropanoids, chlorogenic acid and caffeic acid; flavones, apigenin, apigenin-7-*O*-glucoside, luteolin and luteolin-7-*O*-glucoside; flavonols, quercetin and rutin; and flavanone, naringenin, were determined in chamomile extracts (Fonseca et al. 2007). The limits of detection and quantification for apigenin were 35.0 and 150.0 μ g/ml, respectively.

The flavonoids quercetin-7-glucoside (quercimeritrin) and apigenin-7-glucoside (apigetrin) were isolated from chamomile florets (Hörhammer et al. 1963). Lipophilic flavonoids isolated from chamomile flowers included eupatoletin, eupalitin, chrysosplenol and chrysosplenitin (3,6,7,3'-tetramethyl-quercetagenin) (Hänsel et al. 1966). A new chamomile flavone apigenin 7-6''-*O*-(acetyl)-glucoside was isolated from chamomile flowers and florets and the aglyca apigenin, luteolin, patulin, quercetin and isorhamnetin and the glycoside apigenin-7-glucoside, luteolin-7-glucoside, patulitrin and quercimeritrin were identified (Kunde and Isaac 1979). They further reported the presence of flavonoid and postulated a diacetylated apigenin-7-glucoside. They classified

chamomile flavonoids according their polarity into (a) lipophilic aglyca (e.g., methoxylated compounds), (b) hydroxylated flavones aglyca, (c) acetylated flavones monoglycosides and (d) flavones diglycosides. Methylated flavonoid aglycones, eupatoletin, eupalitin and chrysosplenol, were found in the flowers (Exner et al. 1981). From ligulate flowers of *Matricaria chamomilla* were isolated a mixture of apigenin 7-*O*- β -glucoside diacetates, which was shown to be based on (2'', 3'')- and (3'', 4'')-diacetates (Redaelli et al. 1982). The flavones apigenin and its glucosides, apigenin-7-glucoside and apigenin-7-acetylglucoside, were found in ligulate florets but not in the tubular florets of *Matricaria chamomilla* (Redaelli et al. 1981b). Dried ligulate chamomile flowers contained 7–9 % glucosides of apigenin and 0.3–0.5 % free apigenin. Glucosides were identified as apigenin 7-glucoside and a 1:3 mixture of the 2''- and 6''-acetates (Redaelli et al. 1980). The most abundant flavonoid derivatives in chamomile flowers were apigenin 7-glucoside and its acetylated derivatives, as well as luteolin, quercetin and their glycosides (Carle and Isaac 1985). Beside hydroxylated aglyca, methoxylated flavonoids like chrysosplenol, jaceidin, chrysoeriol, patuletin, spinacetin, 6-methoxykaempferol, axillarin, chrysosplenetin, eupatoletin and eupalitin were identified in chamomile flowers (Carle and Isaac 1985).

Accumulation of two phenylpropanoid glycosides, (1) *cis*-2- β -D-glucopyranosyloxy-4-methoxy cinnamic acid and (2) *trans*-2- β -D-glucopyranosyloxy-4-methoxy cinnamic acid and one flavonoid glycoside, (3) cosmosiin (apigenin-7-*O*- β -D-glucopyranoside) glycosides in chamomile flower head, reach a maximum during flowering (Ohe et al. 1995). The content of (1) and (2) reached 2 % and 0.5 % in the head respectively during harvesting, and their content was higher in the ligulate flowers than tubular flowers. Coumarin, umbelliferone and its methoxy analogue herniarin were also found in *M. chamomilla* flowers (Redaelli et al. 1981a). The polyphenolic compounds identified in the methanolic flower-head extract by Mulinacci et al. (2000) included 5-caffeoylquinic acid, 3-caffeoylquinic acid, 4-caffeoylquinic acid, quinic

acid, ferulic acid-L-*O*-glycoside, caffeoylquinic acid derivative, ferulic acid-7-*O*-glycoside, quercetin-3-*O*-galactoside, quercetin-7-*O*-galactoside, patuletin-7-*O*-glucoside, dicaffeoylquinic acid derivative, 1,3-dicaffeoylquinic acid, apigenin-7-*O*-glucoside, quercetin derivative, luteolin-4'-*O*-glucoside, quinic acid derivative, apigenin-7-*O*-glucosyl-2''-acetate, apigenin-7-*O*-glucosyl-6''-acetate, apigenin-7-*O*-glucosyl-diacetate, apigenin, luteolin-7-*O*-rutinose and ferulic acid derivative.

Free and total apigenin contents in chamomile extracts were, respectively, determined as 106 and 903 $\mu\text{g/g}$ (methanolic extract), 77 and 817 $\mu\text{g/g}$ (ethanolic extract) and 11.0 and 247 $\mu\text{g/g}$ (glycolic extract) (Fonseca and Tavares 2004). The major flavonoids (apigenin glucosides) identified in the white florets of chamomile were apigenin 7-*O*-glucoside, apigenin-7-(6''-malonyl-glucoside), apigenin-7-(6''-acetylglucoside), apigenin-7-(6''-caffeoyl-glucoside), apigenin-7-(4''-acetyl-glucoside), apigenin-7-(4''-acetyl,6''-malonyl-glucoside) and a partially characterized apigenin-7-(mono-acetyl/mono-malonylglucoside) isomer (Svehlikova et al. 2004). The bioactive principles in the ethanol/water extract of chamomile flowers were determined as *cis*-2- β -D-glucopyranosyloxy-4-methoxy-cinnamic acid, *trans*-2- β -D-glucopyranosyloxy-4-methoxy-cinnamic acid, apigenin-7-*O*- β -D-(6''-*O*-rhamnosyl)glucopyranoside (isorhoifolin), apigenin-7-*O*- β -D-glucopyranoside (cosmosiin), apigenin-7-*O*- β -D-(6''-*O*-acetyl)glucopyranoside, 7-Methoxycoumarin (herniarin) and 4',5,7-trihydroxyflavone (apigenin) (Weber et al. 2008). The following flavonoids, kaempferol, quercetin, myricetin and isorhamnetin, were isolated from the ethanol chamomile flower extract (Mohamed 2010).

The main secondary metabolites of *Matricaria chamomilla* ligulate flowers were apigenin-7-*O*-glucoside derivatives and (*Z*)-2- β -D-glucopyranosyloxy-4-methoxy cinnamic acid and (*E*)-2- β -D-glucopyranosyloxy-4-methoxy cinnamic acid (GMCAs), the precursors of herniarin (Repčák and Krausová 2009). The flavonoids detected were apigenin 7-*O*-glucoside, apigenin 7-*O*-(6''-malonyl)-glucoside, apigenin 7-*O*-(4''-acetyl)-glucoside,

apigenin 7-*O*-(6''-caffeoyl)-glucoside, apigenin 7-*O*-(6''-acetyl)-glucoside, apigenin 7-*O*-(4''-acetyl, 6''-malonyl)-glucoside, and apigenin. The content of the apigenin glucoside and its main acylated derivatives in ligulate flowers of diploid plants were found to be significantly higher before the start of flowering in comparison with tetraploid plants. During the flowering and post-flowering phase, their content decreased and no difference between diploid and tetraploid plants was observed. The (*E*)-isomer was the dominant form of 2-β-D-glucopyranosyloxy-4-methoxy cinnamic acid. These secondary stress metabolite precursors were accumulated in higher concentrations in young growing ligulate flowers, but during flowering and post-flowering phases, their content decreased. Significantly higher content was found in tetraploid plants in comparison with diploid plants. Aglycones of glycosides were found in low concentrations.

Two new flavonoids quercetin and isorhamnetin besides myricetin and kaempferol were detected in the ethanolic extract of the flower head of *Matricaria chamomilla* growing in Iraq (Mohamed 2010). The most abundant phenolic compounds in both chamomile flowers and chamomile tea extracts were chlorogenic acid, umbelliferone, apigenin and apigenin-7-glucoside (Nováková et al. 2010). In chamomile tea extracts, there was greater abundance of flavonoid glycosides such as rutin or quercitrin, while the aglycone apigenin and its glycoside were present in lower amounts. The total content of polyphenols (in chlorogenic acid equivalents) in chamomile teas showed a significant variability as well as content of total flavonols (0.29–1.21 %) or total phenolic acids (7.7–91.4 mg/200 ml). (Raal et al. 2012). The major phenolic compounds in chamomile tea infusions were chlorogenic acids, ferulic acid glycosides, dicaffeoyl quinic acids and apigenin glycosides. Based on the amounts of essential oil, terpenoids, total flavonols and major phenolic compounds, the quality of the commercial chamomile teas was very variable, and the chamomile teas available in pharmacies should be preferred for the medical purposes. The major polyphenols detected were neochlorogenic acid; chlorogenic acid;

cryptochlorogenic acid; ferulic acid glucoside 1; ferulic acid glucoside 2; quercetin galactoside; quercetin glucoside; luteolin glucoside; 3,4-dicaffeoyl quinic acid; 3,5-dicaffeoyl quinic acid; 4,5-dicaffeoyl quinic acid; apigenin glucoside; and apigenin acetylglucoside.

Farnesene, bisabolol, azulene (chamazulene), bisabolol oxide and terpene alcohol (farnesol) were the major constituents of the essential oil from dried chamomile flowers (Mishra et al. 1999). Oil from fresh flowers contained a high amount of terpene alcohol which decreased in shade-dried flowers and was the lowest in sun-dried flowers. The bisabolol content was the highest in sun-dried and minimum in fresh flowers. Farnesene content was higher in shade-dried flowers; bisabolol and azulene were higher in sun-dried flowers. The bisabolol oxide content was comparatively higher in fresh flowers (10.4 %) and was the least (8.4 %) in shade-dried flowers. The essential oil of chamomile inflorescence developed from callus cultures was found to contain chamomillol, gossonorol, cubenol, α-cadinol, (–)-α-bisabolol, 1-azulenethanol acetate and (–)-α-bisabolol acetate (Magiatis et al. 2001).

The Brazilian chamomile flower essential oil contained the following major components: bisabolol oxide B (23 %), bisabolol oxide A (17 %), (*Z*)-β-farnesene (16 %), α-bisabolol (13 %), chamazulene (8 %) and chamo-spiroether (5 %) (Matos et al. 1993). Studies in Yugoslavia found the chamomile essential oil content ranged from 0.24 to 0.50 % (Mimica-Dukic et al. 1993). The main compound in all samples was bisabolol oxide A (33.46–48.48 %); other major compounds were (–)-α-bisabolol, bisabolol oxide B, bisabolon oxide, farnesene, spathulenol, chamazulene, as well as en-in-dicycloether. Thirty-four compounds were identified in chamomile flower essential oil from Cuba, of which α-bisabolol oxide A (23.3 %), chamazulene (14.1 %), α-bisabolone oxide A (13.4 %) and β-caryophyllene (10.4 %) were the main constituents (Pino et al. 2000). Eighty compounds were identified in chamomile essential oil from Iran, of which α-bisabolol oxide A (43.8 %), α-bisabolone oxide A (13.6 %) and β-bisabolene (19.6 %) were predominant (Pino et al. 2002). Thirty-seven

components were found in the essential oil distilled from the flower heads in Eastonia (Orav et al. 2001). Oxygenated sesquiterpenes were the most characteristic chamomile essential oil components comprising 50–70 % of the total oil, among which bisabol oxide A accounted for 20.2 %–33.1 %, bisabolon oxide A 6.7–13.6 %, bisabolol oxide B for 7.9–12.4 % and α -bisabolol 2.9–7.8 %. Chamazulene represented 5.3–7.2 % and en-yn-dicycloether contributed 17.1–21.7 % of the total oil. Sesquiterpenes (5–16 %) mainly comprised (*E*)- β -farnesene (4.3–12.6 %). Monoterpenes and oxygenated monoterpenoid compounds contributed very little (<1 %) to the chamomile oil composition. The minor components included α -pinene trace (tr), sabinene tr 0.1 %, 6-methyl-5-hepten-2-one 0.1 %, myrcene tr 0.1 %, 1,2,4-trimethylbenzene tr 0.1 %, 3-octanol 0.1–0.2 %, *p*-cymene tr 0.1 %, 1,8-cineole 0.1 %, limonene 0.1 %, (*E*)- β -ocimene tr 0.1 %, Artemisia ketone 0.2–0.4 %, γ -terpinene tr 0.1 %, terpinolene tr 0.1 %, terpinen-4-ol tr 0.1 %, α -terpineol tr 0.1 %, carvone tr 0.1 %, γ -elemene 0.1–0.3 %, decanoic acid 1.1–2.1 %, β -caryophyllene 0.1 %, germacrene 0.5–1.7 %, γ -muurolene 0.5–1.7 %, α -farnesene 0.3–0.9 %, β -bisabolene tr 0.7 %, γ -cadinene tr 0.1 %, σ -cadinene tr 0.1 %, (*E*)-nerolidol 0.1 %, spathulenol 2.3–3.6 %, caryophyllene oxide tr 0.2 %, T-cadinol 0.2 %, unidentified 0.1 %, and unidentified 0.5–0.9 %. Total oil yield was 1.88–2.09 mg/g. Forty-one components were identified in chamomile grown in the lower region of the Himalayas, representing 97.5 % of the oil (Sashidhara et al. 2006). The main constituents were α -bisabolol oxide A (36.5 %) and B (8.6 %), (*E*)- β -farnesene (14.0 %), α -bisabolol (16 %) and chamazulene (5.6 %). The main constituents, except for α -bisabolol oxide B, were found in higher concentration in oil from the foothills of the Himalayas than in the oil from the northern Indian plain. Eighteen volatile components were identified in the Iranian chamomile flower essential oil (Owlia et al. 2007). The major components were guaiazulene 25.6 %, (*E*)- β -farnesene 20.1 %, chamazulene 12.4 %, α -bisabolol oxide B 7.3 %, α -bisabolol 7.3 %, hexadecanol 5.6 % and

germacrene D 3.15 %. Other components included *Z*- γ -bisabolene 2.6 %, -bisabolol oxide A 1.9 %, spathulenol 1.7 %, *n*-nonadecane 1.4 %, caryophyllene oxide 1.2 %, α -muurolene 0.8 %, limonene 0.5 %, γ -terpinene 0.5 %, *n*-pentacosane 0.5 % and sclarene 0.4 %. The main compounds identified in chamomile flower essential oil were α -bisabolol (56.86 %), *trans-trans*-farnesol (15.64 %), *cis*- β -farnesene (7.12 %), guaiazulene (4.24 %), α -cubebene (2.69 %), α -bisabolol oxide A (2.19 %) and chamazulene (2.18 %) (Tolouee et al. 2010). Chamomile essential oil was found to contain 13 compounds, mainly bisabolol and its oxides, chamazulene, farnesene, germacrene and other sesquiterpenes (Hernández-Ceruelos et al. 2002). A total of 39 components were identified, representing over 92 % of the total oil yield of chamomile oils from European countries (Orav et al. 2010). The principal biologically active compounds in chamomile oils were bisabolol oxide A (3.1–56.0 %), α -bisabolol (0.1–44.2 %), bisabolol oxide B (3.9–27.2 %), *cis*-enyne-bicycloether (8.8–26.1 %), bisabolon oxide A (0.5–24.8 %), chamazulene (0.7–15.3 %), spathulenol (1.7–4.8 %) and (*E*)- β -farnesene (2.3–6.6 %). In 8 chamomile samples from 13, bisabolol oxide A (27.5–56.0 %) was predominant (among them in three Estonian samples). α -Bisabolol (23.9–44.2 %) was predominant in the samples from Moldova, Russia and the Czech Republic. The sample from Armenia was rich in bisabolol oxide B (27.2 %) and chamazulene (15.3 %). The oils were obtained in yields of 0.7–6.7 ml/kg and the minimum limit of 4 ml/kg stated by the European Pharmacopoeia was exceeded only in 13 samples from 13 analyzed drugs.

Both aqueous and methanolic chamomile flower extracts demonstrated the presence of mixture of several apigenin glucosides and parent glycone, apigenin (Srivastava and Gupta 2009). Other apigenin glucosides identified in chamomile extracts were mono-caffeoyl glucoside, mono-acetyl glucoside and mono-malonyl glucoside as well as mono-acetyl/mono-malonyl glucosides. The methanolic chamomile extract had high concentration of apigenin-7-*O*-gluco-

side along with several polyphenolic constituents which include caffeic acid, luteolin and luteolin-7-*O*-glucoside, among common flavonoids. The aqueous chamomile extract was found to contain a small fraction (5–7 % of total essential oil) content of the flower. The essential oil content in the methanolic extract consists of chamazulene, α -bisabolol, bisabolol oxides A and B, a cyclic ether and different hydrocarbons which were insoluble in the aqueous phase. Aqueous extracts obtained from both Lebanese and Egyptian chamomile varieties showed the abundance of apigenin-7-*O*-glucoside. Methanolic chamomile extract prepared from ray florets of Lebanese and Egyptian chamomile showed the presence of apigenin-7-*O*-glucoside (39 %) and the aglycone, apigenin, 6.7 % in the Egyptian and 2.3 % in the Lebanese variety. Disc florets of chamomile from Lebanese origin showed higher content of apigenin-7-*O*-glucoside (38.5 %) compared to Egyptian variety (36.1 %) but had no aglycone. Salamon et al. (2010) characterized Egyptian and Iranian chamomile landraces into 4 basic chemotypes based on the main components (%) in the essential oil:

Type A (South American collection): α -bisabolol oxide B (22.43–58.85 %) > α -bisabolol oxide A (4.74–15.68 %) > α -bisabolol (4.37–15.41 %), (en-yn-dicycloethers 2.61–11.27 %, chamazulene 2.70–17.69 %).

Type B (Egypt and central Europe): α -bisabolol oxide A (31.07–52.25 %) > α -bisabolol oxide B (5.27–18.79 %) > α -bisabolol (8.81–12.92 %), (en-yn-dicycloethers 4.08–9.90 %, chamazulene 5.40–7.95 %).

Type C (Spain/Catalonia, Malta, Crimea): α -bisabolol (24.18–77.21 %) > α -bisabolol oxide B (3.17–34.46 %) > α -bisabolol oxide A (2.13–18.50 %) (en-yn-dicycloethers 1.92–12.00 %, chamazulene 1.91–7.89 %).

Type D (southeast Europe, Turkey): α -bisabolol oxide B (10.43–24.20 %) > α -bisabolol oxide A (9.62–25.83 %) > α -bisabolol (8.49–19.58 %), (en-yn-dicycloethers 5.51–10.68 %, chamazulene 1.91–7.89 %). The highest contents of α -bisabolol oxide A and α -bisabolol oxide B in the flower antheridia were found in the Egyptian chamomile.

The total extract yield of chamomile oil obtained by solvent extraction (4.98 %) was much higher than the oil yield obtained by steam distillation even after 6 hours (0.31 %) (Falzari and Menary 2003). The oil yield increased with increasing duration of steam distillation but after 6 hours distillation the yield of solvent extract is still 16 times greater than the yield of steam distilled oil. The main volatile components of chamomile essential oil were *E*- β -farnesene (42.59 %), germacrene D (2.93 %), bicyclogermacrene (1.99 %), (*E,E*)- α -farnesene (8.32 %), α -bisabolol oxide B (4.43 %), α -bisabolone oxide A (4.53 %), chamazulene (1.18 %), α -bisabolol oxide A (21.16 %) and *cis*-ene-yne-dicycloether (5.94 %) (Heuskin et al. 2009). Other minor components included *trans*-ene-yne-dicycloether (0.99 %), (*E*)-phytol (0.23 %), globulol (0.23 %), spathulenol (0.63 %), dendrolasin (0.21 %), dehydroneolidol (0.09 %), *trans*-nerolidol (0.17 %), unidentified sesquiterpene (0.33 %), sesquirosefuran (0.18 %), δ -cadinene (0.18 %), (*Z,E*)- α -farnesene (0.83 %), β -selinene (0.22 %), unidentified sesquiterpene (0.10 %), aromadendrene (0.07 %), β -caryophyllene (0.17 %), α -gurjunene (0.04 %), sativene (0.04 %), β -elemene (0.7 %), α -isocomene (0.26 %), β -maaliene (0.07 %), α -copaene (0.04 %), 4,8-dimethylnona-3,8-dien-2-one (0.04 %), isoborneol (0.03 %), artemisia alcohol (0.06 %), artemisia ketone (0.32 %), γ -terpinene (0.17 %), *cis*- β -ocimene (0.69 %), *trans*- β -ocimene (0.11 %), limonene (0.10 %), *p*-cymene (0.11 %), 2-pentylfuran (0.05 %), 6-methyl-5-hepten-2-one (0.03 %), sabinene (0.04 %) and α -pinene (0.03 %). Precocenes and piperitone (Yaguchi et al. 2006) and (*E*)- and (*Z*)-spiroethers (Yoshinari et al. 2008) were isolated from chamomile essential oil.

The constituents of chamomile flower oil comprised oxides (59.42 %), hydrocarbons (5.88 %), ethers (11.98 %), acids/esters (3.87 %), aldehydes/ketones (0.79 %), sesquiterpene lactones (6.18 %), alcohols (2.57 %), coumarins/miscellaneous compounds (0.35 %) and unknowns (5.62 %) (Tschiggerl and Bucar 2012). The major constituents were α -bisabolol oxide A (29.92 %), α -bisabolol oxide B (21.13 %), α -bisabolone oxide A (7.87 %), β -farnesene (3.90 %), *cis*-spiroether

(11.67 %) and chamazulene (6.18 %). The major constituents of the flower infusion extract obtained by hydrodistillation were α -bisabolol oxide A (28.26 %), α -bisabolol oxide B (25.92 %), α -bisabolone oxide A (5.83 %), β -farnesene (1.10 %), *cis*-spiroether (4.69 %), chamazulene (19.11 %) and decanoic acid (1.56 %). The major constituents of the flower infusion extract obtained by solid phase extraction were α -bisabolol oxide A (22.80 %), α -bisabolol oxide B (8.09 %), α -bisabolone oxide A (1.59 %), *cis*-spiroether (25.62 %), *trans*-spiroether (6.40 %), chamazulene (1.77 %), achillin (2.88 %), matricarin/acetoxiachillin (5.20 %) and methylumbelliferone (5.55 %). Two sesquiterpene lactones leucodin (0.53 %) and acetoxiachillin were newly identified together with achillin and matricarin in the chamomile infusion extract. They found that high amounts of spiroethers (ca. 30% in the infusion as compared to ca. 12 % in the genuine oil) and coumarins (ca. 7 %) and reduced amounts of bisabolol oxides (ca. 32 % in the infusion vs. ca. 60 % in the genuine oil) can be regarded as markers of the volatile fraction of chamomile tea. Their results demonstrated that solid phase extraction or other liquid extraction methods should be preferred over hydrodistillation when characterizing the aromatic composition of infusions.

The highest essential oil content was found in fully developed flowers approximately 1 week after beginning of flowering (Franz 1980). The composition of the essential oil depended on the stage of development. Flower buds contained more hydrocarbons and (–)- α -bisabolol, whereas with development of the flowers, chamazulene and the (–)- α -bisabolol oxides increased. The content of enin-dicycloethers increased in the receptacle. In another study, the quantity of α -bisabolol, α -bisabolol oxides A and B and α -bisabolone oxide A in chamomile flower reached a maximum at full bloom and then declined (Arak et al. 1980). The farnesene content of the flower decreased gradually with flower growth and development. The qualitative composition of essential oil remained stable at all stages of flower development. Accumulation of essential oil in chamomile flowers continued during

drying, and its quantitative composition depended on the drying method. Harvesting at the early flowering phase and drying in a shaded place were recommended.

Among 30 compounds detected in dried chamomile flowers at two development stages, (*E*)- β -farnesene (49 %), artemisia ketone (10 %) and germacrene D (9 %) were the predominant volatile components in the HS-SPME (head-space solid-phase microextraction) extract, while α -bisabolol oxide A (42 %), chamazulene (21 %) and (*Z*)-spiroether (8 %) were the main essential oil constituents among the 13 compounds obtained by SDSE (steam distillation-solvent extraction) (Rafieiohlhossaini et al. 2012). (*E*)- β -farnesene was the only compound which showed significant differences between the development stages of two flowers: stage I, when ligulate flowers start to develop and tubular flowers were still closed, and stage II, when tubular flowers were partially to completely opened. Eliasová et al. (2012) found that polyamine conjugate 1*N*,5*N*,10*N*,14*N*-tetracoumaroyl spermine (tetracoumaroyl spermine) was present mainly in tubular flowers, reaching its maximal content during the 3rd phase of flowering when the corollae of tubular flowers start to open. The later observed decrease could result from a release of pollen that also contained a considerable amount of tetracoumaroyl spermine. They postulated that tetracoumaroyl spermine may play an important role in pollen development. This polyamine from chamomile flower heads could be used for the treatment of several human disorders such as depression and anxiety.

The purified mucilage from chamomile flowers yielded xylose (21 %), arabinose (10 %), galactose (15 %), glucose (7 %), rhamnose (2 %) and glucuronic acid (45 %) (Janecke and Weisser 1964, 1965). The mucilage had a degree of polymerization of approximately 27 (molecular weight 3,500–4,200) and the linkages of sugars in the mucilage were suggested to be predominantly β -glycosidic. Carle and Isaac (1985) reported that chamomile mucilage consists of fructose, arabinose, xylose, glucose, galactose, rhamnose, galacturonic acid and glucosamine and the main chain the polysaccharide tp consists of α -1 \rightarrow 4

connected D-galacturone acids. The polysaccharide was later confirmed to be methyl-glucurone oxylane (Füller et al. 1991, 1993). They also identified a neutral fructane of medium molecular mass 3,600 containing 74.3 % fructose, 3.4 % glucose (similar to inulin) and a strongly branched rhamnogalacturonane of medium molecular mass 9,300 consisting of 28 % uronic acid and 3.2 % protein (similar to pectin). These were found to have arabino-3,6-galactane glycoproteins as side chains. In an aqueous alcoholic chamomile extract, only fructanes were found.

Root Phytochemicals

The essential oil of *Matricaria chamomilla* roots contained the sesquiterpenes chamomillol, caryophyllene, caryophyllenepoxide and the polyenes Chamomillaester I and II (Reichling et al. 1984). The essential oil accumulated in schizogenous oil passages and oil cells restricted to the roots. Callus surface cultures of *Matricaria chamomilla* initiated from stems and flower heads produced an essential oil similar to that of the root. It exclusively accumulated in oil cells typical of the roots.

Plant Aerial Parts/Leaf/Cell Culture Phytochemicals

Sesquiterpenes, flavonoids, coumarins and polyacetylenes are considered the most important constituents of the chamomile drug (Schilcher and Kamille 1987). Secondary metabolites found in *M. chamomilla* included isobutyl angelate, 2-methylbutyl angelate, farnesene, β -farnesene, farnesol, (–)- α -bisabolol, bisabolol oxide A, bisabolol oxide B, matricin, chamazulene, guaiazulene, umbelliferone, herniarin, caffeic acid, chlorogenic acid, apigenin, luteolin, apigenin-7-*O*-glucoside, luteolin 7-*O*-glucoside, quercetin and *Z*-enynedicycloether.

Flavonoids found in chamomile leaves included 7-glucosides of quercetin, isorhamnetin and luteolin together with small amounts of chrysoeriol and apigenin 7-glucoside and their aglyca (Greger 1975).

Polyphenolic compounds (g/kg dry matter) in the aerial chamomile plant parts were determined as follows: chlorogenic acid 1.16 g, 3,5-DCQA (dicaffeoylquinic acid) 2.92 g, 4,5-DCQA 1.61 g, total caffeoyl derivatives 5.69 g, total dihydroxycinnamic acid derivatives 15.89 g, total flavonoids 9.48 g, total dihydroxycinnamic acid derivatives + flavonoids 25.37 g and total polyphenolic compounds 36.79 g (Fraisie et al. 2011). The highest amount of phenolic and flavonoid was detected in the methanol extract of chamomile aerial parts with a mean value of 50.7 and 36.7 % and the lowest in the aqueous extract with a mean value of 3.94 and 1.36 %, respectively (Haghi et al. 2013). The apigenin 7-glucoside (0.21–1.23 g/100 g dry samples) in the crude extracts was much higher than the free apigenin (0.04–0.74 g/100 g dry samples). The compounds detected were chlorogenic acid, caffeic acid, *p*-coumaric acid, salicylic acid and flavonoids, rutin, apigenin-7-glucoside, quercetin, luteolin, apigenin, kaempferol and isorhamnetin.

Matricaria chamomilla cell suspensions cultured in a two phase system consisting of an aqueous nutrient medium and a nontoxic lipophilic phase (triglyceride) accumulated (Bisson et al. 1983) a great number of lipophilic substances in the triglyceride phase during the first week of culture period. One of these substances was identified as α -bisabolol. The composition of the essential oil of chamomile hairy root cultures on different media, namely, Murashige-Skoog (MS) medium and Gamborg (B5) media, was found to be similar, but differing in proportion (Máday et al. 1999). The main component of the essential oil was *trans*- β -farnesene, as in the intact roots. Chamomile essential oil was found to contain primarily chamazulene, (–)- α -bisabolol, bisabolol oxides, bisabolol oxide A, *trans*- β -farnesene, α -farnesene, spathulenol, β -eudesmol and *cis/trans*-en-in-dicycloethers. Formaldehyde was found in intact plants, micropropagated plants and hairy root cultures of chamomile (Máday et al. 2000). HCHO should not be considered as a side product, but a basic and indispensable component, required for various biological processes in chamomile.

Flavonoids, Coumarins, Mucilages, Mono- and Oligosaccharides Also Had Pharmacological Effects

Among the cultivated and wild chamomile species examined, the wild species from the areas of Szeghalom were found to contain the highest quantity of β -eudesmol (9.25 % in the total essential oil) in intact and organized roots of chamomile cultures (Szöke et al. 2004a). A new component α -selinene (Szöke et al. 2004c) and germacrene D, berkeleyadulene, 4-(2', 4', 4'-trimethyl-bicyclo[4.1.0]hept-2'-en-3'-yl)-3-buten-2-one, geranyl-isovalerate and cedrol, were found in the hairy roots of sterile chamomile cultures (Szöke et al. 2004d). These cultures generated the most important terpenoid and polyin compounds characteristics of the intact plant. Among wild chamomile populations in Hungary, a population was found in the area of Szabadkigyós containing significant amounts, on average 48 %-of (-)- α -bisabolol in its inflorescence oil. The intact roots of in vitro cultures contained no (-)- α -bisabolol but contained the sesquiterpene alcohol β -eudesmol. The main components of hairy root cultures derived from wild chamomile rich in (-)- α -bisabolol in the inflorescence oil were *trans*- β -farnesene, α -farnesene, geranyl isovalerate and cedrol. β -Selinene was identified as a new component of the genetically transformed cultures (Szöke et al. 2004b).

Effect of Abiotic Factors on Chamomile Oil and Chemical Composition

Optimum chamomile oil yield was found to be strongly influenced by genotype and optimum ecological conditions (Bettray and Vömel 1992). Herb quantity, individual flower-head weight and days from buds to full-opened flowers of genotypes were reduced with increasing temperature, but content of apigenin, (-)- α -bisabolol and essential oil but not chamazulene rose with increasing temperature, optimal yields were obtained from 20 to 26 °C. The content of apigenin-7-glucoside was influenced by genotype and not temperature.

The increased content of the coumarin, umbelliferone, was observed in leaves 12 hours after abiotic stress elicitation by CuCl₂ (Repcák et al. 2001). In 48 hours, this amount rose approximately ten times. In the same period of time, a decrease of (Z)- and (E)-2- β -D-glucopyranosyloxy-4-methoxy cinnamic acid and an increase of herniarin were found. The content of herniarin in the CuCl₂-treated chamomile plants rose approximately three times, simultaneously with a decline of its precursor (Z)- and (E)-2- β -D-glucopyranosyloxy-4-methoxycinnamic acid (Eliasová et al. 2004). The highest amounts of umbelliferone in stressed plants exceeded 9 and 20 times those observed in control plants of the tetraploid and diploid cultivar, respectively. Due to stress, the concentration of ene-yne-dicycloether in leaves decreased by more than 40 %. The pattern of quantity changes of the examined compounds in tetraploid and diploid plants was similar. The aerial parts of chamomile were found to synthesize and accumulate (Z)- and (E)-2- β -D: -glucopyranosyloxy-4-methoxy cinnamic acids (GMCA), the precursors of phytoanticipin herniarin (7-methoxycoumarin), a compound with anticoagulant properties (Repcák et al. 2009).

Studies found that the yield of dry flower and essential oil per pot, essential oil percent and its composition in *Matricaria chamomilla* varied with irrigation regimes (Pirzad et al. 2006). Highest amount of essential oil percent, yield of dry flower and essential oil per pot were obtained from irrigation at 85 % of the field capacity. However, it was not significantly different from irrigation at 70 % of field capacity. Lowest amount of essential oil percent were obtained when the plants irrigated with 100 and 55 % of field capacity. Minimum yield of dry flower and essential oil per pot were observed when the plants irrigated with 55 % of field capacity, but it was not significantly different from irrigation at 100 % of field capacity. Major constituents of the essential oil for all irrigation treatments were azulene-7-ethyl-1,4-dimethyl, limonene, bisabolol oxides A and B, bisabolone oxide, *trans*- β -farnesene and isobornyl isobutyrate <8-isobutyryloxy>.

Nitrogen deficiency was found to induce changes of free amino acids and coumarin contents

in chamomile leaves (Kovacik et al. 2006). Among secondary metabolites, the sum of 2- β -D-glucopyranosyloxy-4-methoxycinnamic acids increased sharply, herniarin increased slowly and the content of umbelliferone was low in N-deficient plants. A decrease in levels of all detected amino acids, besides histidine, was found. Within aromatic amino acids, tyrosine was the most abundant. The content of free phenylalanine was significantly lower in both control and N-deficient plants when compared to the content of tyrosine. The increase of herniarin glucosidic precursors was attributed to enhancing phenylalanine ammonia-lyase activity under nitrogen deficiency and nitrogen-free carbon skeletons were shunted in to the phenylpropanoid metabolism, including biosynthesis of (Z)- and (E)-2- β -D-glucopyranosyloxy-4-methoxycinnamic acids.

In the 3 years' experiment (2005–2007), Gosztola et al. (2010) found the moderately warm and relatively wet year of 2006 produced the highest contents of essential oil and also that of its alpha-bisabolol component in 28 wild populations of chamomile and 4 registered cultivars. Although bisabolol oxide A also showed a high variability through the years, its direct connection with weather conditions could not be proven. A moderate variability was established for the proportions of chamazulene and the lowest one for bisabolol-oxide B. Considerable genotype–weather interaction was suggested, especially for the essential oil content and for the ratio of bisabolol oxide A. The results of studies suggested that the hexaconazole-induced tolerance to water deficit stress in chamomile was related to the changes in growth variables, antioxidants and the apigenin-7-glucoside content (Hojati et al. 2011). The exogenous application of 15 mg/l provided better protection when compared to the other concentration.

Chamomile had been reported to have antioxidant, antimicrobial antiplatelet activities in vitro and antiinflammatory, antimutagenic, cholesterol-lowering antispasmodic and anxiolytic activities in vivo (McKay and Blumberg 2006). However, human studies had been limited, and clinical trials examining the purported sedative properties of chamomile tea were lacking.

Antioxidant Activity

Chamomile flower essential oil exhibited good antioxidant when evaluated using the β -carotene bleaching assay (Owlia et al. 2007). Total antioxidant capacity (%) (DPPH scavenging activity) of chamomile aerial plant parts was 2.78 % and contribution from the main caffeoyl derivatives was as follows: chlorogenic acid 4.31 %, 3,5-DCQA (dicafeoylquinic acid) 13.66 %, 4,5-DCQA 7.53 % and total caffeoyl derivatives 25.50 % (Fraisie et al. 2011).

It was found that chamazulene, a bioactive compound of chamomile, inhibited lipid peroxidation in a concentration and time-dependent manner presenting an IC_{50} of 18 μ M after 45 minutes incubation (Rekka et al. 1996). It also inhibited the autoxidation of dimethyl sulfoxide (33 mM) by 76 % at 25 mM and had a weak capacity to interact with DPPH radical.

Anticancer Activity

Exposure of chamomile aqueous and methanolic extracts caused minimal growth inhibitory responses in normal cells, whereas a significant decrease in cell viability was observed in various human cancer cell lines (Srivastava and Gupta 2007, 2009). Chamomile exposure resulted in differential apoptosis in cancer cells but not in normal cells at similar doses. The aqueous and methanolic chamomile flower extracts exhibited antiproliferative and apoptosis inducing effects on human prostate cancer PC-3 cells (Srivastava and Gupta 2009). Exposure of PC-3 cells with aqueous chamomile extract for 24 hours resulted in dose-dependent increase in cell growth inhibition varying from 3 to 25 % at concentration ranging from 25 to 800 μ g/ml. Similarly, 4–74 % cell growth inhibition was observed after exposure of PC-3 cells to methanolic chamomile extract ranging from 25 to 800 μ g/ml. Exposure of PC-3 cells to both aqueous and methanolic chamomile extract at 200 μ g/ml concentration for 24 hours caused induction of apoptosis. Similar cell growth inhibitory and apoptotic effects were noted in other human cancer cell lines including breast, colon, fibrosarcoma and cervical

adenocarcinoma. Apigenin glucosides inhibited cancer cell growth but to a lesser extent than the parent aglycone, apigenin. Ex-vivo experiments suggested that deconjugation of glycosides occurred in vivo to produce aglycone, especially in the small intestine. The cytotoxicity of 10 essential oils including chamomile oil on human prostate carcinoma cell (PC-3) was significantly stronger than on human lung carcinoma (A549) and human breast cancer (MCF-7) cell lines (Zu et al. 2010). Studies showed the combination of 5-fluorouracil, an anticancer agent and bisabololoxide A, one of main constituents in German chamomile, inhibited the growth of human leukaemia K562 cells although the additive inhibition of growth by bisabololoxide A became smaller as the concentration of 5-fluorouracil increased (Ogata-Ikeda et al. 2011). The authors suggested that the simultaneous application of German chamomile containing bisabololoxide A may reduce the dose of 5-fluorouracil.

Studies demonstrated that chamomile and Marigold (*Calendula officinalis*) tea exerted selective dose-dependent cytotoxic action against target cancer cells; cytotoxicity of marigold tea was higher than chamomile (Matić et al. 2012). However, the cytotoxic effect of chamomile tea was very weak to healthy peripheral blood mononuclear cells (PBMC), while the effect of marigold tea on PBMC was more pronounced. Chemical analyses showed that dominant phenolic compounds in examined infusions and decoctions were flavonoid glycosides and hydroxycinnamic acid derivatives.

Antigenotoxic Activity

Three phenols (apigenin, bisabolol and protocatechuic acid) from two medicinal plants, *Matricaria chamomilla* and *Uncaria tomentosa*, showed an antigenotoxic effect against the hydrogen peroxide effect in the wing spot test of *Drosophila melanogaster* and also exhibited tumoricidal activity (Anter et al. 2011). Apigenin (2.24–35.96 mM) showed a lower 50 % inhibitory concentration than bisabolol and protocatechuic acid. They did not exhibit any genotoxic

effect. These phenolics also induced apoptosis in HL-60 leukaemia cells. The authors suggested that the antioxidant activity of *Chamomilla* and *Uncaria* could be partially responsible of their beneficial activity.

Antiinflammatory Activity

In Vitro Studies

Chamomile treatment inhibited LPS-induced NO production and significantly blocked interleukin IL-1 β , IL-6 and TNF α -induced NO levels in RAW 264.7 macrophages (Bhaskaran et al. 2010). Chamomile caused reduction in LPS-induced iNOS mRNA and protein expression. The study found that chamomile inhibited NO production and iNOS gene expression by inhibiting RelA/p65 activation and supported the utilization of chamomile as an effective antiinflammatory agent. Chamomile infusions from both the capitula and sifted flowers exhibited antiinflammatory activity when tested on phorbol 12-myristate 13-acetate-stimulated human adenocarcinoma gastric cells and human neutrophil elastase (Bulgari et al. 2012). This antiinflammatory activity was postulated due to the inhibition of neutrophil elastase and gastric metalloproteinase-9 activity and secretion, the inhibition occurring in a concentration-dependent manner. The promoter activity was also inhibited and the decrease of metalloproteinase-9 expression was found to be associated with the inhibition of NF- κ B driven transcription. The results suggested that the flavonoid-7-glycosides, major constituents of chamomile flowers, may be responsible for the antiinflammatory action of the chamomile infusion observed.

Studies showed that matricine, chamazulene, (–)- α -bisabolol and guaiazulene, components of chamomile exhibited varying degree of antiinflammatory activity in rat paw carrageenan oedema (Jakovlev et al. 1983). Two to four hours after administration, matricine on a molar basis was equally effective as (–)- α -bisabolol. In contrast, chamazulene and guaiazulene showed significantly less activity than (–)- α -bisabolol and matricine. After 4 hours, the pharmacological

effects of guaiazulene decreased significantly, whereas chamazulene showed nearly constant activities over the entire testing period. Safayhi et al. (1994) found that chamazulene inhibited the formation of leukotriene B₄ in intact neutrophilic granulocytes, while matricine showed no effect up to 200 μ M. Chamazulene (IC₅₀: 2 μ M), but not matricine, suppressed the chemical peroxidation of arachidonic acid. Further, matricine (up to 200 μ M) had no effects on the cyclooxygenase and 12-lipoxygenase activities in human platelets. Therefore, they concluded that chamazulene, but not matricine, may contribute to the antiinflammatory activity of chamomile extracts by inhibiting the leukotriene synthesis and additional antioxidative effects.

Matricine and chamazulene and (–)- α -bisabolol, components of chamomile essential oil, had no distinct effects on protamine sulphate-provoked degranulation of mast cells from Lewis-1a rats (Miller et al. 1996). The *trans*-enynedicycloether partly inhibited the degranulation of rat mast cells in concentrations above 10^{–4} M. Studies in lipopolysaccharide (LPS)-activated RAW 264.7 mouse macrophages suggested that modulation of inducible cyclooxygenase (COX-2) and inducible nitric oxide synthase (iNOS) by apigenin and related flavonoids (genistein, kaempferol) may be important in inflammation and carcinogenesis (Liang et al. 1999). Suppression of transcriptional activation of COX-2 and iNOS by apigenin might mainly be mediated through inhibition of I κ B kinase activity induced by LPS or interferon gamma. Chamazulene carboxylic acid, a natural profen and matricin, a degradation product of proazulenic sesquiterpene lactones, both found in chamomile and yarrow, were found to have antiinflammatory activity (Ramadan et al. 2006). Matricin and the yarrow proazulenes were proposed to be antiinflammatory through conversion to chamazulene carboxylic acid.

Aqueous herbal extracts of chamomile (*Matricaria chamomilla*), meadowsweet (*Filipendula ulmaria*) and willow bark (*Salix alba*) and isolated polyphenolic compounds (apigenin, quercetin and salicylic acid, 0–100 μ M) were found to have antiinflammatory activity in THP1 macrophages (Drummond et al. 2012). At concentrations

of 10 μ M, both apigenin and quercetin reduced interleukin IL-6 significantly. Apigenin at 10 μ M and quercetin at 25 μ M reduced tumour necrosis factor- α (TNF- α) significantly. Among the herbal extracts, willow bark had the greatest antiinflammatory activity at reducing IL-6 and TNF- α production. This was followed by meadowsweet and then chamomile.

Animal Studies

Alpha-bisabolol, a component of chamomile oil, suppressed carrageenan-induced paw oedema in rats (Jakolev and Schlichtegroll 1969). In mice, hydroalcoholic extracts of chamomile induced a reduction of oedema similar to the nonsteroidal antiinflammatory agent benzydamine used as reference (Tubaro et al. 1984). Three polysaccharides isolated from chamomile flower heads exhibited remarkable antiinflammatory activity against mouse ear oedema induced by croton oil (Füller et al. 1991, 1993, 2000). Animal studies showed that (–)- α -bisabolol, a bioactive sesquiterpene alcohol obtained from chamomile plant, was found to have peripheral antiinflammatory and antinociceptive activities (Rocha et al. 2011b). In the inflammatory models of paw oedema induced by carrageenan and dextran, the mice treated with (–)- α -bisabolol showed smaller oedemas compared to animals treated only with the vehicle. (–)- α -Bisabolol was capable of reducing paw oedemas induced by 5-HT but not oedemas induced by histamine. (–)- α -Bisabolol exhibited antinociceptive activity in the models of visceral nociception induced by acetic acid and in the second phase of the nociception test induced by the intraplantar administration of formalin. (–)- α -Bisabolol did not have any effect in a thermal nociception model using a hot plate but was able to reduce mechanical inflammatory hypernociception induced by carrageenan. These findings suggested the antinociceptive action of (–)- α -bisabolol was not linked to a central mechanism but instead was related to the inflammatory process. (–)- α -Bisabolol also decreased leukocyte migration, protein extravasations and the amount of TNF- α to the peritoneal cavity in response to carrageenan. Further, (–)- α -bisabolol diminished neutrophil degranulation in response to phorbol myristate acetate.

Clinical Studies

In a phase III double-blind, placebo-controlled study involving 164 patients (men and women), mouthwash containing chamomile flower extract did not decrease 5-fluorouracil-induced stomatitis (Fidler et al. 1996). Mazokopakis et al. (2005) reported a case of methotrexate-induced oral mucositis in a patient with rheumatoid arthritis, who was successfully treated with wild chamomile mouthwashes. Studies showed that hamsters with oral mucositis induced by 5-fluoracil treated with chamomile had a 12-fold greater chance of scoring zero (absence of mucositis) than the control group (Pavesi et al. 2011). Also animals treated with chamomile or the corticoid agent (betamethasone elixir—Celestone®) weighed significantly less than those in the control group. The group treated with the corticoid agent exhibited a more severe clinical condition, whereas the group treated with chamomile exhibited mild mucositis throughout the experiment. Analysis of the histopathological results demonstrated that the group treated with chamomile exhibited a lesser degree of mucositis throughout the evaluation period in comparison to the control and corticoid groups.

In a clinical dose response curve study of 25 patients with phlebitis, peripheral intravenous infusion of chamomile extract elicited an anti-inflammatory effect (Reis et al. 2011). The time regression of phlebitis was shorter for groups with 2.5 % concentration (mean=29.2 hours) and 5 % concentration (mean=38.8 hours). Local toxicity was almost not observed.

Wound Healing Activity

Studies showed that rats with dead space wounds from excision and incision, treated with chamomile, exhibited a greater reduction in the wound area when compared with the controls (61 % versus 48 %), faster epithelialization and a significantly higher wound-breaking strength after 15 days (Nayak et al. 2007). Additionally, wet and dry granulation tissue weight and hydroxyproline content were significantly higher. In separate studies, male albino rats with induced secondary degree cutaneous burns, treated by rubbing with chamomile extract dissolved in olive oil twice

a day, exhibited accelerated wound healing compared to control (Jarrahi 2008). In a subsequent study Jarrahi et al. (2010) demonstrated that chamomile extract dissolved in olive oil administered topically exhibited wound healing potential in linear incisional wound model in male Wistar rats. Studies by Martins et al. (2009) showed that male rats treated with chamomile presented significantly faster wound healing of experimental ulcers in comparison to those treated with corticosteroids, triamcinolone acetonide and clobetasol propionate. Other animal studies showed chamomile to have wound healing effect (Duarte et al. 2011). Rats with inflicted tongue ulcer treated with chamomile showed the best results regarding epithelialization and percentage of collagen fibers after 10 days. As expected, time had a statistically significant effect on fibroblast count, epithelialization, inflammation and wound size; animals sacrificed at 3 days showed the worst results.

In a double-blind trial of 14 patients with weeping wound area after dermabrasion of tattoos, the therapeutic efficacy of chamomile extract was shown by the significant decrease of the weeping wound area as well as the drying tendency (Glowania et al. 1987). In a controlled clinical study of colostomy patients with peristomal skin lesions, the lesions healed significantly faster in the chamomile than in the hydrocortisone group (Charousaei et al. 2011). Stoma patient symptoms (pain and itching) were also resolved more expediently in the chamomile than in the hydrocortisone group. The results suggested that German chamomile could be recommended to relieve itching and inflammation and that twice-daily application facilitated healing of peristomal skin lesions.

Antiviral Activity

Matricaria chamomilla was one of four plants found to inhibit the growth of human herpesvirus 1 and poliovirus 2 in cell culture (Suganda et al. 1983). The hydroalcoholic extract of *Matricaria chamomilla* was found to inhibit poliovirus cellular development and viral RNA synthesis

(Vilaginès et al. 1985). The essential oils anise oil, dwarf-pine oil and chamomile oil exhibited high levels of antiviral activity against acyclovir-sensitive herpes simplex virus type 1 (HSV-1) strain KOS and acyclovir-resistant clinical HSV isolates as well as acyclovir-resistant strain Angelotti (Koch et al. 2008a). At maximum non-cytotoxic concentrations of these plant oils, plaque formation was significantly reduced by 96.6–99.9 %, when herpes viruses were preincubated with drugs before attachment to host cells. No significant effect on viral infectivity could be achieved by adding these compounds during the replication phase. These results indicated that anise oil, dwarf-pine oil and chamomile oil affected the virus by interrupting adsorption of herpes viruses and in a different manner than acyclovir, which was effective after attachment inside the infected cells. Thus, the investigated essential oils were capable of exerting a direct effect on HSV and might be useful in the treatment of drug-resistant viruses. Additionally chamomile oil did not reveal any irritating potential on hen's egg chorioallantoic membrane, demonstrated the highest selectivity index among the oils tested and was highly active against clinically relevant acyclovir-resistant HSV-1 strains. They further found that chamomile oil exhibited a high selectivity index and appeared to be a promising candidate for topical therapeutic application as virucidal agents for treatment of herpes genitalis (Koch et al. 2008b). The inhibitory concentrations (IC₅₀) of chamomile oil against herpes simplex virus type 2 (HSV-2) in-vitro on RC-37 cells was 0.003 %. The results confirmed that essential oils like chamomile affected HSV-2 mainly before adsorption probably by interacting with the viral envelope.

Antimicrobial Activity

Of six matricaria esters (MEs) and two matricaria lactones (MLs), (2Z,8Z)-ME and (2E,8Z)-ME gave minimum inhibitory concentrations (MICs) of 50 µg/ml against *Mycobacterium tuberculosis* and respective MICs of 25 and 50 µg/ml against *Mycobacterium avium* (Lu et al. 1998). The

(4Z,8Z)-ML, (2Z)-8-dehydro-ME and (2Z,8Z)-10-angeloyloxy-(2Z,8Z)-ME showed respective MICs of 12.5, 25, 25 µg/ml against *M. tuberculosis* and MICs of 50, 25, 25 µg/ml against *M. avium*, respectively. The MICs of (2Z,8Z)-10-tigloyloxy-ME and (2E,8Z)-10-angeloyloxy-ME and (4E,8Z)-ML ranged from 50 to >100 µg/ml 1 against both pathogenic mycobacteria.

Chamomile flower essential oil was found to be strongly antimicrobial against *Streptococcus* pathogens in-vitro: *Streptococcus pyogenes*, *S. mutans*, *S. salivarius*, *S. faecalis* and *S. sanguis* with MICs/MBCs values (µg/ml) of 0.1/0.2, 0.5/1.5, 0.5/0.8, 4/7 and 0.5/11 respectively (Owlia et al. 2007). Chamomile essential oil was active against three strains of *Staphylococcus aureus*, *Candida albicans* and *Candida krusei* causal agents of acute otitis externa (Nogueira et al. 2008). Gram-positive bacteria were found to be more sensitive to the action of chamomile oil than Gram-negative bacteria (Aggag and Yousef 2009). The oil also showed marked fungicidal activity against *Candida albicans*. The incorporation of the volatile oil in topical preparations for staphylococcal infections was suggested. Chamomile flower oil exhibited antibacterial activity in-vitro against *Helicobacter pylori* (Shikov et al. 2008). The MIC₉₀ (minimal inhibitory concentration) and MIC₅₀ were 125 and 62.5 mg/ml, respectively. Chamomile oil extract inhibited the production of urease by *H. pylori* and affected the morphological and fermentative properties of *H. pylori*. Studies by Cwikla et al. (2010) found that the herbal extracts showing the highest growth inhibition of *Campylobacter jejuni* were *Calendula officinalis*, *Matricaria recutita*, *Zingiber officinale*, *Salvia officinalis*, *Foeniculum vulgare* and *Silybum marianum*. *C. jejuni* is the most common cause of enteric infections, particularly among children, resulting in severe diarrhoea.

German chamomile essential oil exhibited specific inhibition towards aflatoxin G(1) (AFG(1)) production, and (E)- and (Z)-spiroethers were isolated as the active compounds from the oil (Yoshinari et al. 2008). The (E)- and (Z)-spiroethers inhibited AFG(1) production of *Aspergillus parasiticus* with inhibitory concentration 50 %

(IC₅₀) values of 2.8 and 20.8 μ M, respectively, without inhibiting fungal growth. The spiroethers were found to inhibit *O*-methylsterigmatocystin conversion to AFG(1) pathway. The (*E*)- and (*Z*)-spiroethers inhibited the enzymatic activity of TRI4 dose-dependently and interfered with 3-ADON (trichothecene 3-acetyldeoxynivalenol) production by *Fusarium graminearum*, with IC₅₀ values of 27.1 and 103 μ M, respectively. Their results suggested that the spiroethers inhibited AFG(1) and 3-ADON production by inhibiting cytochrome CYP4 and TRI4, respectively.

Matricaria chamomilla extract and *Eugenia uniflora* were highly inhibitory against 16 *Staphylococcus aureus* strains (Silva et al. 2012). Studies showed that the antibacterial effect of 50 % aqueous ethanol extract of chamomile flower was attributable to *cis*-spiroether, *trans*-spiroether and the coumarins like herniarin and umbelliferone (Móricz et al. 2012).

In-vitro studies showed that *Aspergillus niger* growth was inhibited dose-dependently with a maximum of approximately 92.50 % at the highest chamomile flower essential oil concentration (Tolouee et al. 2010). A marked retardation in conidial production by the fungus was noticed in relation to the inhibition of hyphal growth. The main changes of hyphae observed by transmission electron microscopy were disruption of cytoplasmic membranes and intracellular organelles, detachment of plasma membrane from the cell wall, cytoplasm depletion and complete disorganization of hyphal compartments. The findings indicated the potential of chamomile essential oil in preventing fungal contamination and subsequent deterioration of stored food and other susceptible materials.

Antidiabetic Activity

In streptozotocin-induced diabetic rats, treatment with different doses of chamomile ethanol extract significantly reduced postprandial hyperglycaemia and oxidative stress, and augmented the antioxidant system (Cemek et al. 2008). In histological investigations, chamomile treatment protected the majority of the pancreatic islet cells, with respect

to the control group. As a result, chamomile exhibited significant antihyperglycemic effect and protected beta cells in streptozotocin-induced diabetic rats, in a dose-dependent manner, and diminished the hyperglycaemia-related oxidative stress. In another study, hot water chamomile extract and its major components esculetin (3) and quercetin (7) exhibited moderate inhibition of sucrase with IC₅₀ values of 0.9 mg/ml and 72 and 71 μ M, respectively (Kato et al. 2008). In a sucrose-loading test, the administration of esculetin (50 mg/kg body weight) fully suppressed hyperglycaemia after 15 and 30 minutes, but the extract (500 mg/kg body weight) and quercetin (50 mg/kg body weight) were less effective. In contrast, a long-term feed test (21 days) using a streptozotocin-induced rat diabetes model revealed that the same doses of chamomile extract and quercetin showed significant suppression of blood glucose levels. It was also found that these samples increased the liver glycogen levels. Further, chamomile extract exhibited potent inhibition against aldose reductase (ALR2), with an IC₅₀ value of 16.9 μ g/ml, and its components, umbelliferone (1), esculetin (3), luteolin (6) and quercetin (7), could significantly inhibit the accumulation of sorbitol in human erythrocytes. These results clearly suggested that daily consumption of chamomile tea with meals could contribute to the prevention of the progress of hyperglycaemia and diabetic complications. Chamomile extract exhibited antidiabetic potential in alloxan-induced diabetic rats (Estakhr and Javdan 2011). The extract significantly reduced the level of glucose, total cholesterol and triglycerides with an increase in insulin and glycogen concentration to near normal levels in a dose-dependent manner. In another study, administration of chamomile leaf extract 200 mg/kg body weight once daily for 21 days reduced the elevated fasted blood glucose (FBG) by 62.2 %, and the levels of urea, creatinine, uric acid, aspartate transaminase, alanine transaminase, alkaline phosphatase, total cholesterol, triglyceride and LDL-cholesterol were also reduced in streptozotocin-induced diabetic rats (Najla et al. 2012). There was also improvement in the histological changes in the liver. The results

demonstrated that the water extract of *Matricaria chamomilla* possessed a strong hypoglycemic effect in streptozotocin-induced diabetic rats.

Nephroprotective Activity

M. chamomilla injection of rats corrected the hypocalcaemia that resulted from cisplatin nephrotoxicity, normalized the kidney functions, improved the apoptotic markers, reduced the oxidative stress markers and significantly increased the body weight (Salama 2012). Its nephroprotective activity was probably attributed to its antioxidant activities and inhibition of gamma glutamyl transferase activity.

Neuroprotective Activity

Studies showed that the methanolic chamomile extract elicited potent dose-dependent neuroprotective activity against global cerebral ischaemia/reperfusion injury-induced oxidative stress in rats (Chandrashekhara et al. 2010). The extract decreased in lipid peroxidation and increase in the superoxide dismutase, catalase, glutathione and total thiol levels in extract treated groups as compared to ischaemia/reperfusion group. Cerebral infarction area was significantly reduced in extract treated groups as compared to ischaemia/reperfusion group. Another study showed that the methanol extract of German chamomile elicited potent neuroprotective activity against aluminium fluoride-induced oxidative stress in rats (Ranpariya et al. 2011). Chamomile significantly decreased lipid peroxidation and increased superoxide dismutase (SOD), catalase (CAT), glutathione (GSH) and total thiol levels in extract-treated animals as compared with negative control group. The histopathological studies also revealed the potent neuroprotective action of German chamomile against oxidative brain damage.

Immunomodulatory Activity

The heteroglycan polysaccharide was chamomile flower was found to enhance phagocytosis in

mice in the chemoluminescence model (Wagner et al. 1985). Maximum activity of 64 % was observed at a concentration of 10–3 mg/ml. Intragastric and parenteral administration of chamomile heteropolysaccharides chamomile was found to normalize the immune response upon air cooling and enhanced (but do not normalize) this process upon immersion cooling (Uteshev et al. 1999). The immunomodulating effect of the heteropolysaccharides upon cooling was attributed to initiation of immunostimulating properties of heavy erythrocytes (macrocytes), activation of immunoregulation cells of peripheral blood, and increased sensitivity of effector cells to helper signals.

Analgesic Activity

Administration of chamomile hydroalcoholic extract before formalin injection showed significant decrease of pain responses in vincristine-induced neuropathy in both phases in mice (Nouri and Abad 2012). Administration of vincristine produced significant increase in pain response in the second phase of the formalin test. Injection of chamomile and vincristine together showed that chamomile was able to decrease the vincristine induced pain significantly.

Anxiolytic/Antidepressant/Sedative Activities

Animal Studies

Lyophilized infusion of chamomile flower administered intraperitoneally in mice displayed a depressive effect on the central nervous system (Della Loggia et al. 1981, 1982). A sedative effect of chamomile flower extract was demonstrated via prolongation of hexobarbital-induced sleep, reduction of spontaneous mobility and reduction of explorative activity in mice. In contrast to diazepam, chrysin and apigenin do not cause reductions in memory. Restriction stress-induced increases in plasma ACTH (adrenocorticotrophic hormone) levels in normal and ovariectomized rats were decreased by inhalation of chamomile flower oil vapour and administration

of diazepam (Yamada et al. 1996). Inhaling chamomile vapour induced greater decreases in plasma ACTH levels in ovariectomized rats than treatment with diazepam; this difference was not observed in normal rats. The plasma ACTH level decreased further when diazepam was administered along with inhaling chamomile oil vapour. Flumazenil was found to block the decrease in plasma ACTH level induced by inhaled chamomile oil vapour.

Apigenin, from chamomile flower head, exhibited clear anxiolytic activity in mice in the elevated plus maze without evidencing sedation or muscle relaxant effects at doses similar to those used for classical benzodiazepines, and no anticonvulsant action was detected (Viola et al. 1995). Apigenin competitively inhibited the binding of flunitrazepam and had no effect on muscarinic receptors, alpha 1-adrenoceptors and on the binding of muscimol to GABA_A receptors. However, a tenfold increase in dosage produced a mild sedative effect since a 26 % reduction in ambulatory locomotor activity and a 35 % decrement in hole-board parameters were evident. The results indicated apigenin to be a ligand for the central benzodiazepine receptors exerting anxiolytic and slight sedative effects but not being anticonvulsant or myorelaxant. Electrophysiological studies performed on cultured cerebellar granule cells showed that apigenin, from methanol chamomile flower extract, reduced GABA (gamma-aminobutyric acid)-activated Cl⁻ currents in a dose-dependent fashion (Avallone et al. 2000). Apigenin reduced the latency in the onset of picrotoxin-induced convulsions. Further, apigenin injected i.p. in rats reduced locomotor activity, but did not demonstrate anxiolytic, myorelaxant or anticonvulsant activities. The results suggested that the inhibitory activity of apigenin on locomotor behaviour in rats could not be ascribed to an interaction with GABA(A)-benzodiazepine receptor but to other neurotransmission systems, since it was not blocked by Ro 15-1788. Of two flavonoids, apigenin and chrysin, contained in *Matricaria chamomilla*, chrysin exhibited a clear anxiolytic effect when injected at the dose of 1 mg/kg in rats, apigenin failed to exert this activity (Zanoli et al. 2000). The anxiolytic effect of

chrysin, which was blocked by the injection of Flumazenil, could be linked to an activation of the GABA(A) receptor unit.

Studies suggest that treatment with Chamomilla 6cH was found to be related to the recovery of basal behavioural conditions in mice subjected to stressful conditions (Pinto et al. 2008). Mice who cohabitated with a sick cagemate showed a decrease in their general activity, but those treated with Chamomilla 6cH were less severely affected. In the open field area model, only the amitriptyline and ethanol treated mice showed significant excitatory behaviour; chamomilla 6cH-treated animals scored intermediate between water control and ethanol or amitriptyline.

Studies found that *M. recutita* exhibited benzodiazepine-like effects of *Matricaria recutita* on morphine withdrawal syndrome in adult male Wistar rats (Kesmati et al. 2008). Chamomile decreased significantly the number of climbing in comparison to control group, but it had no significant effect on other signs. Flumazenil increased significantly the signs of jumping and face washing in comparison to control group. Chamomile in the presence of flumazenil exhibited no sedative effect and the climbing behaviour increased significantly. The sedative effect of *M. recutita* on morphine withdrawal syndrome was suggested to be related to its benzodiazepine-like components that acted on benzodiazepine receptors. Studies showed that pretreatment of male mice with different doses of chamomile hydro-methanolic extract increased the latency of the beginning time of seizure induced by picrotoxin (Heidari et al. 2009). The most effective dose was 200 mg/kg. In addition, this dose delayed the time of death in mice but had no effect on the death rate.

Matricaria recutita essential oil at 50 and 100 mg/kg significantly increased the numbers of spontaneous locomotor activities, exhibited anxiogenic effect in the open field, elevated plus-maze and social interaction tests and decreased the immobility times of mice in tail suspension tests (Can et al. 2012). The falling latencies in rotarod tests did not change. This activity profile of the essential oil was similar to the typical psychostimulant caffeine.

Clinical Studies

In a small observation study of three 14–16-year-old male psychiatric outpatients, diagnosed with attention-deficit disorder (ADHD), administration of chamomile was found to improve patients' mean score for Conners's hyperactivity, inattention and immaturity factors (Niederhofer 2009). The small study indicated that chamomile might be a slightly effective treatment also for ADHD.

In a randomized, double-blind, placebo-controlled efficacy trial involving 57 patients with mild to moderate generalized anxiety disorder (GAD) Amsterdam et al. (2009) observed a significantly greater reduction in mean total Hamilton Anxiety Rating (HAM-A) score during chamomile versus placebo therapy. They found that chamomile may have modest anxiolytic activity in patients with mild to moderate GAD. They conducted another randomized, double-blind, placebo-controlled study, to examine the antianxiety and antidepressant action of oral chamomile extract in participants with symptoms of comorbid anxiety and depression (Amsterdam et al. 2012). Of the 57 participants in the 2009 trial, 19 had anxiety with comorbid depression; 16 had anxiety with a past history of depression; and 22 had anxiety with no current or past depression. They observed a significantly greater reduction over time in total Hamilton Depression Rating (HAM-D) scores for chamomile versus placebo in all participants. They also observed a clinically meaningful but nonsignificant trend for a greater reduction in total HAM-D scores for chamomile versus placebo in participants with current comorbid depression. They found a significantly greater reduction over time for chamomile versus placebo in all participants in the HAM-D core mood item scores and a clinically meaningful but nonsignificant trend for a greater reduction over time for chamomile versus placebo in participants without current or past depression. Their findings suggested that chamomile may provide clinically meaningful antidepressant activity that occurs in addition to its previously observed anxiolytic activity. In a double-blind, randomized, placebo-controlled of subjects suffering generalized anxiety disorder, chamomile showed potential for use in treating such disorder (Faustino et al. 2010).

Inhibition of Morphine Dependence

Animal studies showed that the withdrawal behavioural manifestations and weight loss were inhibited significantly by chronic co-administration of *M. chamomilla* extract with morphine (Gomaa et al. 2003). Administration of a single dose of *M. chamomilla* before the naloxone challenge in morphine-dependent rats abolished the withdrawal behavioural manifestations. The dramatic increase of plasma cAMP induced by naloxone-precipitated abstinence was prevented by chronic co-administration of *M. chamomilla* extract with morphine. The results suggested that *M. chamomilla* extract inhibited the development of morphine dependence and expression of abstinence syndrome.

Sleep Enhancing Activity

A significant decrease in sleep latency in rats was observed with chamomile extract at a dose of 300 mg/kg, but no significant effects were observed on total times of wakefulness, non-rapid eye movement (non-REM) sleep, REM sleep and delta activity during non-REM sleep (Shinomiya et al. 2005). Chamomile extract was found to have benzodiazepine-like hypnotic activity.

In a randomized, double-blind, placebo-controlled pilot trial in 34 patients aged 18–65 years with DSM-IV (Diagnostic and Statistical Manual of Mental Disorders) primary insomnia for ≥ 6 -months, chamomile, 270 mg twice daily for 28 days, was found to provide modest benefits of daytime functioning and mixed benefits on sleep diary measures relative to placebo (Zick et al. 2011).

Oral Hygiene Activity

Chamomile hydroalcoholic extract was found to be significantly more effective than distilled water and tea tree oil (*Melaleuca alternifolia*) as an intracanal irrigant for the removal of the smear layer (Sadr Lahijani et al. 2006). The most effective removal of smear layer occurred with the use

of NaOCl with a final rinse of 17 % ethylenediaminetetraacetic acid (EDTA) (negative control) followed by the use of a chamomile extract. The use of a 2.5 % NaOCl solution alone, without EDTA and that of tea tree oil, was found to have only minor effects.

Gastroprotective/Antiulcerogenic Activities

Torrado et al. (1995) reported significant protective effect against gastric toxicity induced by 200 mg/kg acetylsalicylic acid was achieved after oral administration of chamomile oil to rats at doses ranging from 0.8 to 80 mg/kg (–)- α -bisabolol. Earlier, studies found that oral administration of chamomile flower extract and (–)- α -bisabolol inhibited the development of ulcers induced in rats by indomethacin, stress or ethanol (Szelenyi et al. 1979). They also reduced healing time for ulcers induced by chemical stress (acetic acid) or heat coagulation.

Extracts from the plants *Iberis amara*, *Melissa officinalis*, *Matricaria recutita*, *Carum carvi*, *Mentha x piperita*, *Glycyrrhiza glabra*, *Angelica archangelica*, *Silybum marianum* and *Chelidonium majus*, singly and combined in the form of a commercial preparation, STW 5 (Iberogast) and a modified formulation, STW 5-II, lacking the last 3 constituents, were found to have antiulcerogenic activity against indomethacin-induced gastric ulcers of rats (Khayyal et al. 2001). All extracts produced a dose-dependent antiulcerogenic activity associated with a reduced acid output and an increased mucin secretion, an increase in prostaglandin E2 release and a decrease in leukotrienes. The most beneficial effects were observed with the combined formulations STW 5 and STW 5-II in a dose of 10 ml/kg b.w., comparable with cimetidine in a dose of 100 mg/kg b.w. The antiulcerogenic activity of the extracts was also confirmed histologically. The cytoprotective effect of the extracts could be partly due to their flavonoid content and to their free radical scavenging properties.

Oral administration of chamomile extract at 400 mg/kg was found to be effective in preventing

HCl-ethanol-induced gastric ulceration in mice and did not produce toxic effects in doses up to 5,000 mg/kg (Karbalay-Doust and Noorafshan 2009). In another study, chamomile extract was found to reduce gastric damage in rats at all doses tested (Bezerra et al. 2009). α -bisabolol and its bioactive component at oral doses of 50 and 100 mg/kg markedly attenuated the gastric lesions induced by ethanol by 87 and 96 %, respectively. Further, the α -bisabolol effect was significantly reduced in rats pretreated with glibenclamide, an inhibitor of K^+ATP^- channel activation. The results suggested that α -bisabolol reduced the gastric damage induced by ethanol, at least in part, by the mechanism of activation of K^+ATP^- channels. In another study, oral administration of (–)- α -bisabolol (bioactive sesquiterpene from chamomile) 100 and 200 mg/kg was able to protect the gastric mucosa from ethanol (0.2 ml/animal p.o.) and indomethacin-induced ulcer (20 mg/kg p.o.) in mice (Moura Rocha et al. 2010). Administration of L-NAME (10 mg/kg i.p.), glibenclamide (10 mg/kg i.p.) or indomethacin (10 mg/kg p.o.) was not able to revert the gastroprotection promoted by (–)- α -bisabolol 200 mg/kg on the ethanol-induced ulcer. Dosage of gastric reduced glutathione (GSH) levels showed that ethanol and indomethacin reduced the content of nonprotein sulfhydryl (NP-SH) groups, while (–)- α -bisabolol significantly decreased the reduction of these levels on ulcer-induced mice, but not in mice without ulcer. The data indicated that the gastroprotective effect on ethanol and indomethacin-induced ulcer promoted by (–)- α -bisabolol may be associated with an increase of gastric sulfhydryl groups bioavailability leading to a reduction of gastric oxidative injury induced by ethanol and indomethacin. Using ethanol-induced gastric lesions model, Rocha et al. (2011a) found that (–)- α -bisabolol-induced gastroprotection was associated with reduction in oxidative stress caused by lipid peroxidation, increase in superoxide dismutase activity and reduction in inflammatory neutrophil migration in the gastric mucosa.

Pretreatment with chamomile hydroalcoholic extract significantly reduced ethanol-induced gastric lesions in rats (Cemek et al. 2010).

Chamomile significantly reduced malonaldehyde, and significantly increased GSH (reduced glutathione) levels in gastric tissue or whole blood. Serum beta-carotene and retinol levels were significantly higher in the 200 mg/kg chamomile-administered group with respect to control. The gastroprotective effect of chamomile was attributed, at least in part, upon the reduction in lipid peroxidation and augmentation in antioxidant activity. Studies showed that treatment with aqueous chamomile extract significantly and dose-dependently reduced gastric ulcer index induced by ethanol in albino rats (Al-Hashem 2010). Chamomile treatment prevented the fall in glutathione (GSH) level induced by ethanol and increased GSH level. Chamomile treatment alleviated, or completely resolved ethanol-induced degenerative alterations, including disorganization of cell nuclei and gland morphology with erosion in the gastric mucosa and interrupted muscularis mucosa.

Chamomile flowers have been traditionally used in the treatment of gastrointestinal disorders such as dyspepsia, gastritis and peptic ulcer disease. In a study of in-vitro susceptibility of 15 *Helicobacter pylori* strains to botanical extracts, Mahady et al. (2005) found that the methanol extracts of *Myristica fragrans* (seed) had a MIC of 12.5 µg/ml; *Zingiber officinale* (ginger rhizome/root) and *Rosmarinus officinalis* (rosemary leaf) had an MIC of 25 µg/ml. In comparison methanol extracts of *Matricaria recutita* (flowers) and *Ginkgo biloba* (leaves) were less potent with a MIC >100 µg/ml.

In double-blind, randomized, placebo-controlled, multicenter trial of 120 patients with functional dyspepsia, the herbal preparation (bitter candy tuft, matricaria flower, peppermint leaves, caraway, licorice root and lemon balm) tested improved dyspeptic symptoms significantly better than placebo after 8 weeks treatment (Madisch et al. 2004).

Hepatoprotective Activity

The methanol extract of chamomile capitula (300 mg/kg) exhibited significant antioxidant activity against CCl₄ induced liver injury in rats

(Gupta et al. 2006). The extract exhibited significant antioxidant activity by showing increased levels of glutathione peroxidase, glutathione-S-transferase, glutathione reductase, superoxide dismutase, catalase and glutathione. It decreased lipid peroxidation and halted hepatic damage. The aqueous ethanolic extract of chamomile capitula exhibited hepatoprotective activity against paracetamol-induced hepatic damage in albino rats (Gupta and Misra 2006). Chamomile extract protected against decreases in the levels of GSH, blood glutathione, serum marker enzymes, liver Na⁺K⁺-ATPase activity, abnormal high level of serum alanine transaminase (ALT), aspartate transaminase (AST) and alkaline phosphatase (ALP) bilirubin and increased liver thiobarbituric acid-reactive substance resulting from hepatocellular damage and hepatic dysfunction induced by paracetamol.

Antipruritic/Antiallergic Activity

In a study 161 patients suffering from inflammatory dermatoses on hands, forearms and lower legs, 3–4 weeks application of Kamillosan cream (containing chamomile extracts) was found to be as effective as hydrocortisone for eczema and more effective than 0.75 % fluocortin butyl ester and 5 % bufexamac (Aertgeerts et al. 1985). A controlled and physician-blind randomized trial found no major differences in skin reactions after acute radiation between areas treated with Kamillosan cream (chamomile) and almond ointment (Maiche et al. 1991). None of these agents could prevent the skin reaction and all patients got grade 1 erythema. A lesser number and a later appearance of grade 2 reactions suggested an advantage for Kamillosan cream, although the difference between the results achieved was not statistically significant. The patients, however, preferred Kamillosan cream because of its rapid absorption and stainlessness. In a partially double-blind, randomized study carried out as a half-side comparison, 2 weeks application of Kamillosan(R) cream showed a mild superiority towards 0.5 % hydrocortisone and a marginal difference as compared to placebo in atopic eczema (Patzelt-Wenzler and Ponce-Pöschl 2000).

Intradermal application of liposomal apigenin-7-glucoside inhibited in a dose-dependent manner skin inflammation caused by xanthine oxidase and cumene hydroperoxide in rats (Fuchs and Milbradt 1993). Glucose-oxidase (hydrogen peroxide)-induced dermatitis was not significantly inhibited. The results are in good agreement with the in-vitro superoxide anion radical and peroxyl radical scavenging properties of apigenin and indicated that its antioxidant properties may have contributed to the antiinflammatory effect in this model system. The ethyl acetate extract of German chamomile dose-dependently suppressed compound 48/80-induced scratching without affecting body weight increase in ddY mice (Kobayashi et al. 2003). The ethyl acetate fraction of the ethanol extract and the ethanol extract of hot water extraction residue of German chamomile flower also showed strong inhibition on the compound 48/80-induced scratching. The inhibitory effects of the dietary intake of the German chamomile extracts on compound 48/80-induced itch-scratch response were comparable to oxatamide (10 mg/kg, p.o.), an antiallergic agent. The combined administration of the ethyl acetate extract of German chamomile (300 mg/kg) and antihistamine H1 antagonists, oxatamide (10 mg/kg) and fexofenadine (10 mg/kg), remarkably enhanced the antipruritic effects of these agents mice (Kobayashi et al. 2005). They found that the co-medication with the ethyl acetate extract or essential oil of German chamomile and antihistamines might be effective for the pruritus which could not be perfectly resolved alone by conventional antihistamines.

The methanol chamomile extract exhibited inhibitory effects on anaphylaxis induced by compound 48/80 and significant dose-dependent antipruritic property by inhibiting mast cell degranulation in rats (Chandrashekar et al. 2011). Dose-dependent reduction in the histamine release, along with decreased release of serum, rat peritoneal and bronchoalveolar lavage fluid nitric oxide (NO) levels was observed. The results suggested the methanol chamomile extract exhibited potent antiallergic activity by inhibition of histamine release from mast cells.

Spasmolytic Activity

Alcoholic chamomile extracts obtained from ligulate flowers appeared to exert stronger spasmolytic activity than from tubular florets (Achterrath-Tuckermann et al. 1980; Carle and Gomaa 1992). Beside flavonoids, components of the essential oil were assumed to contribute to the spasmolytic effects. (–)- α -bisabolol, (+)- α -bisabolol and, to a lower extent their oxides, the chamomile oil itself, *cis*-spiroether, a standardized hydroalcoholic extract (Kamillosan®) and the coumarin derivatives umbelliferone and herniarin, exhibited spasmolytic activity in isolated guinea pig ileum. The hydrophilic (flavonoids) and the lipophilic components (essential oil) of chamomile were found to contribute to the musculotropic antispasmodic effect.

The extract of dried chamomile flowers was found to contain a potent tachykinin the extract of dried. The structure of the antagonist was identified as N1,N5,N10,N14-tetrakis[3-(4-hydroxyphenyl)-2-propenoyl]-1,5,10,14-tetraazatetradecane (tetracoumaroyl spermine, 1a) (Yamamoto et al. 2002). The K_i values of 1a, estimated from the inhibitory action on the substance P (SP)-induced contraction of the guinea pig ileum and the inhibition of the binding of [3H][Sar9, Met(O2)11] SP to human NK1 receptors, were 21.9 and 3.3 nM, respectively. The antagonist was concentrated in chamomile pollen. Another new compound found in the flower, N1,N5,N10-tris[3-(4-hydroxyphenyl)-2-propenoyl]-1,5,10,14-tetraazatetradecane, exhibited no tachykinin antagonist activity.

Inhibition of human cAMP-phosphodiesterase was found to be a mechanism for the spasmolytic effect of *Matricaria recutita* (Maschi et al. 2008). Chamomile flower/capitula infusion inhibited human platelet cAMP- and cGMP-phosphodiesterases (PDE) activity (IC_{50} = 17.9–40.5 μ g/ml), while cGMP-PDE5 was less affected (–15 % at 50 μ g/ml). Among the individual compounds tested, only flavonoids showed an inhibitory effect (IC_{50} = 1.3–14.9 μ M), contributing to around 39 % of the infusion inhibition; other compounds responsible for cAMP-PDE inhibition still remain unknown.

Antidiarrhoeal Activity

The results obtained in the study by Calzada et al. (2010) provided some scientific support to the popular use of 23 of the plants including *M. recutita*, tested for the treatment of gastrointestinal disorders such as diarrhoea in Mexican traditional medicine. These plants showed moderate inhibitory activity (30–100 %) against charcoal-gum acacia-induced hyperperistalsis in rats. Their activities were greater than that of or equal to loperamide (34 % of inhibition at doses of 10 mg/kg) drug used as control.

Antimutagenic Activity

Studies found chamomile essential oil exhibited a dose-dependent inhibitory effect on the sister chromatid exchanges formed by both mutagens, daunorubicin and methyl methanesulfonate (Hernández-Ceruelos et al. 2002). In the case of daunorubicin, a statistically significant result was observed in the three tested doses: from the lowest to the highest dose, the inhibitory values corresponded to 25.7, 63.1 and 75.5 %. No alterations were found with respect to the cellular proliferation kinetics, but a reduction in the mitotic index was detected. In the case of methanesulfonate, the inhibitory values were 24.8, 45.8 and 60.6 %; no alterations were found in either the cellular proliferation kinetics or in the mitotic indices. Their results suggested chamomile oil may be an effective antimutagen. Alpha-bisabolol (BISA), a sesquiterpene alcohol found in chamomile oil, markedly and dose-dependently reduced the mutagenic effects of aflatoxin B1, 2-aminoanthracene and 2-aminofluorene, cyclophosphamide and benzo[a]pyrene, B[a]P mutagens using TA100, TA98, TA97a and TA1535 *Salmonella typhimurium* strains, without and with addition of S9 mixture microsome assay (Gomes-Carneiro et al. 2005). Gomes-Carneiro showed weak inhibitory effect on 4-nitroquinoline-*N*-oxide and 2-nitrofluorene and did not alter the mutagenicity of sodium azide and 4-nitroquinoline-*N*-oxide mutagens. It was also found that BISA inhibited pentoxyresorufin-*o*-deethylase and

ethoxyresorufin-*o*-deethylase, markers for cytochromes CYP2B1 and 1A1 in rat liver microsomes. The results suggested that BISA-induced antimutagenicity could be mediated by an inhibitory effect on the metabolic activation of these promutagens.

Antiarthritic Activity

In a placebo-controlled double-blind crossover trial of 42 patients (40–76 years old) with painful knee osteoarthritis, administration of the herbal pomade Marhame-Mafasel (comprising a mixture of medicinal herbs including *Arnebia euchroma* and *Matricaria chamomilla*) elicited positive analgesic (pain reduction) effect in primary knee osteoarthritis (Soltanian et al. 2010). The herbal joint pomade Marhame-Mafasel had a significantly greater mean change in score compared to the placebo group for osteoarthritis severity.

Cardiovascular Activity

Haemodynamic measurements were obtained prior to and 30 minutes after the oral ingestion of chamomile tea on 12 patients with cardiac disease who underwent cardiac catheterization (Gould et al. 1973). With chamomile tea, the patients demonstrated a small but significant increase in the mean brachial artery pressure. No other significant haemodynamic changes were observed.

All the test beverages containing different polyphenol structures and being rich in either phenolic acids (chlorogenic acid in coffee), monomeric flavonoids (herb teas), chamomile (*Matricaria recutita*), vervain (*Verbena officinalis*), lime flower (*Tilia cordata*), pennyroyal (*Mentha pulegium*) and peppermint (*Mentha piperita*) or complex polyphenol polymerization products (black tea and cocoa) were found to be potent inhibitors of Fe absorption and reduced absorption in a dose-dependent fashion depending on the content of total polyphenols (Hurrell et al. 1999). Compared with a water control meal, beverages containing 20–50 mg total polyphenols/serving

reduced Fe absorption from the bread meal by 50–70 %, whereas beverages containing 100–400 mg total polyphenols/serving reduced Fe absorption by 60–90 %. Inhibition by black tea was 79–94 %, peppermint tea 84 %, pennyroyal 73 %, cocoa 71 %, vervain 59 %, lime flower 52 % and chamomile 47 %. At an identical concentration of total polyphenols, black tea was more inhibitory than cocoa, and more inhibitory than herb teas chamomile, vervain, lime flower and pennyroyal, but was of equal inhibition to peppermint tea.

Menopause Treatment Activity

In a placebo-controlled experiment on 55 postmenopausal women who complained of hot flushes and refused hormonal therapy, 12-week treatment with Climex (*Angelica sinensis* and *Matricaria chamomilla* plant extracts) appeared to be effective for menopausal symptoms without apparent major adverse effects (Kupfersztain et al. 2003). This hormone-free preparation may be used as an important modality for menopausal women with contraindications for hormone replacement therapy.

Antiosteoporotic Activity

Studies demonstrated that all the plant extracts (*Sideritis euboea*, *Sideritis clandestina*, *Matricaria chamomilla* and *Pimpinella anisum*) studied at a concentration range 10–100 µg/ml stimulated osteoblastic cell differentiation and exhibited antiestrogenic effect on breast cancer cells without proliferative effects on cervical adenocarcinoma (HeLa) cells (Kassi et al. 2004). The presence of estradiol inhibited the antiestrogenic effect induced by the extracts on MCF-7 breast cancer cells, suggesting an estrogen receptor-related mechanism. The authors concluded that the aqueous extracts derived from *Sideritis euboea*, *Sideritis clandestina*, *Matricaria chamomilla* and *Pimpinella anisum* may form the basis to design ‘functional foods’ for the prevention of osteoporosis.

Antifertility Activity

Chamomile hydroalcoholic extract was found to decrease spermatozoa count and motility, spermatozoon tail length and serum testosterone level and increase serum estradiol level in male adult rat (Karbalay-Doust et al. 2010). The body weight and weight and volume of the testis in the control and treated rats did not change significantly.

Antileishmanial Activity

Chamomile essential oil was found to be active against *Leishmania infantum* promastigotes, the main species responsible for human leishmaniasis in Spain (Morales-Yuste et al. 2010). At the two highest concentrations tested (1,000 and 500 µg/ml), (–)α-bisabolol (a principal chamomile oil component) and pentamidine (control agent) achieved 100 % inhibition of *L. infantum* promastigote. 80 % ethanol chamomile extract inhibited *Leishmania mexicana* growth by 100 % at protein concentration of 0.8 mg/ml (Shnitzler et al. 1996). Chamomile also inhibited human cell lines HeLa growth by 78 % and T₄ growth 100 %.

Anthelmintic Activity

Studies found *Matricaria chamomilla* essential oil and two of its main components (chamazulene and α-bisabolol) to have larvicidal activity against the L(3) larvae of the nematode *Anisakis* type I in in vitro and in vivo assays (Romero et al. 2012). The essential oil (125 µg/ml) caused the death of all nematodes, which showed cuticle changes and intestinal wall rupture. In the in-vivo assays, only 2.2 % of infected rats treated with the essential oil showed gastric wall lesions in comparison to 93.3 % of control. Chamazulene was ineffective, while α-bisabolol showed high activity to that of the essential oil in in vitro tests but proved less active in vivo. These findings suggested that the larvicidal activity may result from the synergistic action of different compounds of

M. chamomilla essential oil. Neither of the tested products induced irritative damage in the intestinal tissues.

Herb/Drug Interaction Activity

The crude chamomile essential oil demonstrated inhibition of four selected human cytochrome P450 enzymes (CYP1A2, CYP2C9, CYP2D6 and CYP3A4), with CYP1A2 being more sensitive than the other isoforms (Ganzera et al. 2006). Three constituents of the oil, namely, chamazulene ($IC_{50}=4.41\text{ }\mu\text{M}$), *cis*-spiroether ($IC_{50}=2\text{ }\mu\text{M}$) and *trans*-spiroether ($IC_{50}=0.47\text{ }\mu\text{M}$), showed to be potent inhibitors of this enzyme, also being active towards CYP3A4. CYP2C9 and CYP2D6 were less inhibited; only chamazulene ($IC_{50}=1.06\text{ }\mu\text{M}$) and α -bisabolol ($IC_{50}=2.18\text{ }\mu\text{M}$) revealed a significant inhibition of the latter. These in-vitro data suggested that chamomile preparations containing constituents that inhibited the activities of major human drug metabolizing enzymes may interact with drugs whose route of elimination is mainly via cytochromes (especially CYP1A2). Segal and Pilote (2006) reported a case of a 70-year-old woman who, while being treated with warfarin, was admitted to hospital with multiple internal haemorrhages after having used chamomile products (tea and body lotion) to soothe upper respiratory tract symptoms. This case highlighted a theoretical risk for potentiation, since chamomile contained coumarins.

Inhibition of Mycotoxin Production

Precocenes and piperitone isolated from chamomile essential oil inhibited deoxynivalenol production by *Fusarium graminearum* and may be useful for protecting crops from deoxynivalenol contamination (Yaguchi et al. 2006). Precocenes I and II and piperitone inhibited the production of 3-acetyldeoxynivalenol, a biosynthetic precursor of deoxynivalenol produced by *F. graminearum* in a liquid and solid cultures. Precocene II and piperitone decreased the mRNA levels of *Tri4*,

Tri5, *Tri6* and *Tri10* encoding proteins required for deoxynivalenol biosynthesis. The (*E*)-spiroether and (*Z*)-spiroether isolated from chamomile essential oil showed specific inhibition towards aflatoxin G(1)(AFG(1)) production by the fungus *Aspergillus parasiticus* without inhibiting fungal growth (Yoshinari et al. 2008). (*E*)- and (*Z*)-spiroethers inhibited the enzymatic activity of TRI4 dose-dependently and interfered with 3-acetyldeoxynivalenol production by *Fusarium graminearum*.

Insecticidal Activity

Treatment with the volatile oils of chamomile flowers ($LD_{50}\text{ }76\text{ }\mu\text{g/fly}$) and *Clerodendron inermis* leaf ($LD_{50}\text{ }64\text{ }\mu\text{g/fly}$) induced serious effects on the biology and biotic potential of the adult house fly *Musca domestica* (Shoukry 1997). Treatment significantly increased the acidic and the aromatic amino acids during oogenesis and significantly decreased content of aliphatic amino acids. The concentration of basic and the sulphur amino acids was varied with the two treatments, and the amino acid was completely disappeared in the ovaries of the treated flies.

Pharmacokinetic Studies

After oral ingestion of 40 ml of a hydroethanolic chamomile flower extract (containing 225.5 mg of apigenin 7-glucoside, 22.5 mg of apigenin and 15.1 mg of herniarin per 100 ml), no flavones could be detected in blood plasma nor in 24-hours urine of the female volunteer, while herniarin was found in both (maximum plasma concentration of 35 ng/ml; 0.324 mg in 24-hours-urine) (Tschirsch and Hölzl 1993).

Allergy Problem

Subiza et al. (1990) reported seven hay fever patients that suffered from conjunctivitis, two of them also had lid angioedema after eye washing with chamomile tea. All seven patients had positive

skin prick tests to the chamomile tea extract, *Matricaria chamomilla* pollen and *Artemisia vulgaris* pollen extracts. Positive conjunctival provocations were also observed in all the patients with the chamomile tea extract. They found that chamomile tea eye washing could induce allergic conjunctivitis and attributed this to pollens contained in these infusions as the allergens responsible for these reactions. German chamomile, a common and well-known allergen, had been reported to elicit type-IV allergic reactions such as allergic and systemic contact dermatitis in some people consuming chamomile tea (Pereira et al. 1997; Rodríguez-Serna et al. 1998).

In a clinical study conducted between 1991 and 2009, 36 selected patients with known or suspected Compositae contact allergy were patch tested with herniarin (from chamomile) 1 % petrolatum (Paulsen et al. 2010). Among 36 patients tested, there was 1 positive and 3 doubtful positive reactions to herniarin. All 4 patients had a relevant contact allergy to German chamomile, whereas the majority of the remaining 32 patients had chamomile allergy of unknown relevance. Sensitization may occur through, for example, external use of chamomile tea or use of chamomile-containing topical herbal remedies. Andres et al. (2009) reported a case of a 38-year-old Caucasian man who developed an episode of severe anaphylaxis with generalized urticaria, angioedema and severe dyspnoea 1 hour after consuming chamomile tea. Laboratory examination demonstrated a total serum IgE of 123 kU/l with specific IgE against chamomile (4.94 kU/l, class 3). Skin prick test and labial provocation test with chamomile elicited a strong positive reaction. Their case confirmed the presence of a type-I allergy to orally ingested chamomile. Contact dermatitis from bisabolol, a primary component in German chamomile, had been reported in Europe and in the United States (Russell and Jacob 2010). Patch testing with bisabolol-containing products or bisabolol may be useful in the work-up of patients with presumptive allergic contact dermatitis or potentially worsening atopic dermatitis. Patients sensitized to bisabolol should be counselled to avoid any bisabolol-containing products.

Toxicity/Safety Studies

Bisabololoxide A (BSBO), a principal constituent in German chamomile, was found to induce apoptosis and cellular changes of rat thymocytes when incubated with BSBO at concentrations of 30 μ M for 24 hours (Ogata et al. 2010). The significant changes in cellular parameters of rat thymocytes by BSBO were not observed when the concentration was 10 μ M or less. Furthermore, the short incubation (3 hours) of cells even with 30–100 μ M BSBO did not significantly affect the cells. Therefore, the authors suggested BSBO to be practically safe when German chamomile is conventionally used.

Traditional Medicinal Uses

Chamomile has been used as herbal folk medicine since antiquity in ancient Egypt, Greece and Rome (Mann and Staba 1986). The herb is considered antispasmodic, carminative, diaphoretic, sedative, stomachic and emmenagogue (Grieve 1971; Mann and Staba 1986; Martens 1995; Alberts 2009). The herb has been used as bitter, tonic, insect repellent, antiseptic, antispasmodic, sudorific and anthelmintic and as a folk remedies against asthma, colic, fevers, inflammations and cancer. It is used as a digestive aid to treat gastrointestinal disturbances including flatulence, motion sickness, indigestion, nausea and vomiting and as a liver stimulant (Mann and Staba 1986). It is used to treat hysteria, nightmares and other sleep problems (Martens 1995). Eye washing with chamomile tea is a folk remedy used by the general public to treat conjunctivitis and other ocular reactions (Subiza et al. 1990). Chamomile has long been used in traditional medicine for the treatment of inflammation-related disorders (Bhaskaran et al. 2010). In a 3-year study of ethnopharmacology and folk-medicine use among the population of the Atlantic Coast of Colombia, 39 plant species were identified to be of traditional medical importance, among which was *M. chamomilla* for colic ailments (Gómez-Estrada et al. 2011).

Other Uses

Chamomile (dried flower heads and extracts) is used in medicine, tinting hair and in cosmetics. Dried chamomile leaves are used in potpourri and herb pillows for their aromatic apple-like smell. The leaves are burnt in aromatherapy for their soothing scent to relax the mind and body. In Egypt, chamomile is steep in religion as the plant was consecrated to the god of the sun.

Chamomile flowers also have insecticidal properties. Studies showed that chamomile flower-head extracts elicited highly significant acaricidal activity against the mite *Psoroptes cuniculi*, responsible for otoacariasis in domestic animals (Macchioni et al. 2004). The decoction of 10 % was the only formulation which gave 100 % activity at all the three observations times of 24, 48 or 72 hours. Chamomile flower extract was found to have acaricidal activity against engorged *Rhipicephalus annulatus* tick in-vitro (Pirali-Kheirabadi and Razzaghi-Abyaneh 2007). The mortality rate caused by different dilutions of chamomile flower extract ranged from 6.67 to 26.7 %, whereas no mortality was recorded for non-treated control group. The mass of produced eggs varied from 0.23 g (in 8.0 % solutions) to 0.58 g (in control), with no statistical differences between the treatments and control. In the highest concentration used (8.0 %) chamomile extract caused 46.67 % failure in egg laying in engorged females while non-failure was observed for non-treated control group. Macroscopic observations indicated that in effective concentrations of the extract (4.0 and 8.0 %), patchy haemorrhagic swelling appeared on the skin of treated ticks.

Comments

Chamomile is cultivated commercially in Europe, Belarus, Ukraine, Moldova, North Caucasus to South Siberia, North Africa (Egypt, Ethiopia), Middle Asia (Turkey, Afghanistan), Asia (Pakistan, North India and Japan), North and South America (Eastern USA, Cuba, Argentina and Brazil), and New Zealand (Alberts 2009).

Tagetes erecta

Scientific Name

Tagetes erecta L.

Synonyms

Tagetes ernstii H. Rob. & Nicolson, *Tagetes excelsa* Soule, *Tagetes heterocarpa* Rydb., *Tagetes major* Gaertn. (illeg.), *Tagetes remotiflora* Kunze, *Tagetes tenuifolia* Millsp.

Family

Asteraceae

Common/English Names

African Marigold, American Marigold, Aztec Marigold, Big Marigold, Marigold, Mexican Marigold, Saffron Marigold

Vernacular Names

Chinese: Wan Shou Ju, Wan Shou Ju Ye

Czech: Aksamitník Vzpřímený

Danish: Opret Fløjlsblomst

Dutch: Afrikaantje

Eastonian: Kõrge Peulill

Esperanto: Tageto, Taĝeto

Finnish: Isosamettikukka

French: Rose D'inde, Tagète Rose D'inde

German: Hohe Studentenblume, Studentenblume

Swahili: Tururu

Swedish: Stor Tagetes

Thai: Dao Ruang

Origin/Distribution

Tagetes erecta is native to Central America—Mexico and Guatemala—and most probably naturalized in the rest of Central America and the western Andes of South America. In Mexico, it is found in the wild in the states of San Luis Potosí, Chiapas, State of México, Puebla, Sinaloa, Tlaxcala and Veracruz. It became naturalized also elsewhere in the tropics and subtropics and is widely cultivated globally as a popular garden ornamental. It is cultivated commercially for its dye mainly in Latin America, in Africa on a small scale in Zambia and South Africa.

Agroecology

Tagetes erecta is found wild in the pine–oak forest zone of Mexico in a warm, low-humidity climate. In the tropics, it grows well up to 2,000 m altitude as in the Andes. It thrives best in sunny locations, in well-drained loamy and clay soils of varying pH. Besides being grown as a garden ornamental, it is often found as an escape, e.g. in the United States, where it occurs along roadsides.

Edible Plant Parts and Uses

The flowers are eaten in Thailand (Kaisoon et al. 2011, 2012). *T. erecta* is grown commercially for the extraction of a food colourant (Tanaka 1976; Facciola 1990; Green 1995). The food colourant lutein is a purified extract obtained from marigold oleoresin, which is extracted from the petals of marigold flowers with organic solvents (Cantrill 2004). The food colourant is used in baked goods and baking mixes (cereal and energy bars, crackers and crispbreads), beverages and beverage bases (bottled water, carbonated beverages, meal replacements and ready-to-drink tea), breakfast cereals (instant and regular hot cereals), chewing gum, dairy product analogues (imitation milks, soy milk), egg products (liquid, frozen or

dried egg substitutes), fats and oils (margarine-like spreads, butter, cheese, salad dressings), frozen dairy desserts and mixes (frozen yogurt), gravies and sauces (tomato-based sauces), hard candy, infant and toddler foods (junior-, strained- and toddler-type baby foods), milk products (dry milk, fermented milk beverages, flavoured milk and milk drinks, milk-based meal replacements, yogurt), processed fruits and fruit juices (energy, sport and isotonic drinks; fruit juices; nectars; vegetable juice), soft candy (chewy and nougat candy), fruit snacks, and soups and soup mixes (canned soups) (Green 1995; Cantrill 2004).

Marigold (*Tagetes erecta*) inflorescences have been utilized as lutein pigment source for food colouring, mainly of poultry skin and eggs (Del Villar-Martínez et al. 2010). Marigold flowers are also a good source of carotenoids. There are many reports on carotenoids and their effect on the prevention of certain ocular diseases, ischaemic heart disease, strokes, photoprotection, immune response, aging and cancer.

Botany

An erect branched, coarse, glabrous herbaceous annual herb 3–180 cm tall with angular to rounded stems and a tap root. Leaves deeply pinnatifid with 6–17 linear-lanceolate segments, each segment 1–4 cm×0.5–2 cm, glandular, acute at both ends and margin serrate (Plates 1 and 2). Inflorescence a solitary terminal capitulum, (3–)5–12 cm across; peduncle 3–12 cm long. Involucre campanulate with 4–10 acute or obtuse lobes each bearing 2 rows of linear glands. Ray florets, female, ligulate, broadly obovate, 5–9 in 1-seriate in wild types, numerous in cultivars, yellow in wild types, lemon-yellow, orange to deep brown-red in cultivars (Plates 1 and 2). Disc florets, tubular, numerous, 8–10 mm long; stamens 5, anthers united into a tube around the style; ovary inferior, 1-loculed, style bifid. Fruit an angular achene 7–10 mm long, black, glabrous to finely hispid, with pappus of basally connate scales.

Nutritive/Medicinal Properties

Flower Phytochemicals

Marigold flower (*Tagetes erecta*) is one of the richest and purest sources of xanthophylls (Tsao et al. 2004; Sowbhagya et al. 2013). The main carotenoid found in *Tagetes erecta* petals was *trans* lutein ($C_{40}H_{56}O_2$), occurring in either free or esterified to one or two fatty acids (Gómez et al. 1978). About 95 % of lutein present in the flowers was reported to be in the form of esters out of with lutein palmitate as the major pigment (Gau et al. 1983). Dimyristate, myristate, palmitate, stearate and distearate were the other esters of lutein present in marigold flowers. Lutein ester concentrations in fresh marigold flowers vary from 4.0 mg/g in greenish yellow flowers to 800 mg/g in orange brown flowers. Gregory et al.

(1986) found that lutein ester concentrations in fresh marigold (*T. erecta*) flowers varied from 4 pg/g in greenish yellow flowers to 800 pg/g in orange brown flowers. Lutein and eight lutein esters are (2) lutein monomyristate, (3) lutein monopalmitate, (4) lutein monostearate, (5) unknown, (6) lutein dimyristate, (7) lutein myristate–palmitate, (8) lutein dipalmitate, (9) lutein palmitate–stearate, (10) lutein distearate content in two different parts (petals and calyces) of flower heads from different types of marigold belonging to the species *Tagetes patula* and *T. erecta* were evaluated (Piccaglia et al. 1998). Relevant quantitative differences were found among the marigold types which had a total content of pigments ranging from 17 to 570 mg/100 g in the petals and from 0.4 to 18.6 mg/100 g in the calyces. The following geometric isomers of native lutein diesters were separated by high-performance liquid chromatography–mass spectrometry (Tsao et al. 2004): *cis*-lutein isomeric dimyristate, myristate–palmitate, dipalmitate and palmitate–stearate diesters, as well as the rare combinations of both *trans*- and *cis*-lutein laurate–palmitate and *trans*- and *cis*-lutein myristate–stearate. The presence of the all-*trans*-lutein laurate–myristate, dimyristate, myristate–palmitate, palmitate–stearate and distearate diesters, reported by others, was also confirmed.

The following carotenoids were found in the flowers: lutein, lutein palmitate, lutein dimyristate, lutein myristate, lutein stearate and lutein distearate (Gau et al. 1983; Sowbhagya et al. 2013); lutein and lutein dipalmitate diesters, lutein myristate palmitate diesters, lutein lauristate myristate diesters, lutein dimyristate diesters, lutein palmitate stearistate diesters, lutein violaxanthin monoesters, lutein neoxanthin violaxanthin diesters and β -carotene and zeaxanthin (Breithaupt et al. 2001; Scalia and Francis 1989). The saponified extract of commercially prepared marigold flower (*Tagetes erecta*) extract was found to contain 93 % utilizable pigments consisting of all-*trans* and *cis* isomers of zeaxanthin (5 %), all-*trans* and *cis* isomers of lutein and lutein esters (88 %) (Hadden et al. 1999). Insignificant levels (<0.3 %) of lutein oxidation products were detected in the saponified extract.

This compositional determination is important for the application of marigold extract in nutritional supplements and increases its value as a poultry feed colourant because it contains more biologically useful lutein compounds than previously believed. The flowers of *T. erecta* cultivars were found to be rich in carotenoids (Kishimoto et al. 2007). Carotenoids in orange *Tagetes erecta* flowers were predominantly lutein and smaller quantities of violaxanthin and (9'Z)-neoxanthin. Total carotenoids in *T. erecta* cv. Orange Isis was 2,130 µg/g FW and in cv. Yellow Isis flowers was 48.4 µg/g FW (Kishimoto et al. 2007). Enzyme-mediated solvent extraction of carotenoids from marigold flower (*Tagetes erecta*) under optimal conditions afforded a carotenoid recovery yield of 97 % (Barzana et al. 2002). Erstwhile, extraction gave almost 50 % losses of the carotenoids depending on conditions for silaging, drying and solvent extraction.

The maximum amount of xanthophylls accumulated in the flowers with orange (or orange with claret spots) petals, where the content of carotenoids (recalculated for lutein) exceeded 5 mg/g of fresh petals against 1 mg/g for yellow and 0.2 mg/g for lemon-yellow flowers (Deineka et al. 2007). The marigold flowers of orange colour with claret spots were characterized by a high content of anthocyanins. The main component was cyanidin-3-glucoside; some samples also contained a significant amount (10–50 %) of another cyanidin derivative identical to that of cyanidin-3-glucoside acylated with malonic acid. The main acids of isolated lutein diester esters were myristic and palmitic acids (accounting for 85–90 % of the total sum of acid radicals); smaller fractions represented stearic and lauric acid radicals.

Total carotenoids in the fresh orange flowers of *T. erecta* was 1,304 mg/kg comprising 619 mg/kg carotenes and 685 mg/kg xanthophylls, whereas total carotenoids in the dried flowers were 4,397 mg/kg made up of flowers, 1,954 mg/kg carotenes and 2,443 mg/kg xanthophylls (Tinoi et al. 2006). The quantitative composition (mg/kg) of the carotenoids in the fresh petals was 85.5 mg β-carotene, 31.6 mg cryptoxanthin, 1,062 mg lutein, 43.7 mg violaxanthin, 53.7 mg

zeaxanthin and 34 mg unidentified. The quantitative composition (mg/kg) of the carotenoids in the dried petals was 65 mg β-carotene, 78.2 mg cryptoxanthin, 3,869 mg lutein, 92.8 mg violaxanthin, 166 mg zeaxanthin and 126 mg unidentified. The concentrations of lutein and zeaxanthin in 20 marigold (*T. erecta*) samples were assessed by saponification using traditional heater and microwave-assisted hydrolysis; the regression coefficient of lutein obtained by two methods was 0.9688 and that of zeaxanthin was 0.9527 (Liu et al. 2011). The limit of detection for lutein and zeaxanthin was 0.05 and 0.1 µg/ml, respectively, and the limit of quantification for lutein and zeaxanthin was 0.05 mg/100 g and 0.1 mg/100g, respectively. Pretreatment of marigold flowers with an aqueous enzyme solution (0.2 %), sodium hydroxide and citric acid solution resulted in improved resin, pigment yield and retention of carotenoid pigment during storage (Sowbhagya et al. 2013).

Vanegas-Espinoza et al. (2011) found that green callus from *T. erecta* leaf explants produced violaxanthin, lutein, zeaxanthin, β-carotene and esterified carotenoids, while yellow callus generated mainly lutein and esterified carotenoids, and brown callus produced lutein.

The carotenoid (3R,3'R,6'R)-lutein isolated from extracts of marigold flowers (*Tagetes erecta*) can be efficiently converted to (3R,3'S,6'R)-lutein (3'-epilutein) and (3R,3'R)-zeaxanthin (Khachik 2003). The two dietary carotenoid, (3R,3'R,6'R)-lutein and (3R,3'R)-zeaxanthin, and their metabolite (3R,3'S,6'R)-lutein (3'-epilutein) (3) accumulate in human serum, milk and ocular tissues and had been reported to play an important role in the prevention of age-related macular degeneration. Marigold (*Tagetes erecta*) flowers were found to show different levels of pigmentation caused by lutein, and several genes in the carotenoid biosynthetic pathway were identified: phytoene synthase (Psy), phytoene desaturase (Pds), lycopene β-cyclase (Lcy-b) and lycopene ε-cyclase (Lcy-e) (Del Villar-Martínez et al. 2010).

The dominant fatty acids of marigold (*T. erecta*) flower oleoresin were linoleic acid (>26.41 %), palmitic acid (>24.22 %) and oleic

acid (>20.12 %). Lutein esters, α -tocopherol, β -tocopherol, γ -tocopherol and δ -tocopherol were the dominant antioxidant compounds in the flower extracts (Gong et al. 2011).

Phenolic acids detected in the ethanol extract of *Tagetes erecta* flowers (mg/100 g DW) included: gallic acid, 14.74 mg; protocatechuic acid, 10.09 mg; *p*-hydroxybenzoic acid, 3.44 mg; chlorogenic acid, 13.64 mg; vanillic acid, 47.81; caffeic acid, 3.65 mg; syringic acid, 15.83 mg; *p*-coumaric acid, 253.05 mg; ferulic acid, 48.61 mg; sinapic acid, 531.39 mg; and total, 942.25 mg (Kaisoon et al. 2012). Flavonoid compounds found in the lyophilized hydrophilic extracts of *T. erecta* flowers (mg/100 g DW) included the following: rutin, 5.09 mg; myricetin, 54.81 mg; quercetin, 13.57 mg; apigenin, 8.41 mg; kaempferol 25.683.42 mg; and total, 165.3 mg.

Six oleanane-type triterpenoid esters were isolated from the golden flowers of *Tagetes erecta*, and their structures characterized as 3-*O*-[(9*Z*)-hexadec-9-enoyl]erythrodiol (1), 11 α ,12 α :13 β ,28-diepoxyoleanan-3 β -yl (9*Z*)-hexadec-9-enoate (2), 13 β ,28-epoxyolean-11-en-3 β -yl (9*Z*)-hexadec-9-enoate (3), 28-hydroxy-11-oxoolean-12-en-3 β -yl (9*Z*)-hexadec-9-enoate (4), 3-*O*-[(9*Z*)-hexadec-9-enoyl]- β -amyirin (5) and 11-oxoolean-12-en-3 β -yl (9*Z*)-hexadec-9-enoate (6) (Faizi and Naz 2004). Aerial oxidation (autoxidation) converted amyirin 1 into 2–4 and transformed amyirin 5 into 6. Also isolated were β -amyirin (7), erythrodiol (8) and ursolic acid. From *T. erecta* flowers, the following compounds were isolated: phenolic derivatives (syringic acid, gallic acid, 3,4-dihydroxybenzoic acid and 3,4-dihydroxy-5-methoxy-benzoic acid), terpenoid β -amyirin, steroids β -sitosterol and stigmasterol, and flavonoids (quercetagenin, quercetagenin-7-methyl ether and quercetagenin-5-methyl ether) (Huang et al. 2006). Also isolated from the flowers were the terpenoid dammarenediol 3-*O*-*n*-palmitate; flavonoid quercetagenin 3-*O*-glucoside; miscellaneous compounds 16*Z*,19*Z*-pentacosadienoic acid; and monolinoleoyl glycerol and vitamin E (Huang et al. 2007). Two new optical isomeric compounds named 3- α -galactosyl disyringic acid 15-a and 3- β -galactosyl disyringic acid 15-b were isolated from the flowers together with 22 other

compounds, and 20 of them were identified as tetratriacontane; dammarenediol II 3-*O*-*n*-palmitate; β -amyirin; 16*Z*,19*Z*-pentacosadienoic acid; uvaol; β -sitosterol; stigmasterol; vitamin E (α -tocopherol); 9*Z*,12*Z*,15*Z*-octadecatrien-1-ol; monolinoleoyl glycerol; syringic acid; 11, 3,4-dihydroxybenzoic acid; quercetagenin 7-methyl ether; quercetagenin; *n*-hexadecane; quercetagenin 5-methyl ether; 5,7-dimethoxy quercetin; gallic acid; 3,4-dihydroxy-5-methoxybenzoic acid; and quercetagenin 3-*O*-glucoside (Huang 2007). Xu et al. (2011) isolated 22 compounds from the flowers: β -sitosterol, β -daucosterol, 7 β -hydroxysitosterol, lupeol, erythrodiol, erythrodiol-3-palmitate, 1-[5'-(1-propyn-1-yl)-[2,2'-bithiophen]-5-yl]-ethanone, α -terthienyl, quercetagenin, quercetagenin-7-methyl ether, quercetagenin-7-*O*-glucoside, kaempferol, syringic acid, gallic acid, 3- α -galactosyl disyringic acid, 3- β -galactosyl disyringic acid, 6-ethoxy-2,4-dimethylquinoline, oploidiol, (3*S*,6*R*,7*E*)-hydroxy-4,7-megastigmadien-9-one, palmitin, ethylene glycol linoleate and *n*-hexadecane.

Twenty compounds were identified in the flower essential oil of *T. erecta*, and the major constituents were γ -cadinene, δ -cadinene and *cis*-caryophyllene and other sesquiterpenes (Shi et al. 1988). Analysis of composition of volatile flower oil of yellow *T. erecta* in Yanbian region by GC/MS showed *trans*-caryophyllene (33.18 %), β -cubebene (11.22 %), limonene (4.81 %), α -terpinolene (4.44 %), 1,3,6-octatriene, 3,7-dimethyl(*E*)- (3.36 %) and 2-cyclohexen-1-one,3 methyl-6-(1-methylethyl) (3.10 %) to be the main components (Leng et al. 1999). Forty-five constituents of the flower oil accounting for 94.0 % were identified, and the major constituents were limonene (6.9 %), terpinolene (4.7 %), (*Z*)-myroxide (7.9 %), piperitone (28.5 %), piperitenone (10.9 %), piperitenone oxide (7.2 %) and β -caryophyllene (7.0 %) (Krishna et al. 2004). Eighteen components were identified in the *T. erecta* flower essential oil: β -caryophyllene (15.2 %), limonene (11.7 %), methyl eugenol (12.3 %), (*E*)-ocimene (13.7 %), piperitone (91.2 %), piperitenone (8.1 %) and α -terpinolene (11.9 %) were the main components (Gutiérrez et al. 2006). Other compounds included linalool

(4.6 %), umbellulone (4.3 %), camphor (3.8 %), caryophyllene oxide (2.3 %), indole (1.8 %), *n*-undecane (1.7 %), citronellol (1.0 %), geraniol (0.9 %), and verbenone (traces). Twenty-five compounds were identified in the flower essential oil of *T. erecta* grown in Venezuela, of which linalool (22.5 %), 2-hexyl-1-decanol (18.3 %), piperitone (13.4 %), 4-terpinyl acetate (7.8 %) and caryophyllene (6.6 %) are the main components (Martínez et al. 2009). The volatile compounds identified in marigold (*Tagetes erecta* L.) flower oil were α -sesquiphellandrene, β -sesquiphellandrene, 2-methyl-6-(4-methyl cyclohexadienyl) hept-4-en-2-ol, myristoleic acid, and triecosane (Prasad et al. 2012).

Thirty-three components in *T. erecta* leaf and stem oil and 34 components in flower oil were identified (Sefidkon et al. 2004). The main characterized constituents were β -caryophyllene (8.5 and 35.2 %), terpinolene (18.4 and 6.3 %), (*E*)-ocimenone (12.6 and 9.8 %), (*Z*)- β -ocimene (10.4 and 13.7 %), piperitenone (10.4 and 2.6 %), (*Z*)-ocimenone (5.5 and 7.7 %), limonene (6.2 and 2.5 %), germacrene D (3.0 and 4.1 %), piperitone (4.2 and 0.6 %), (*Z*)-tagetone (3.7 and 1.5 %), fenchol (2.6 and 1.9 %), (*E*)-tagetone (2.2 and 1.3 %) and bicyclgermacrene (1.6 and 2.1 %) in leaf and stem oil and flower oil, respectively. Some components like *p*-cymene-8-ol, terpinen-4-ol, α -terpineole and verbenone were found only in stem and leaf oil, and some components like β -bourbonene, α -humulene, δ -cadinene, spathulenol and T-murolol were found only in flower oil.

A mixture of two tannin-related anomers 3,4-di-*O*-[syringate]- α -D-glucopyranose and 3,4-di-*O*-[syringate]- β -D-glucopyranose, together with syringic acid, was isolated from the alcohol extract of *Tagetes erecta* (Zhou et al. 2012). *T. erecta* flowers were found to have good amounts of syringic acid and β -amyrin (2.30 %, w/w and 0.06 %) (Maity et al. 2011).

Seven electrophysiologically active floral volatile compounds benzaldehyde, (*S*)-(-)-limonene, (*R,S*)-(+/-)-linalool, (*E*)-myroxide, (*Z*)- β -ocimene, phenylacetaldehyde and (*R*)-(-)-piperitone were detected in the air-entrained headspace samples of live flowers of *Tagetes*

erecta linked to a female *Helicoverpa armigera* (Bruce and Cork 2001).

Flavonoids found in the flowers and leaves included quercetagenin and kaempferitrin (Vasudevan et al. 1997).

Leaf/Plant Callus Phytochemicals

Twenty-seven compounds were found in *T. erecta* leaf oil (Machado et al. 1994). The major compounds were terpinolene (12.4 %), (*E*)- β -ocimene (13.1 %), piperitone (20 %) and limonene (11.0 %) (Machado et al. 1994). Indole was also found as a minor component. Forty-four constituents representing 94.1 % of the leaf oil were identified, and the major constituents of the leaf oil were limonene (7.6 %), terpinolene (11.2 %), (*Z*)-myroxide (4.2 %), piperitone (52.4 %) and piperitenone (5.0 %) (Krishna et al. 2004). Twenty-six components, accounting for 89 % of the total oil, were found in *T. erecta* leaf essential oil (Singh et al. 2003). The major constituents were (*Z*)- β -ocimene (42.2 %), dihydrotagetone (14.3 %), (*Z*)-tagetone (8.3 %), limonene (7.3 %), (*E*)-ocimenone (6.1 %) and (*Z*)-ocimenone (5.3 %). The essential oil of *T. erecta* leaves and inflorescences was found to contain mainly piperitone (35.9 %) and terpinolene (22.2 %) (Armas et al. 2012).

The essential oil from *T. erecta* differed largely from *T. minuta*, *T. tenuifolia* and *T. patula*, containing mainly limonene, β -caryophyllene and piperitone (Héthélyi et al. 1986).

Pyrethrins were isolated from the callus tissues of *T. erecta* (Sarin 2004).

Root Phytochemicals

Two mutants of *Tagetes erecta* were found to contain high amounts in the root extracts of the C13 monothiophene 2-(but-3-en-1-ynyl)-5-(penta-1,3-dienyl)-thiophene that was previously not found in *T. erecta* and also high amounts of two C13 bithienyls that were absent or present at low concentrations in the wild type (Jacobs et al. 1995). The mutant phenotype was also expressed

in 21 *Agrobacterium rhizogenes* transformed root clones derived from both mutants. Monothiophene found accumulating in the mutant was the common precursor for all bithienyl thiophenes in wild-type and mutant *Tagetes erecta*. Thiophene derivatives α -terthienyl and 5-butyl-2,2'-bithienyl were found in the roots (Vasudevan et al. 1997). A new bithienyl compound, 2-hydroxymethylnon-3-ynoic acid 2-[2,2']-bithiophenyl-5-ethyl ester from the roots of *T. erecta* (Gupta and Vasudeva 2010). Wang et al. (2002) isolated thiophene derivatives: 5,5'-dimethyl-2,2'-bithienyl; 5-vinyl-2,2'-bithiophene and 5-(3-butene-1-ynyl)-2,2'-bithiophene; and flavonoids: quercetagenin 3-*O*-glucoside and kaempferol. Liu et al. (2007) detected bacteriostatic alkaloids from the roots. Roots of *Tagetes* species (*T. erecta*, *T. filifolia*, *T. lucida*, *T. minuta*, *T. patula* and *T. tenuifolia*) had the highest diversity and contents of thiophenes (from 64 to 100 % of the total thiophene amount), with 5-(3-buten-1-ynyl)-2,2'-bithienyl (BBT) as the main component followed by 5-(4-acetoxy-1-butynyl)-2,2'-bithienyl (BBTOAc), 2,2':5',2''-terthienyl (α -T) and 5-(4-hydroxy-1-butynyl)-2,2'-bithienyl (BBTOH) (Marotti et al. 2010).

Antioxidant Activity

T. erecta flower essential oil was found to have antioxidant activity (Gutiérrez et al. 2006). However, the scavenging effects of *T. erecta* flower essential oil (100 mg/ml) on diphenyl-1-picrylhydrazyl (DPPH) radical were lower (71.5 %) than that of α -tocopherol (95.1 %) at 100 mg/ml. In the ABTS (2,2'-azino-bis-(3-ethylbenzotiazoline-6-sulphonic acid) model reaction, the essential oil exhibited inhibitory activity on the ABTS radical at 100 mg (57.3 %) less than α -tocopherol (70.5 %). The inhibitory effect of the essential oil (73.6 %) on 2-deoxy-2-ribose oxidation induced by $\text{Fe}^{3+}/\text{H}_2\text{O}_2$ was also lower than that for α -tocopherol (94.2 %). Significant differences in peroxide value were found between the control and the linoleic acid containing oil or antioxidant (α -tocopherol). The antioxidative activity of the

oil increased with concentration up to 12.5 $\mu\text{g}/\text{ml}$ and decreased at higher concentrations of oil, 200 mg/ml. The thiocyanate test showed that at a concentration of 50 mg/ml, the inhibition of oxidation of linoleic acid produced by oil was 71.1 %, respectively, as compared to the blank control and was less efficient than α -tocopherol (92.1 %). Ethanol flower extract of *Tagetes erecta* demonstrated antioxidant property in all the in-vitro models like 1,1-diphenyl-2-picrylhydrazyl (DPPH), reducing power and superoxide radical scavenging activity at different concentrations (Chivde et al. 2011b). It exhibited higher reducing power than the ascorbic acid standard but lower DPPH and superoxide scavenging activities.

Studies showed that the yield of oleoresin and total antioxidant activity of the marigold (*T. erecta*) extracts were affected by the pressure and temperature of SC-CO₂ (Gong et al. 2011). Lutein esters, α -tocopherol, β -tocopherol, γ -tocopherol and δ -tocopherol were the dominant antioxidant compounds in the extracts. In a comparative study of four edible flowers, the phenolics (mg GAE (gallic acid equivalent)/g DW) of the flowers were determined as follows: *Tagetes erecta* (212.9) > *Antigonon leptopus* (177.2) > *Bougainvillea glabra* (138.2) > *Cosmos sulphureus* (102.5) (Kaisoon et al. 2012). *Tagetes erecta* was found to have the highest antioxidant activity of the four edible flowers tested. Total reducing capacity (FRAP) ($\mu\text{mol Fe}^{2+}/\text{g DW}$) was ranked as *Tagetes erecta* (329.4) > *Bougainvillea glabra* (307.1) > *Antigonon leptopus* (281.9) > *Cosmos sulphureus* (99.9). The ORAC (oxygen radical absorbance capacity) ($\mu\text{mol TEq}$ (trolox equivalent)/g DW) ranks were *Antigonon leptopus* (491.9) > *Tagetes erecta* (394.2) > *Bougainvillea glabra* (276) > *Cosmos sulphureus* (214.8). Cellular antioxidant activity (CAA) ($\mu\text{M QE}$ (quercetin equivalent)/g DW) ranks were *Tagetes erecta* (413, most effective) > *Bougainvillea glabra* (859.6) > *Cosmos sulphureus* (966.1) > *Antigonon leptopus* (967.4).

The content of total phenolics and flavonoids in defatted marigold (*T. erecta*) extracts varied significantly with different solvents, and the extract by

ethyl alcohol (EtOH)/water afforded the highest content of total phenolics and flavonoids, 62.33 mg gallic acid equivalents (GAE)/g and 97.00 mg rutin equivalent (RE)/g, respectively (Gong et al. 2012). The results of the correlation analysis showed that the antioxidant activity as evaluated by ABTS, DPPH radical scavenging and FRAP assays was well correlated with the content of total phenolics and flavonoids ($R^2 > 0.900$). Gallic acid, gallicin, quercetagenin, 6-hydroxykaempferol-*O*-hexoside, patuletin-*O*-hexoside and quercetin were the dominant antioxidant compounds in the extracts, and quercetagenin was identified as the strongest antioxidant capacity

Lutein extracted and purified from marigold *Tagetes erecta* flower showed a greater antioxidant activity than the other two common carotenoids, β -carotene and lycopene as examined by the photochemiluminescence (PCL) assay and the β -carotene-linoleic acid model system (beta-CLAMS) (Wang et al. 2006).

Antidiabetic Activity

Inhibitory activity of lyophilized hydrophilic extracts obtained from four edible Thai flowers against α -glucosidase enzyme was found as: *Tagetes erecta* (98.51 % inhibition, IC_{50} 0.06 mg/ml) > *Antigonon leptopus* (58.24 % inhibition, IC_{50} 3.26 mg/ml) > *Bougainvillea glabra* (37.30 % inhibition, IC_{50} 5.21 mg/ml) > *Cosmos sulphureus* (32.32 % inhibition, IC_{50} 5.62 mg/ml) (Kaisoon et al. 2012).

Hypolipidemic Activity

Inhibitory activity of lyophilized hydrophilic extracts obtained from four edible Thai flowers against lipase activity was determined as *Cosmos sulphureus* (43.39 % inhibition, IC_{50} 4.60 mg/ml) > *Tagetes erecta* (41.61 % inhibition, IC_{50} 4.82 mg/ml) > *Bougainvillea glabra* (40.05 % inhibition, IC_{50} 5.14 mg/ml) > *Antigonon leptopus* (26.70 % inhibition, IC_{50} 7.87 mg/ml) (Kaisoon et al. 2012).

Antiproliferative/Cytotoxicity Activity

Tagetes erecta had highest antiproliferative activity among four edible flowers against one cancer cell line tested (Kaisoon et al. 2012). Antiproliferative activity (IC_{50} mg/ml) of polyphenolic extract against HC-29 (colorectal adenocarcinoma) cells was *Tagetes erecta* > (1.5) > *Bougainvillea glabra* (1.7) > *Antigonon leptopus* (2.4) > *Cosmos sulphureus* (5.2). Antiproliferative activity (IC_{50} mg/ml) of polyphenolic extract against AGS (gastric adenocarcinoma) cells was *Antigonon leptopus* (0.2) > *Bougainvillea glabra* (2.1) > *Tagetes erecta* (2.2) > *Cosmos sulphureus* (44.8). Antiproliferative activity (IC_{50} mg/ml) of polyphenolic extract against BI-13 (bladder cancer) cells was *Antigonon leptopus* (0.9) > *Bougainvillea glabra* (2.3) > *Tagetes erecta* (3.0) > *Cosmos sulphureus* (56.5).

The ethanol extract of *T. erecta* roots scavenged DPPH free radicals thereby exhibiting antioxidant activity with an IC_{50} of 35.9 μ g/ml and conferred marked cytotoxicity against the HeLa (LD_{50} of 164.28 μ g/ml) and PC-3 cell lines (LD_{50} of 407.3 μ g/ml) (Gupta et al. 2012). Among the 21 isolates obtained, T_3 showed antioxidant activity with IC_{50} of 11.56 μ g/ml and cytotoxicity with LD_{50} of 12.5 μ g/ml against HeLa and 30.25 μ g/ml against prostate PC-3 cell lines and was characterized as 2-ethynyl-5-(thiophen-2-yl) thiophene.

Antimicrobial Activity

T. erecta essential leaf oil completely inhibited the growth of *Fusarium oxysporum* and *Trichophyton mentagrophytes* (Rai and Acharya 1999). *T. erecta* root extracts (petroleum ether, chloroform, ethyl acetate, methanol and aqueous) exhibited significant antimicrobial activity against three Gram-positive and two Gram-negative bacterial and two fungal strains with MIC values ranging between 12.5 and 100 μ g/ml (Gupta and Vasudeva 2010). Methanol extract of *Tagetes erecta* at 40 mg/ml concentration was

found to have better inhibitory activity when compared to cold and hot aqueous extracts (Jain et al. 2012). The methanol extract exerted highest inhibition against *Aeromonas sobria*, *Aeromonas hydrophila*, *Staphylococcus aureus* (MTCC7405) and *Staphylococcus aureus* (clinical isolate) and was weakly inhibitory against *Bacillus subtilis*. Minimal inhibitory concentrations (MICs) were between concentrations of 20–160 mg/ml with both aqueous or methanol extracts.

T. erecta leaf extract exhibited high in vitro antibacterial activity against *Propionibacterium acnes* and *Acinetobacter baumannii* (mean activity index >0.9); moderate activity against *Enterococcus faecalis*, *Enterococcus faecium*, *Staphylococcus epidermidis*, *Staphylococcus aureus*, *Bacillus cereus*, *Erysipelothrix rhusiopathiae*, *Alcaligenes faecalis*, *Escherichia coli* and *Pseudomonas aeruginosa* (mean activity index 0.7–0.89); low activity against *Klebsiella pneumoniae* and *Salmonella enteritidis* (mean activity index <0.5); and negligible activity against (mean activity index <0.1) *Streptococcus pneumoniae*, *Streptococcus agalactiae* and *Staphylococcus saprophyticus* (Dasgupta et al. 2012).

Anti-wrinkle/Wound Healing Activity

The methanol extract of *T. erecta* flowers showed significant hyaluronidase and elastase inhibition with IC₅₀ of 11.70 and 4.13 µg/ml, respectively, and better MMP-1 inhibition compared to standard oleanolic acid (Maity et al. 2011). The isolated compounds syringic acid and β-amyrin were found to inhibit the enzymes comparable to oleanolic acid. The results suggested that the plant may be useful as an anti-wrinkle agent.

In both excision and burn wound models, a significant increase in the wound healing activity was observed in the adult albino mice treated with hydroalcoholic leaf extract of *Gymnema sylvestre* and *Tagetes erecta* and their combined extract (Hussain et al. 2011).

Hepatoprotective Activity

Ethyl acetate fraction of *T. erecta* ethanol flower extract administered orally to albino Wistar rats at the dose of 400 mg/kg orally significantly decreased the elevated serum marker enzymes, aspartate aminotransferase (AST), alanine aminotransferase (ALT) and alkaline phosphatase (ALP), and total bilirubin almost to the normal level compared to CCl₄-intoxicated group (Giri et al. 2011). Histological changes in the liver of rats treated with 400 mg/kg of the flower extract and CCl₄ showed a significant recovery except for cytoplasmic vascular degenerations around portal tracts, mild inflammation and foci of lobular inflammation. In another study, pretreatment of male rats with ethanol flower extract of *Tagetes erecta* (200 and 400 mg/kg) before CCl₄ injection reduced the biochemical markers of hepatic injury like SGPT, SGOT, ALP and bilirubin levels which were also confirmed by histopathological examination (Chivde et al. 2011a). The results indicated *T. erecta* flower extract to possess hepatoprotective which may be attributed to the quercetin-related flavonoids present in the flowers.

Antimutagenic Activity

Lutein and xanthophylls from Aztec Marigold (*T. erecta*) inhibited mutagenicity of 1-nitropyrene (1-NP) in a dose-dependent manner (González de Mejía et al. 1997a). In a dose–response curve of 1-nitropyrene (1-NP), the mutagenic potency was 4,317 revertants/nmol, and the dose of 0.06 µg of 1-NP/plate was chosen for the antimutagenicity studies. Lutein and the pigments were not toxic to *Salmonella typhimurium* tester strain YG1024 at the concentrations tested (0.002, 0.02, 0.2, 2.0 and 10 µg/plate). The percentages of inhibition of 1-NP mutagenicity were 72, 92 and 66.2 % for lutein (10 µg/plate), pigment for poultry use (10 µg/plate) and pigment for human use (2 µg/plate), respectively. Lutein had no effect on the DNA-repair system of strain YG1024. Pure lutein and xanthophylls from Aztec Marigold

flower (oleoresin and xanthophyll plus) inhibited the mutagenicity of aflatoxin B1 (AFB1) in a dose-dependent manner (González de Mejía et al. 1997b). The pigments were more efficient at inhibiting the AFB1 mutagenicity than pure lutein. The percentages of inhibition on AFB1 mutagenicity were 37, 66 and 76 % for lutein, oleoresin and xanthophyll plus at the dose of 2 micrograms/plate, respectively. Lutein had a modest effect on the DNA-repair system of YG1024. The results suggested that the inhibitory mechanism of lutein against AFB1 mutagenicity was most probably the result of a combination of the following events, formation of a complex between lutein and AFB1 and direct interaction between lutein and AFB1 metabolites, and finally that the lutein may also affect the metabolic activation of AFB1 by S9 and the expression of AFB1-modified *Salmonella typhimurium* DNA.

Larvicidal Activity

The larvicidal effects of essential oil from the leaves of *T. erecta* and some other plants were evaluated against *Anopheles stephensi*, *Culex quinquefasciatus* and *Aedes aegypti* (Namrata et al. 2000). *T. erecta* oil was found to be the most effective at lower concentration. Among the tested samples, the chloroform soluble fractions of *T. erecta* flowers showed the highest toxicity and consequently, the lowest LC₅₀ values (14.14, 17.06, 36.88 and 75.48 µg/ml) against all the instar larvae of *Culex quinquefasciatus* (Nikkon et al. 2011). *T. erecta* essential oil was active against third instar larvae of *Aedes aegypti*, with LC₅₀ of 79.78 µg/ml and LC₉₀ of 100.84 µg/ml (Marques et al. 2011). The main larvicidal compounds were piperitone (45.72 %), D-limonene (9.67 %) and piperitenone (5.89 %). The larvicidal thiophene contents were higher in the roots and flowers as demonstrated by high-performance liquid chromatography analysis.

No hatchability *Anopheles subpictus* was observed with hexane leaf extract of *T. erecta* at 1,000 ppm (Elango et al. 2010a). The percentages of effective oviposition repellency of hexane

and chloroform extracts were 81.53 and 72.77 % at 500 ppm. The methanol extract of *T. erecta* showed complete protection (repellency) against *Culex tritaeniorhynchus* in 90 minutes at 250 ppm (Elango et al. 2010b). The methanol leaf extract of *T. erecta* leaves showed good oviposition-deterrent, ovicidal and repellent activities against the malaria vector, *Anopheles subpictus* (Elango et al. 2011b). Mortality (no egg hatchability) was 100 % with the extract at 998.85 mg/l and maximum adult repellent activity was observed at 499.42 mg/l. After 24 hours of exposure, the highest adulticidal activity against *Anopheles subpictus* was observed in the methanol leaf extract of *T. erecta* (LD₅₀=89.83 ppm; LD₉₀=607.85 ppm); and effective EI (adult emergence inhibition) was EI₅₀=92.82 ppm and EI₉₀=582.59 ppm (Elango et al. 2011a). The results suggested that the leaf methanol extract of *T. erecta* had the potential to be used as an ideal eco-friendly approach for the control of *A. subpictus*.

Antiaging Activity

Studies showed that the administration of *Tagetes erecta* extract could effectively enhance the antioxidant capacity and delay D-galactose-induced aging in Wistar rats (Pei et al. 2007). The marigold extract significantly decreased MDA (malonaldehyde) content in the liver, kidney, heart, brain and prostate and other organs of the rats and significantly increased the activity of SOD (superoxide dismutase) and GSH-Px (glutathione peroxidase) compared to non-extract treated D-galactose-induced aged rats.

Keratolytic Activity

In a double-blind, placebo-controlled, 4-week study of 30 patients with painful plantar hyperkeratotic lesions, patients treated with an active paste pad of fresh marigold (*T. erecta*) plant combined with isopropyl alcohol (poultice dressing) showed a significant decrease in hyperkeratotic lesion width, length and pain when compared to the placebo group (Khan et al. 1996). The keratolytic

property of *Tagetes* was further confirmed in several published case studies (Khan and Evans 1996; Khan and Khan 2000). Patients receiving a similar therapy as previously described reported pain relief after 48 hours of the first dressing application. Further, patients who used the home therapy and orthotic control after the initial 8-week period had no recurrence of the lesions after 1 year.

Anticataract Activity

Quercetagenin extracted from *Tagetes erecta* inhibited aldose reductase of Wistar rat lens by 93.9 % at 10^{-4} M, 76.0 % at 10^{-5} M and 13.3 % at 10^{-6} M (Li et al. 1991).

Anthelmintic Activity

Studies showed that after 96 hours exposure, *T. erecta* acetonic plant extract produced 99.7 % lethal activity on the fourth larval stage of *Haemonchus contortus*, followed by *Castela tortuosa* hexane extract (85.8 %) and *T. erecta* methanol extract (58.3 %) (Aguilar et al. 2008).

Commercially available Aztec Marigold (*Tagetes erecta*) flower extract exhibited in vitro antioxidant activity and in vivo dose-dependent analgesic effect on acetic-acid-induced abdominal writhing (Bashir and Gilani 2008). The results supported the medicinal uses of Aztec Marigold as an antiinflammatory and analgesic.

Antiplasmodial Activity

Among *T. erecta* root extracts tested, ethyl acetate extract exhibited significant antiplasmodial efficacy with the 50 % inhibitory concentrations (IC_{50}) of 0.02 and 0.07 mg/ml against the chloroquine-sensitive and chloroquine-resistant strains of *Plasmodium falciparum*, respectively (Gupta and Vasudeva 2010). The new bithienyl compound, 2-hydroxymethyl-non-3-ynoic acid 2-[2,2']-bithiophenyl-5-ethyl ester, also showed significant schizonticidal activity against both

chloroquine-sensitive and chloroquine-resistant strains of *Plasmodium falciparum* with the IC_{50} values of 0.01 and 0.02 mg/ml.

Toxicity/Genotoxicity Studies

In the subacute toxicity, treatment of chloroform fraction of *T. erecta* flowers at 200 and 400 mg/kg doses to Long Evan's rats did not make any significant alterations on the haematological and biochemical parameters of rats compared with that of untreated controls (Nikkon et al. 2009b). Histopathological examination also showed no detectable changes in the liver, kidney, heart and lungs of chloroform fraction-treated rats. The study revealed that the chloroform fraction of *Tagetes erecta* had no toxic effects.

Lutein and its ester form isolated from marigold flowers (*Tagetes erecta*), administered orally to Wistar rats at doses of 4, 40 and 400 mg/kg body weight for 4 weeks for short-term toxicity study and 13 weeks for a subchronic toxicity study, did not produced any mortality, change in body weight, food consumption pattern, organ weight and other adverse side reactions (Harikumar et al. 2008). Administration of lutein and ester form did not alter the hepatic and renal function and did not produce any change in the haematological parameters and lipid profile. Histopathological analysis of the organs supported the nontoxicity of lutein and its ester form.

Using the standard Ames test in the presence and absence of S9 mix, lutein extracted and purified from marigold *Tagetes erecta* flower was not only found to be non-mutagenic at all doses (at 334, 668 and 1,335 μ g/plate), but it showed an anti-mutagenic effect in a dose-dependent manner (Wang et al. 2006). Similar results were found in a chromosome aberration test using Chinese hamster ovary cells for the evaluation of clastogenicity and anticlastogenicity of lutein at 66.8, 133.5 and 267.0 mg/l. The findings provided scientific evidence for the safe use and health beneficial effects of lutein.

The essential oils of *Tagetes* flowers were tested for their toxicological potential on mice; the results showed that the oils had a low toxicity

with a TD₅₀ 99.6 mg/kg for *T. erecta* and 112 mg/kg for *T. patula* (Martínez et al. 2009).

Acute and subchronic toxicity and mutagenicity studies in Wistar rats were carried out on Lutemax 2020, a lutein and zeaxanthin (including meso-isomer)-enriched product obtained from marigold (*Tagetes erecta*) flowers (Ravikrishnan et al. 2011). Lutein and zeaxanthin, naturally occurring carotenoids, had been shown to reduce the risk of cataracts and age-related macular degeneration. The results of mutagenicity testing in *Salmonella typhimurium* did not reveal any genotoxicity. The no-observed-adverse-effect level (NOAEL) for lutein/zeaxanthin concentrate was determined as 400 mg/kg bw/day, the highest dose tested.

Traditional Medicinal Uses

The flowers of *T. erecta* are officially listed in the Mexican Pharmacopoeia (Neher 1968). In Mexico, an infusion or decoction of the whole plant is taken internally for colds and respiratory ailments and as a stimulant. In Mexico, juice and leaves ground in water, are taken as an appetizer, aphrodisiac, diaphoretic, emetic, antipyretic, muscle relaxant, for liver problems, irregular menstrual flow, and dropsy (oedema). The flower and leaf decoction is taken as a carminative to relieve colic and intestinal gas and as a diuretic. An ointment is made from the leaves and juice and applied externally for malarial treatment. In Brazil, a whole plant infusion is taken for bronchitis and rheumatism, leaf infusion as vermifuge and a root infusion taken internally as a laxative (Neher 1968). In India, flower juice is taken internally as blood purifier and for piles, plant juice is used as ear drop and for eye infections, and a hot leaf poultice is used for boils and carbuncles (Neher 1968). *Tagetes erecta* flower is claimed to treat skin diseases like sores, burns, wounds, ulcers, eczema, and several other skin ailments (Maity et al. 2011). *T. erecta* is often used in sedation, depressurization, broadening bronchus, heat clearing and detoxicating, dissipating phlegm and stopping coughing, and spasmolysis and as an antiinflammatory (Huang

2007) It is widely used for upper respiratory tract infection, whooping cough, conjunctivitis, oral cavity inflammation, odontalgia, pharyngitis, vertigo, children infantile convulsion, amenorrhea, blood stasis, stomach ache, ulcerative carbuncle and rheumatism, among others.

Other Uses

The plant is popular as a house and garden ornamental throughout most temperate countries. The flowers are used as a source of yellow fabric dye known as 'egandai' or 'gendia' (Neher 1968). Fresh flowers are also used as cut flowers. Fresh and dry flowers can be used to dye wool, silk and cellulose fibres into shades of golden-yellow to orange and olive-green to bronze, depending on the mordant used. The plant contains phytochemical with broad biocidal activities against animal parasites, insect pests, fungi and nematodes.

The acetone extract of *T. erecta* exhibited antiparasitic activity against the sheep fluke *Paramphistomum cervi*, with LC₅₀ value of 425.73 ppm (Elango and Rahuman 2011). The pyrethrin mixture isolated from callus tissues exerted a 'knock down' effect against stored product pests, *Tribolium* spp. (Sarin 2004). Among the crude extracts and its fractions of the flower of *Tagetes erecta*, the chloroform fraction showed highest toxicity against both the larvae and adults of *Tribolium castaneum* followed by petroleum ether fraction and ethanol extract (Nikkon et al. 2009a). The LC₅₀ values of chloroform fraction against first, second, third, fourth, fifth and sixth instar larvae were 11.64, 14.23, 19.26, 29.02, 36.66 and 59.51 µg/cm² (72 hours), respectively, and for adults, the value was 65.93 µg/cm² (72 hours). *T. erecta* leaf essential oil showed 100 % mortality of white termite (*Odontotermes obesus* Rhamb.) at a dose of 6 µl/petri-plate after 24 hours of exposure, while at lower doses and shorter exposures, it showed diminished mortality rates (Singh et al. 2003). The oil only partially affected the mycelial growth of the tested fungi.

The plant was found to contain polyacetylenic thiopenes in their roots that conferred strong biocidal activity, useful for suppressing nematode

populations in the soil, and as sources of safe and natural pesticides (Marotti et al. 2010). *T. erecta* and *T. patula* were employed as a cover crop in Indian tea plantations to suppress nematodes (Neher 1968). Greenhouse studies by Ploeg (1999) demonstrated that preplanting of marigold cultivars of *Tagetes patula*, *T. erecta*, *T. signata* and a *Tagetes* hybrid all reduced galling and numbers of second-stage juveniles of *Meloidogyne incognita*, *M. javanica*, *M. arenaria* and *M. hapla* in subsequent tomato plantings. Natarajan et al. (2006) found that the aqueous extract of the whole plant was more efficacious than the stem extract and both were more efficacious than the root extract in controlling tomato root-knot nematode, *Meloidogyne incognita*. Studies found that population levels of root-lesion nematode (*Pratylenchus penetrans*) were consistently lower under marigolds (*Tagetes tenuifolia* cv. Nemakill and cv. Nemanon, *T. patula* ssp. *nana*, unidentified cv., and *T. erecta* cv. Crackerjack) compared to the other cover crops tested (Kimpinski et al. 2000). Correspondingly, average potato tuber yields were significantly higher (8–14 %) when potato followed marigolds. Results of other studies suggested that *Pratylenchus penetrans* population density may be significantly reduced when marigold (*Tagetes erecta*) were double cropped with potatoes or tomatoes (Alexander and Waldenmaier 2002). During the 3 years of the study, *P. penetrans* soil population density declined by an average of 93 % from the preplant level when marigold was grown in rotation with potato and by 98 % when marigold was grown in rotation with tomato. There was a significant reduction in the number of *P. penetrans* found in both potato and tomato roots when the crops followed marigolds. The ethanol root extract of *T. erecta* exerted >90 % mortality rate of the nematode, *Bursaphelenchus xylophilus* (Ju et al. 2010).

The essential oil of *Tagetes erecta* leaves exhibited complete inhibition of growth of *Pythium aphanidermatum*, the damping-off pathogen, at a concentration of 2,000 ppm (2.0×10^3 µl/l) dilution (Kishore and Dwivedi 1991). During pot trials, the oil indicated its efficacy for controlling the damping-off of seedlings of tomato up to 50 %.

Comments

The major producers of *Tagetes erecta* are Mexico, Peru, Ecuador, Argentina, and Venezuela; minor producers are India, South Africa, and Zambia. Refer also to notes under other *Tagetes* species.

Tagetes lucida

Scientific Name

Tagetes lucida Cav.

Synonyms

Tagetes anethina Sessé & Moc., *Tagetes florida* Sweet, *Tagetes gillettii* De Wild., *Tagetes lucida* (Sweet) Voss, *Tagetes lucida* f. *florida* (Sweet) Voss, *Tagetes lucida* subsp. *schiedeana* (Less.) Neher, *Tagetes pineda* La Llave, *Tagetes schiedeana* Less, *Tagetes seleri* Rydb.

Family

Asteraceae

Common/English Names

Cloud Plant, Mexican Mint Marigold, Mexican Tarragon, Mint-Marigold, Spanish Tarragon, Sweet Scent Marigold, Sweet Scent Mexican Marigold, Sweet Mace, Texas Tarragon, Winter Tarragon

Vernacular Names

Chinese: Tian Wan Shou Ju

Czech: Aksamitník Světlý

Danish: Mexikansk Esdragon

Eastonian: Lääkiv Peiulill

German: Glänzende Samtblume, Samtblume, Winterestragon, Mexicanischer Estragon

Finnish: Rohtosamettikukka, Tuoksusamettikukka

French: Tagète, Tagète Luisante, Estragon Du Mexique

Mexico: Anis, Anisillo, Curucumin, Hierba Anis, Hierba De Santa Maria, Hierbanis, Pericón, Santa Maria, Tzitziqui, Yerba De Nube, Yahutli (**Ancient Aztec**)

Polish: Aksamitka Yahutli

Russian: Meksikanski Estragon

Spanish: Anisillo, Hierba Anis, Pericón, Perriquillo, Yauhtli, Yerba Anis

Swedish: Mexikansk Dragon

Origin/Distribution

The plant is native to Central America (Mexico, Honduras and Guatemala) and South America. It thrives in the south of the United States and in México and is grown in many warm temperate areas worldwide. It is cultivated as an ornamental in the highlands in Java.

Agroecology

It is an aromatic herb distributed naturally from Mexico to Honduras, at elevations between 1,000 and 2,000 m. A robust perennial herb grown as an annual. It requires full sun or partial shade and needs well-drained, moderately fertile soil,

growing well in clayey and sandy soils. It is fairly drought tolerant and frost sensitive; hard freezes will kill it to the ground. It is easily propagated through stem cuttings.

Edible Plant Parts and Uses

Leaves and flowers are edible (Hedrick 1972; Facciola 1990; Brown 2011). Petals are used as condiments. Flowers are used in salads. The anise-scented foliage is used in salads, soups, sauces, stews and poultry and fish dishes. Mexican Marigold is good for bouquet garni for flavoured butter and herbed vinegar. The dried leaves and flowering tops are brewed into a pleasant, soothing, anise-flavoured tea which is a very popular drink in Latin America. The leaves were an important flavouring of 'chocolatl', the foaming cocoa-based drink of the Aztecs. The petals are used as a condiment. The natives in Mexico prepare a tea from the shoots.

It is cultivated commercially in Costa Rica as a spice herb; it contains an oil having an anise-like odour, and the fresh aerial parts of this plant are sold in the supermarket as a substitute of tarragon (*Artemisia dracunculus* L.).

Botany

A half-hardy semi-woody herb to subshrub that grows 46–76 cm high and 48 cm spread. The plant is bushy with many smooth, upright, unbranched stems. The leaves are opposite, linear to oblong, about 7.6 cm long, and shiny medium green and finely toothed margin, acute and tapering base, sessile and glandular (Plates 1, 2 and 3). Bruised leaves have a sweet tarragon-like smell with overtones of anise. In summer it bears terminal clusters of small yellow to orange flower heads on the ends of the stems. The flowers are about 1.5 cm in diameter, bisexual comprising a single whorl of 3–5 (–7) ray florets with yellow to orange-yellow corollas, and numerous disc florets in the centre of the capitulum (Plates 1 and 2).

Nutritive/Medicinal Properties

Guzmán and Manjarrez (1962) reported methyl eugenol (80 %) and methyl chavicol (12 %) as the major components of *T. lucida* plant oil. Anethole (23.8 %), eugenol (24.3 %) and methyl chavicol (33.9 %) were reported as major constituents (Bicchi et al. 1994). From a methanol extract of the entire plant collected in Mexico, four coumarins were isolated (Rios and Flores 1976). Also, three bithienyls [5-(3-buten-1-ynyl)-2,2'-bithienyl, 5-(4-hydroxy-1-butyryl)-2,2'-bithienyl, 5-(4-acetoxy-1-butyryl)-2,2'-bithienyl] and α -terthienyl were isolated from roots of the plant (Bohlmann et al. 1973). Bicchi et al. (1997) identified 53 compounds in the essential oil of *T. lucida* aerial plant parts, and anethole (23.8 %), methyl eugenol (24.3 %) and estragole (33.9 %) were the major constituents. Cicció (2004) identified 30 compounds from the oils of *T. lucida* flowers, stems and leaves: methyl chavicol (95–97 %) was the major constituent, with minor quantities of the monoterpenes, β -myrcene (0.6–1.8 %), (*E*)- β -ocimene (0.2 %) and linalool (0.2–0.3 %). The sesquiterpene hydrocarbons

amounted to only about 1–2 %: β -caryophyllene (0.2–0.3 %), (*E*)- β -farnesene (0.3–0.9 %), germacrene-D (0.2–0.5 %) and (*E,E*)- α -farnesene (0.1–0.3 %). The flower oil also contained two bithienyls, 5'-methyl-5-(3-buten-1-ynyl)-2,2'-bithienyl (0.1 %) and 5-(3-penten-1-ynyl)-2,2'-bithienyl *n*-heneicosane (0.8 %) and δ -cardinene 0.1 % as minor constituents.

Tagetes lucida was reported to contain the following flavonoids: isorhamnetin and its 7-*O*-glucoside, a quercetagenin 3-*O*-arabinosylgalactoside and patuletin (Abdala 1999). Céspedes et al. (2006) isolated seven coumarins, namely, 7,8-dihydroxycoumarin, umbelliferone (7-hydroxycoumarin), scoparone (6,7-dimethoxycoumarin), esculetin (6,7-dihydroxycoumarin), 6-hydroxy-7-methoxycoumarin, herniarin (7-methoxycoumarin) and scopoletin (6-methoxy-7-hydroxycoumarin), and three flavonoids, patuletin, quercetin and quercetagenin, from CH_2Cl_2 and MeOH extracts from aerial plant parts of *T. lucida*. Additionally, 6,7-diacetoxycoumarin, 6-methoxy-7-acetylcoumarin and 6-acetoxy-7-methoxycoumarin derivatives were synthesized. 8-Methoxypsoralen; 8-acetyl-7-hydroxycoumarin; 7,8-dihydroxy-6-methoxy-coumarin; 6,7-dimethoxy-4-methylcoumarin; 5,7-dihydroxy-4-methylcoumarin; 4-hydroxycoumarin; 4-hydroxy-6,7-dimethylcoumarin; naringenin; glycoside-7-rhamnonaringin and rutin were commercially obtained. The following phenylpropanoids scopoletin and 7-methoxycoumarin were reported from the plant by Oranday et al. (2008).

Roots of *Tagetes* species (*T. erecta*, *T. filifolia*, *T. lucida*, *T. minuta*, *T. patula* and *T. tenuifolia*) were found to have the highest diversity and contents of thiophenes (from 64 to 100 % of the total thiophene amount), with 5-(3-buten-1-ynyl)-2,2'-bithienyl (BBT) as the main component followed by 5-(4-acetoxy-1-butyryl)-2,2'-bithienyl (BBTOAc), 2,2':5',2"-terthienyl (α -T) and 5-(4-hydroxy-1-butyryl)-2,2'-bithienyl (BBTOH) (Marotti et al. 2010). *Tagetes lucida* and *T. tenuifolia* possessed the highest amounts of total thiophenes (6717.3 and 6452.5 mg/kg dry weight, respectively). Thiophenes are polyacetylenic compounds that possess strong

biocidal activity, useful for suppressing nematode populations in the soil and as sources of safe and natural pesticides.

Antioxidant Activity

Methanol extract of *Tagetes lucida* leaves yielded a new flavonol glycoside, quercetagenin 3,4'-dimethyl ether 7-*O*- β -D-glucopyranoside; two new phenolic acids, 3-(2-*O*- β -D-glucopyranosyl-4-methoxyphenyl)propanoic acid and its methyl ester; and known flavonols, aromatic acids and 7-methoxycoumarin (Aquino et al. 2002). Using the DPPH test, the extract and some of its constituents showed significant free radical scavenging effect in comparison to α -tocopherol and standard flavonols. The antioxidant activity of the essential oil from *Tagetes lucida* showed a low mean effective concentration (EC₅₀), with value of 37.9 μ g/ml (Olivero-Verbel et al. 2010). The main component of the oil was estragole (95.7%).

Antidepressant Activity

Tagetes lucida had been reported to have antidepressant property in rats. Studies reported that the aqueous extract (10, 50, 100 mg/(kg/day)) of *T. lucida* significantly reduced immobility of the rats and increased swimming without affecting climbing behaviour in the forced swimming test (Guadarrama-Cruz et al. 2008). Similar doses were not able to modify neither the motor activity nor the on male sexual behaviour. *T. lucida* has been used in Mexican traditional medicine for the treatment of different central nervous system (CNS) diseases, in particular for depression. Of the different extracts of *T. lucida* (methanol, hexane, dichloromethane and aqueous, 10 and 50 mg/kg), only the aqueous extract of *T. lucida* administered to rats at a dose of 50 mg/kg significantly reduced immobility behaviour and increased swimming in the forced swimming test similar to fluoxetine (Gabriela et al. 2012). An antidepressant effect was observed after 7 days of treatment with the aqueous extract. Pretreatment with PCPA, an inhibitor of serotonin synthesis

(100 mg/kg/day for 4 consecutive days), inhibited the antidepressant effect of both *T. lucida* and fluoxetine. Further, the aqueous extract of *T. lucida*, administered p.o., did not produce lethality or any significant changes in behaviour. They concluded that the aqueous extract of *T. lucida* manifested an antidepressant-like effect in the forced swimming test mediated by the serotonergic system, with no adverse effects when administered p.o.

Antimicrobial Activity

Several papers also reported on the antimicrobial activity of the aerial plant parts of *T. lucida*. Caceres et al. (1990) reported that *T. lucida* was one of ten plants that exhibited the best antibacterial activity against five enterobacteria pathogenic to man (enteropathogenic *Escherichia coli*, *Salmonella enteritidis*, *Salmonella typhi*, *Shigella dysenteriae* and *Shigella flexneri*). They also reported that *T. lucida* exhibited antimicrobial activity against three Gram-positive bacteria causing respiratory infections (*Staphylococcus aureus*, *Streptococcus pneumoniae* and *Streptococcus pyogenes*) (Caceres et al. 1991). The methanol/chloroform extract of *T. lucida* aerial plant parts was active against *Aeromonas hominis* and *Pseudomonas aeruginosa*, while the chloroform extract was active against the same bacteria and also against *Escherichia coli* and *Enterobacter alcalifaciens* (Capunzo et al. 2003). The petroleum ether extract did not show antibacterial activity. The ethyl acetate extract of *T. lucida* showed antibacterial activity against *Shigella boydii*, *Staphylococcus aureus*, *Staphylococcus epidermidis*, *Pseudomonas aeruginosa*, *Bacillus subtilis*, *Sarcina lutea* and four strains of *Vibrio cholerae* (Hernández et al. 2006). The bioactive compound 5,7,4'-trimeoxyflavone was identified.

Céspedes et al. (2006) isolated seven coumarins, namely, 7,8-dihydroxycoumarin (4), umbelliferone (7-hydroxycoumarin) (5), scoparone (6,7-dimethoxycoumarin) (7), esculetin (6,7-dihydroxycoumarin) (11), 6-hydroxy-7-methoxycoumarin (12), herniarin (7-methoxycoumarin)

(13) and scopoletin (6-methoxy-7-hydroxycoumarin) (14), and three flavonoids, patuletin (18), quercetin (19) and quercetagenin (20), from CH_2Cl_2 and MeOH extracts from aerial plant parts of *T. lucida*. In addition, 6,7-diacetoxycoumarin (15), 6-methoxy-7-acetylcoumarin (16) and 6-acetoxy-7-methoxycoumarin (17) derivatives were synthesized. 8-Methoxypsoralen (1), 8-acetyl-7-hydroxycoumarin (2), 7,8-dihydroxy-6-methoxycoumarin (3), 6,7-dimethoxy-4-methylcoumarin (6), 5,7-dihydroxy-4-methylcoumarin (8), 4-hydroxycoumarin (9), 4-hydroxy-6,7-dimethylcoumarin (10), naringenin (21), glycoside-7-rhamnonaringin (22) and rutin (23) were commercially obtained. The most active compounds against Gram-positive and Gram-negative bacteria (*Escherichia coli*, *Proteus mirabilis*, *Klebsiella pneumoniae*, *Salmonella typhi*, *Salmonella* sp., *Shigella boydii*, *Shigella* sp., *Enterobacter aerogenes*, *Enterobacter agglomerans*, *Sarcina lutea*, *Staphylococcus epidermidis*, *Staphylococcus aureus*, *Yersinia enterocolitica* and *Vibrio cholerae* (three El Tor strains, CDC-V12, clinic case, and INDRE-206 were obtained from contaminated water), and *V. cholerae* (NO-O1)) were the dihydroxylated coumarins: 7,8-dihydroxy-6-methoxycoumarin and 7,8-dihydroxycoumarin. In addition, compounds 2–4, 6, 7 and 11 showed inhibitory activity against *Vibrio cholerae*, a key bacterium in the contaminated water; compounds 2–4 were the most active. Coumarins were the most effective compounds against Gram-negative bacteria. The extract MeOH/ CH_2Cl_2 (1: 4) M2 at 0.4 $\mu\text{g}/\text{disc}$ inhibited the growth of *Escherichia coli* and *Proteus mirabilis* (40 %), *Klebsiella pneumoniae* (31.1 %), *Salmonella* sp. (35.5 %) and *Shigella* sp. (0 %) at 72 hours of culture. The dimethoxy compounds 6 and 7 showed potent activity against fungal strains (*Aspergillus niger*, *Penicillium notatum*, *Fusarium moniliforme*, *Fusarium sporotrichum*, *Rhizoctonia solani* and *Trichophyton mentagrophytes*), especially *Trichophyton mentagrophytes* and *R. solani* (100 % of inhibition at 125.0 and 250.0 $\mu\text{g}/\text{ml}$, respectively).

The methanol-chloroform and ethyl acetate extracts of *T. lucida* exhibited pronounced anti-

fungal activity against fungi *Candida albicans*, *Colletotrichum lindemuthianum*, *Mucor circinelloides*, *Saccharomyces cerevisiae* and *Sporothrix schenckii* (Damián-Badillo et al. 2008b).

Forty volatile compounds were identified in the leaf essential oil, of which estragole (96.8 %) was the major constituent (Regalado et al. 2011). The essential oil exhibited significant antioxidant activities as evaluated by two different in-vitro assays (DPPH and TBARS), and significant activities were evidenced. The preliminary screening of its antiparasitoid, antibacterial, antifungal and antiviral activities was carried out against *Plasmodium berghei*, *Staphylococcus aureus*, *Pseudomonas aeruginosa*, *Escherichia coli*, *Candida albicans*, *Acinetobacter lwoffii* and *Enterobacter aerogenes* and against strains HHV 1 and HHV 2. The essential oil showed moderate activity against *P. berghei* and *E. coli*.

Anticancer/Cytotoxic Activity

The hexane leaf extract of *Tagetes lucida* exhibited marked cytotoxic activity (Mejia-Barajas et al. 2010). The bioactive compounds isolated from the leaf extract were 7-methoxycoumarin and 6,7-dimethoxycoumarin; both compounds caused cytotoxicity in *Artemia salina*, with LC_{50} values of 28 and 238 $\mu\text{g}/\text{ml}$, respectively. The ethanol and aqueous extracts of *T. lucida* were found to be cytotoxic ($\text{ED}_{50} < 20 \mu\text{g}/\text{ml}$) against T47D cell line (human breast cancer) and the aqueous extract from *T. lucida* cytotoxic to HeLa (human cervix cancer) cell line (Vega-Avila et al. 2009). *T. lucida* (aerial parts) essential oil showed cytotoxicity (LC_{50} 24 hours = 22.4 $\mu\text{g}/\text{ml}$, LC_{50} 48 hours = 17.63 $\mu\text{g}/\text{ml}$) on the brine shrimp *Artemia franciscana* assay (Olivero-Verbel et al. 2010).

Larvicidal Activity

Coumarins, scopoletin and 7-methoxycoumarin isolated from the plant exhibited larvicidal activity against the malarial vector, *Aedes aegypti* (Oranday et al. 2008).

Traditional Medicinal Uses

The leaves and whole plant are digestive, diuretic, febrifuge, hypotensive, narcotic, anaesthetic, sedative and stimulant (Bown 1995). It is used internally in the treatment of sore eyes, diarrhoea, nausea, indigestion, colic, hiccups, rheumatism, malaria and feverish illnesses. Externally, it is used to treat scorpion bites and to remove ticks.

T. lucida was one of the most widely used medicinal plants in western Mexico (Neher 1968). The whole plant is dried and made into a tea by Indians for treating scorpion bites, fever, ague, diarrhoea and also as an aphrodisiac. The leaves are macerated in water and taken internally to cure hiccups. In ceremonies, the Huichol Indians from the Sierra Madre Mountains reportedly have visions when smoking the herb in combination with the consumption of fermented Tarragon tea, which is prepared the same way 'Sinicuichi' is prepared (Siegel et al. 1977). People who had been struck by lightning were treated with extracts of *Tagetes lucida*.

T. lucida is one of the plants most used by the Latin American population for the treatment of gastrointestinal disorders (Giron et al. 1991; Damián-Badillo et al. 2008b).

In Mexico, fresh herbage of *Tagetes lucida* is used as a tea for abdominal pains, to calm stomachs, to relax nerves and to alleviate the symptoms of a hangover (Bye and Linares 1983). In Mexico, juice that has been pressed from the herbage or crushed leaves are mixed with water or wine and drunk as an aphrodisiac. A tea of the plant is also used as a stimulant. It has been recognized since Spanish Colonial times that *Tagetes lucida* has aphrodisiac effects. In Mexico, it is believed that the herbage promotes lactation (Jiu 1966). It is also used as a bath additive to treat rheumatism (Siegel et al. 1977).

In India, juice from freshly pressed leaves is administered to treat eczema. In Argentina, a decoction of the leaves is drunk for coughs, and when applied topically on the skin, it is well known as an insect repellent.

Other Uses

Tagetes lucida is an aromatic herb distributed naturally in Central and South America, where it is used as a spice, for medicinal purposes, as insecticide, for religious purposes and as ornamental plant (Olivero-Verbel et al. 2010).

In Mexico and Guatemala, *Tagetes lucida* has played an important role in social, cultural and religious rites since the Aztec era till today (Kaplan 1960; Neher 1968; Diaz et al. 1977). The flowers are prominently used in religious Catholic and indigenous festivities especially in ceremonies for the dead and in the Catholic All Souls Days (Kaplan 1960). *Tagetes* flowers are commonly used for arcs and altar decorations. Even today, many Mexican Indians burn the dried foliage of *Tagetes lucida* as an incense on their home altars and during public ceremonies (Neher 1968). They would sprinkle a powder of the plant into the faces of prisoners of war who were to be burned as sacrifices, so that they would be sedated during their ordeal. The Aztecs referred to *Tagetes lucida* as 'yahutli', 'plant of the clouds' (Siegel et al. 1977). The Huichol Indians of the Sierra Madre of Mexico would smoke dried herbage of *T. lucida* (commonly referred to as *tumutsáli*) alone or mixed with tobacco from *Nicotiana rustica*. This smoking mixture, although sometimes smoked recreationally, does have ceremonial importance and hallucinogenic effects. It is reported to be smoked as a rite of passage in sexual shamanic rituals, most likely due to its aphrodisiac effects. Bundles of the dried herbage are placed as offerings in temples, administrative buildings and sacred sites (Siegel et al. 1977). The dried leaves and flowers are also smoked in cigarettes made from corn husks, often in combination with the ingestion of peyote (*Lophophora williamsii*). The combinations of smoking the herbage of *Tagetes lucida* along with consuming peyote, 'tesquino' or 'nawa' (fermented maize beverage), or homemade 'ci' or 'soter' (cactus liquor) are believed to produce very active, vivid hallucinations.

The plant contains polyacetylenic thiophenes which possess strong biocidal activity, useful for

suppressing nematode populations in the soil and as sources of safe and natural pesticides (Marotti et al. 2010).

Mexican Tarragon is an attractive landscape ornamental often used in perennial borders. Secretions from the roots of growing plants have an insecticidal effect on the soil and are reported to be effective against nematodes, keeled slugs and couch grass weed. The growing plant also has a repellent effect on various insect pests such as the asparagus beetle and bean weevils. The dried plant is burnt as an incense and to repel insects. A yellow dye obtained from the flowers is used for textile.

Epoxidation of dimethyldioxirane with the main constituents of the essential oils obtained from *Tagetes lucida*, *Cymbopogon citratus*, *Lippia alba* and *Eucalyptus citriodora* generated modified epoxides with potential uses in several areas of medicine and industry (Veloza et al. 2011).

Comments

Dried leaves will retain some of their distinctive sweet aroma but are not as good as fresh leaves. It is better to freeze the leaves or store in vinegar.

Vietnamese: Cúc Cà Cuống, Vạn Thọ Nhỏ, Cúc Vạn Thọ Lùn

Origin/Distribution

The species is native to the Americas—Central (Mexico and Guatemala) and southwestern United States (Arizona, New Mexico and southwest Texas). It is cultivated and has naturalized elsewhere.

Agroecology

In its native range, it is found from near sea level up to altitude of 1,350 m. It is frost tender and is quite adaptable to poor soils, heat, humidity and especially drought but not adaptable to shade or water-logged sites. It thrives best in full sun, on well-drained sandy or loamy soils.

Edible Plant Parts and Uses

Flowers and leaves are edible (Kunkel 1984; Facciola 1990). Flowers are used in refreshing drinks and the leaves are used for flavouring food. The dried flowers are used as an adulterant of saffron (*Crocus sativus*) and used for colouring foods yellow. The essential oil is used as a food flavouring, though it is inferior to the oil obtained from *T. minuta* (Bown 1995).

Botany

A small, bushy, erect, branched, glabrous, herbaceous annual, 25–100 cm high with a tap root. Leaves 4–7 cm long, deeply sinuate to the midrib with linear-lanceolate segments with serrated margins (Plates 1, 2, 3, 4 and 5). Capitulum solitary and terminal, 1.5–3 cm across, on 30–15 cm long peduncle. Single flower heads have widely spreading ray florets, but double-flowered head has mounding ray florets in the shape of globular,

Plate 1 Orangy red flowers and leaves

Plate 2 Variegated reddish-brown-yellow flowers and leaves

Plate 3 Yellow flowers and leaves

flabellate button flower heads. Ray florets 5–9 (25+), female, ligulate, flabellate to oval-quadrangle, yellow, orange to red or variegated

Plate 4 Orangey flowers and leaves

Plate 5 Yekkow double-flowered globose flowers and leaves

blends of red-brown, yellow/red-brown (Plates 1, 2, 3, 4 and 5). Disc florets numerous, tubular, bisexual. Fruit 6–11 mm black achene, with scaly pappus.

Nutritive/Medicinal Properties

Flower Phytochemicals

Rop et al. (2012) reported that edible flowers of *Tagetes patula* had a dry matter content (%w/w) of 9.68 %, crude protein of 2.95 g/kg and the following elements (mg/kg fresh mass (FM)): P 478.25 mg, K 3808.72 mg, Ca 346.85 mg, Mg 205.19 mg, Na 114.32 mg, Fe 8.72 mg, Mn 7.86 mg, Cu 1.09 mg, Zn 13.29 mg and Mo 0.37 mg. The flowers had total antioxidant capacity of 6.70 g ascorbic acid equivalents/kg FM, total phenolic content of 4.58 g gallic acid/kg FM and total flavonoid content of 1.90 g rutin/kg FM. The flowers of *T. patula* cultivars were found to be rich in carotenoids (Kishimoto et al. 2007). Carotenoids in orange *Tagetes patula* flowers were lutein, antheraxanthin, zeaxanthin and violaxanthin. Total carotenoids in *Tagetes patula* Safari Tangerine (orange flowers) were 2019.6 µg/g FW, in Bonanza orangea (orange flowers) 1957.7 µg/g FW, in Safari Yellow (yellow flowers) 312.3 µg/g FW and in Bonanza yellow 270.3 µg/g FW (Kishimoto et al. 2007). The maximum amount of xanthophylls accumulated in the flowers with orange (or orange with claret spots) petals, where the content of carotenoids (recalculated for lutein) exceeded 5 mg/g of fresh petals against 1 mg/g for yellow and 0.2 mg/g for lemon-yellow flowers (Deineka et al. 2007). The Marigold flowers of orange colour with claret spots were characterized by a high content of anthocyanins. The main component was cyanidin-3-glucoside; some samples also contained a significant amount (10–50 %) of another cyanidin derivative identical to that of cyanidin-3-glucoside acylated with malonic acid. The main acids of isolated lutein diester were myristic and palmitic acids (accounting for 85–90 % of the total sum of acid radicals); smaller fractions represented stearic and lauric acid radicals.

Lutein (1) and eight lutein esters: (2) lutein monomyristate, (3) lutein monopalmitate, (4) lutein monostearate, (5) unknown, (6) lutein dimyristate, (7) lutein myristate-palmitate, (8) lutein dipalmitate, (9) lutein palmitate-stearate, (10) in two different parts (petals and calyces) of flower heads from different types of Marigold belonging to the species *Tagetes patula* and *T. erecta* were evaluated (Piccaglia et al. 1998). Relevant quantitative differences were found among the Marigold types which had a total content of pigments ranging from 17 to 570 mg/100 g in the petals and from 0.4 to 18.6 mg/100 g in the calyces. Marigold (*T. patula*) flowers were found to be a rich source of carotenoids mainly lutein (Bhattacharyya et al. 2008). Among the solvents methanol showed the highest extractability (52.51 %). Of three varieties (orange, yellow and red) the orange variety contained the maximum amount of lutein 154.96 mg/g of extract. The fatty acid composition of the ester fraction was determined, and saturated fatty acid content was maximum (about 75 %) and unsaturated fatty acid was about 25 %. The lutein ester was also reacted with capric acid (C₁₀) in presence of *Mucor miehei* immobilized lipase, and about 17.5 % C₁₀ fatty acid was incorporated to produce modified lutein for application in various functional foods.

A new acyclic monoterpene glucoside, 2-methyl-6-methylen-2,7-octadiene-1-*O*- β -D-glucopyranoside, and known compounds, helenien, xanthophyll, patuletin and patuletin, were isolated from *Tagetes patula* flowers (Garg et al. 1999a, b). One triterpene lupeol [lup-20-(2a)-en-3 β -ol] and steroids, cholesterol, β -sitosterol (24-*R*-stigmast-5-ene-3 β -ol) and stigmasterol [24-(*S*)-stigmast-5,22*E*-dien-3 β -ol] were isolated from the flowers (Bano et al. 2002). A tetrahydro- β -carboline alkaloid, (+) jafrine, was isolated from the petroleum ether extract of flowers (Faizi and Naz 2002). The transformation of jafrine as well as 4-*N*-acetyl tetrahydroharmine into 2-acetyl tryptamine derivatives by autoxidation was observed.

The flavonol, patuletin, was isolated from *T. patula* flower petals (Rao and Seshadri 1941).

Flavonoids patulitrin (patuletin 7-*O*-glucoside), patuletin, quercetagenin, quercetagenin 7-*O*-glucoside, luteolin (Bhardwaj et al. 1980a), allopatuletin

(3,6,7,3',4'-pentahydroxy-5-methoxyflavone) a quercetagenin monomethyl ether (Bhardwaj et al. 1980a, b), and kaempferol and quercetin-like structures (Ivancheva and Zdravoka 1993) (patulitrin (patuletin 7-*O*-glucoside), patuletin, quercetagenin 7-*O*-glucoside) and several unknown minor flavonoids (Guinot et al. 2008) (pateletin, patulitrin, patuletin cinnamate derivative, patuletin benzoate derivative (Faizi et al. 2008)) were isolated from the flowers. From the polar extract and fractions of yellow flowers of *Tagetes patula*, phenolic compounds (flavonoids and phenolic acids) were isolated (Faizi et al. 2011b). In the nonpolar extract, a few fatty acids, their methyl esters and thiophenes (including α -terthienyl) were detected. Patuletin, patulitrin and methyl protocatechuate were isolated from the flowers (Faizi et al. 2011a).

Thiophene derivatives were found in *T. patula* cv. Carmen flowers in solvent distillate (SE): 5-(3-buten-1-ynyl)-2,2'-bithienyl (BBT) (3.6 %); 5'-methyl-5-(3-buten-1-ynyl)-2,2'-bithienyl (MeBBT) (nd=not detected); 5-(1-pentynyl)-2,2'-bithienyl (PBT) (50 %); 5-(4-hydroxy-1-butynyl)-2,2'-bithienyl (BBTOH) (nd); 2,2',5',2''-terthienyl (α -T) (34.8 %); 5-(4-acetoxybutynyl)-2,2'-bithienyl (BBTOAc) (11.6 %); 5-methylaceto-5'-(3-buten-1-ynyl)-2,2'-bithienyl (AcOCH₂BBT) (nd); and 5-(3,4-diacetoxy-1-butynyl)-2,2'-bithienyl (BBT(OAc)₂) (nd) (Margl et al. 2002).

Of the 22 constituents identified in the hydro-distilled oil of *T. patula* capitula, grown in Lucknow, 9 were monoterpene hydrocarbons (49.4 %), 3 sesquiterpene hydrocarbons (8.5 %) and 10 oxygenated monoterpenes (32.0 %) (Garg et al. 1999a, b). The major constituents were limonene (24.5 %), terpinolene (12.1 %), (*Z*)- β -ocimene (10.4 %) and (*E*)- and (*Z*)-tagetone (9.3 %). Krishna et al. (2002) found the main constituents of the hydrodistilled oil of the capitula were (*Z*)- β -ocimene (19.9 %), (*Z*)-tagetone (12.4 %), (*E*)-tagetone (10.4 %), piperitenone (5.8 %) and β -caryophyllene (15.1 %). In the essential oil of *T. patula* flowers grown in Venezuela, 21 compounds were identified, and α -terthienyl (43.1 %), pentatriacontane (23.9 %) and 2-ethyl-1-dodecanol (7.9 %) were the major constituents (Martínez et al. 2009).

Flowers had significantly less volatile oil and hairy root cultures produced significantly more volatile oil than intact roots (Szarka et al. 2006). The capitula oil was rich in sesquiterpene β -caryophyllene (53.5 %); other sesquiterpenes included caryophyllene oxide (4.1 %), β -cubebene (3.5 %), spathulenol (0.9 %), traces of (*E*)- β -farnesene and α -humulene; monoterpenes (*z*)-tagetone (4.2 %), (*Z*)- β -ocimene (3.8 %), terpinolene (3.3 %), (*E*)-tagetone (1.9 %), piperitenone (1.6 %), piperitone (0.7 %), (*Z*)-tagetone (0.6 %), (*E*)-tagetone (0.6 %), piperitenone oxide (0.3 %) and limonene trace; and thiophenes 5-(3-penten-1-ynyl)-2,2'-bithienyl (PBT) (5.1 %), α -terthienyl (2.4 %) and BBT (0.8 %) BBTOAc (trace). Thirty compounds were identified in the capitula essential oil, representing 89.1 % of the total detected (Romagnoli et al. 2005). The main components were piperitone (24.74 %), piperitenone (22.93 %), terpinolene (7.8 %), dihydrotagetone (4.91 %), *cis*-tagetone (4.62 %), limonene (4.52 %) and *allo*-ocimene (3.66 %). Other minor compounds included α -terpineol (2.46 %), caryophyllene (2.09 %), *cis*-ocimene (1.8 %), 4-terpineol (1.4 %), 2-phenyl ethyl acetate (1.29 %), *trans*-tagetone (1.13 %), linalool (0.7 %), caryophyllene oxide (0.67 %), *trans*-ocimene (0.61 %), sabinene (0.43 %), 3-hexen-1-ol (0.4 %), spathulenol (0.39 %), isoborneol (0.35 %), germacrene D (0.34 %), *trans*-nerolidol (0.32 %), δ -cadinene (0.31 %), bornyl acetate (0.22 %), *p*-cymene (0.22 %), β -bisabolene (0.2 %), α -pinene (0.18 %), α -phellandrene (0.15 %), β -mircene (0.13 %) and β -copaene (0.13 %). In another study, leaf oil were richer in monoterpenes (terpinolene (21.1 %), piperitone (11.2 %), (*E*)-tagetone (9.5 %), (*Z*)- β -ocimene (6.9 %), limonene (5.9 %), (*E*)-tagetone (5.8 %), piperitone (4.6 %), (*Z*)-tagetone (4.4 %), (*z*)-tagetone (4.1 %) and piperitenone oxide (2.3 %)), sesquiterpenes (β -caryophyllene (3.5 %), β -cubebene (1.5 %), spathulenol (0.8 %) and caryophyllene oxide (0.7 %)) and thiophenes (α -terthienyl (trace), BBT (trace) and BBTOAc (trace)) (Szarka et al. 2006). In a recent study, the major compounds identified in the essential oil from *T. patula* capitula were (*Z*)- β -ocimene, (*E*)- β -ocimene, terpinolene, (*Z*)-ocimenone, (*E*)-ocimenone

and δ -elemene (Prakash et al. 2012). The SPME-GC-FID analyses of live capitula showed that the volatiles were rich in monoterpenoids in comparison to the plucked capitula. In contrast, the plucked capitula recorded significant increase in sesquiterpenoids in comparison to the living capitula. *T. patula* inflorescence oil was composed mainly of β -caryophyllene (23.7 %), terpinolene (15.6 %) and *cis*- β -ocimene (15.5 %) (Armas et al. 2012).

Fruit/Seed Phytochemicals

Thiophene derivatives found in *T. patula* cv. Carmen fruits (achenes) in solvent extract comprised traces of α -T and BBTOAc (Margl et al. 2002). Phytomelanin is found in the hard, black, resistant layer in the pericarp (Pandey 1998).

Forty constituents were identified in *Tagetes patula* seed oil, comprising 94 % of the total oil (Hassanpouraghdam et al. 2011). Sesquiterpene hydrocarbons (52.7 %) and oxygenated sesquiterpenes (15.8 %) were the main subclasses of volatile oil components followed by monoterpene hydrocarbons (12.6 %). The principal constituents were (*E*)-caryophyllene (44.6 %), caryophyllene oxide (14.8 %), germacrene D (3.8 %), (*Z*)- β -ocimene (3.8 %) and limonene (3.7 %). Oxides (15.7 %) were the predominant group of components with caryophyllene oxide as their main representative. α -Terthienyl (3.8 %) comprised partially large amount in the volatile oil content despite of its polar and less volatile nature.

Leaf/Stem/Aerial Part/Seedling Phytochemicals

An enzyme with high substrate specificity and MW of 67,000, namely, 5-(4-acetoxy-1-butynyl)-2,2'-bithiophene, acetate esterase, was partly purified from the aerial parts of *Tagetes patula* (Sütfeld and Towers 1982); 3,4-diacetoxybutynylbithiophene was also detected (Pensl and Sütfeld 1985). Thiophene derivatives were found in *T. patula* cv. Carmen shoots: (3-buten-1-ynyl)-2,2'-bithienyl (BBT), trace from steam distillate

(SD) and 7.9 % from solvent extract (SE)); 5'-methyl-5-(3-buten-1-ynyl)-2,2'-bithienyl (MeBBT), (nd SE, trace SD; 5-(1-pentynyl)-2,2'-bithienyl (PBT) (13.7 SE; 46.4 % SD); 5-(4-hydroxy-1-butyryl)-2,2'-bithienyl (BBTOH) (nd SE; nd SD); 2,2',5,2''-terthienyl (α -T) (nd% SE, 31.8 % SD); 5-(4-acetoxy-1-butyryl)-2,2'-bithienyl (BBTOAc) (12 %SE, 11.6 % SD); 5-methylaceto-5'-(3-buten-1-ynyl)-2,2'-bithienyl (AcOCH₂BBT) (tr SE; nd SD); 5-(3,4-diacetoxy-1-butyryl)-2,2'-bithienyl (BBT(OAc)₂) (nd SE, nd SD) (Margl et al. 2002). A benzofuran, isoeuparin, was isolated from the seedling (Burke et al. 1986).

T. patula seedlings were found to contain four thiophene derivatives: bithienylbutinen, acetoxybutinylbithiophene, hydroxybutinylbithiophene and α -terthiophene in high concentrations (Bohlmann and Zdero 1979; Sütfield and Towers 1982; Sütfield 1982). In *T. patula* seedling, bithienylbutinen, the major thiophene compound in hypocotyls and roots, was found to accumulate earlier than the other thiophene derivatives; acetoxybutinylbithiophene was not found in cotyledons and its synthesis appeared to be light induced, while hydroxybutinylbithiophene was synthesized specifically in the roots, α -terthiophene in the cotyledons (Sütfield 1982).

The essential oil of *T. patula* contained equal amounts of (*Z*)- and (*E*)-ocimenone and also contained limonene and β -caryophyllene (Héthélyi et al. 1986). The hydrodistilled oil of the leaves contained limonene (6.5 %), terpinolene (16.2 %), (*Z*)-tagetone (13.0 %), (*Z*)-tagetenone (5.5 %), (*E*)-tagetenone (8.2 %), piperitone (10.2 %) and piperitenone (12.5 %) as the main constituents (Krishna et al. 2002). The oil of the shoots was found to have limonene (6.8 %), (*Z*)-beta-ocimene (13.7 %), terpinolene (12.0 %), piperitone (5.8 %) and beta-caryophyllene (10.5 %) as the major constituents (Krishna et al. 2002).

The major constituents of the essential oil of the aerial parts were piperitone (33.77 %), *trans*- β -ocimene (14.83 %), terpinolene (13.87 %), β -caryophyllene (9.56 %) and limonene (7.78 %) (Rondon et al. 2006). Minor components included *cis*- β -ocimene (5.01 %), epoxy-ocimene (2.27 %), β -farnesene (1.48 %), germacrene D (1.45 %), bicyclogermacrene (1.52 %), linalool

(0.73 %) and myrcene (0.53 %). The leaf oil was found to have a high content of terpinolene (21.1 %) (Szarka et al. 2006). The following compounds were found in the essential oil of *T. patula* leaves and stems: limonene (37.05 %), terpinolene (32.6 %), piperitone (14.40 %), neophytadiene (5.91 %), sabinene (2.88 %), *trans*-ocimene (2.02 %), β -caryophyllene (1.98 %), farnesol (1.84 %) and α -pinene (1.30 %) (Restello et al. 2009). *T. patula* leaf oil showed terpinolene (20.9 %) and piperitenone (14.0 %) as main components (Armas et al. 2012).

Callus cultures of *T. patula* were found to contain thiophene-biocides, mainly 5-(but-3-en-1-ynyl)-2,2'-bithiophene (BBT) and 5-(4-acetoxy-1-butyryl)-2,2'-bithiophene (BBTOAc) (Ketel 1988). Secondary calli contained about three times higher concentrations of thiophenes than tertiary calli. The occurrence of the major thiophenes (BBTOH, BBT, BBTOAc, α -T) in leaves and roots of *T. patula* (Breteler and Ketel 1993) corresponded with the data of Sütfield (1982).

Root Phytochemicals

Two benzofurans, 4-hydroxydehydroretremetone and hydroxytremetone, were isolated from roots and hypocotyls of seedlings (Sütfield et al. 1985). Bithiophenes 5-(4-acetoxy-1-butenyl)-2,2'-bithiophene and 5-(buten-1-nyl)-2,2'-bithiophene and a benzofuran isoeuparin (5-acetyl-4-hydroxy-2-isopropenylbenzofuran) were isolated from root cultures (Parodi et al. 1988). The benzofurans, isoeuparin and (-)-4-hydroxytremetone were isolated from *T. patula* root cultures (Margl et al. 2005). The benzenoid ring and the acetoxy group were found to be predominantly (>98 %) derived from phenylalanine via 1-deoxy-D-xylulose 5-phosphate pathway. The data indicated that isoeuparin and (-)-4-hydroxytremetone were assembled from 4-hydroxyacetophenone and dimethylallyl diphosphate via prenyl-substituted 4-hydroxyacetophenone and dihydrobenzofurans as intermediates. Root oils were rich in thiophenes (BBT (44 %), α -terthienyl (21.8 %), PBT (0.3 %), BBTOAc (6.1 %)), sesquiterpenes (α -gurjunene (4.3 %), (*E*)- β -farnesene (3.9 %),

β -caryophyllene (0.7 %), β -cubebene (0.6 %) and monoterpene (piperitenone (0.2 %)) (Szarka et al. 2006).

α -Terthienyl was isolated from hairy roots induced by infection with *Agrobacterium rhizogenes* (Kyo et al. 1990). Depending on the hairy root line used, the level of α -terthienyl varied from 15 to 1,268 $\mu\text{g/g}$ dry weight, a level that corresponded to 0.15–12.7-fold that in intact roots. Opines were also detected.

From hairy root cultures, four bithiophenes (5-(3-buten-1-ynyl)-2,2'-bithienyl (BBT), 5-(4-hydroxy-1-butynyl)-2,2'-bithienyl (BBTOH), 5-(4-acetoxy-butynyl)-2,2'-bithienyl (BBTOAc) and 5-(3,4-diacetoxy-1-butynyl)-2,2'-bithienyl (BBT(OAc)₂); stigmaterol, β -farnesene and 3 benzofurans (dehydrotremetone, 14-isobutyryloxyeuparin and 2,3,-dihydro-14-isobutyryloxyeuparin) were isolated (Menelaou et al. 1991). Thiophene production in hairy root cultures of *Tagetes patula* was found to increase with the addition of an elicitor derived from mycelial extracts of *Fusarium congenitans* (Mukundan and Hjortso 1990). The major thiophenes produced were 5-(4-aceoxy-1-butenyl)-2,2'-bithiophene and 5-(buten-1-enyl)-2,2'bithiophene. Rajasekaran et al. (1999) found that treatment of cultured hairy roots with mycelial extract of *Aspergillus niger* (1.5 % v/v) elicited an increase in thiophene content by 1.6-folds over the control. Maximum production of thiophene was recorded at the end of the fourth week in culture with a content of 0.138 % (w/w on dry weight basis). α -Terthienyl was predominant.

Thiophene derivatives were found in *T. patula* cv. Carmen roots: BBT (65 % from steam distillate (SD) and 93.2 % from solvent extract (SE)); PBT (trace SE; nd SD); BBTOH (trace SE; nd SD); α -T (8.5 % SE, 5.2 % SD); BBTOAc (24.7 %SE, 1.6 % SD); AcOCH₂ BBT (tr SE; nd SD); and BBT(OAc)₂ (tr SE, nd SD) (Margl et al. 2002). Two thiophenes, 5'-hydroxymethyl-5-(3-buten-1-ynyl)-2,2'-bithiophene and methyl-5-[4-(3-methyl-1-oxobutoxy)-1-butynyl]-2,2'-bithiophene(2), were isolated from the roots (Bano et al. 2002).

Roots of *Tagetes* species (*T. erecta*, *T. filifolia*, *T. lucida*, *T. minuta*, *T. patula* and *T. tenuifolia*) have the highest diversity and contents of thio-

phenes (from 64 to 100 % of the total thiophene amount), with 5-(3-buten-1-ynyl)-2,2'-bithienyl (BBT) as the main component followed by 5-(4-acetoxy-1-butynyl)-2,2'-bithienyl (BBTOAc), 2,2':5',2''-terthienyl (α -T) and 5-(4-hydroxy-1-butynyl)-2,2'-bithienyl (BBTOH) (Marotti et al. 2010). The SFE (supercritical fluid CO₂) extraction of intact roots and flowers yielded 717 and 480 $\mu\text{g/g}$ 2,2':5',2''-terthiophene (α -T), respectively, while the leaves did not contain considerable amounts of thiophenes (Szarka et al. 2010). Remarkable amounts of thiophene metabolites, 5-(3-buten-1-ynyl)-2,2'-bithienyl (BBT) and 5-(3,4-diacetoxy-1-butynyl)-2,2'-bithienyl [BBT(OAc)₂], were characteristic of the SFE of hairy root cultures. Other compounds identified in the roots included 5-(4-hydroxy-1-butynyl)-2,2'-bithienyl (BBTOH), 2,2':5',2''-terthiophene (α -T), 5-(4-acetoxy-1-butynyl)-2,2'-bithienyl (BBTOAc), α -gurjunene (4.3 %), (*E*)- β -farnesene (3.9 %), β -caryophyllene, β -bisabolene, caryophyllene alcohol, methyl palmitate, palmitic acid and linoleic acid.

Four thiophenes (α -terthienyl (α -T), BBT, BBTOH, BBTOAc) and two benzofurans (euparin and 6-hydroxy-2-isopropenyl-5-acetyl, cumaranon (dihydro-euparin)) were identified in the root exudates collected from the undisturbed rhizosphere of Marigold (*Tagetes patula*) (Tang et al. 1987). Based on the total ion current chromatograms, the ratios of thiophenes in the rhizosphere were 20:25:12:1 for BBT, BBTOH, BBTOAc and α -T, respectively. These ratios were different from those obtained from the ethyl acetate extract of the roots, in which the ratios were 12:0.2:8:1. Dihydroeuparin had been isolated as a major benzofuran from *T. patula* by Bohlmann and Zdero (1979). Citric and malic acids, pyridine hydrochloride and 2-hydroxy, 5-hydroxymethyl furan, were isolated from the methanol root extract (Saleem et al. 2004).

The biosynthesis of 5-(3-buten-1-ynyl)-2,2'-bithiophene was studied in root cultures of *Tagetes patula* (Margl et al. 2001). Their data confirmed the biosynthetic route was via progressive desaturation of long-chain fatty acids precursors to C₁₈ polyacetylenes and the incorporation of a suitable S-source into pentayne (CI3) as proposed by Jente et al. (1981) who used

triated precursors given to soil-grown *Tagetes patula*. However, Margl et al. (2001) stated that a polyketide-like biosynthesis via a carbocyclic intermediate cannot be excluded. The mono-thiophene-2-(but-3-en-1-ynyl)-5-(penta-1,3-diynyl)-thiophene, present in small amounts in *Tagetes patula* hairy roots, was found to be the precursor of all bithienyls that had been described for this species but not of α -terthienyl (Arroo et al. 1995). They found that 5'-methyl-5-(3-buten-1-ynyl)-2,2'-bithienyl was converted into (5'-but-3-en-1-ynyl-[2,2']bithiophenyl-5-yl)-methyl acetate, probably via (5'-but-3-en-1-ynyl-[2,2']bithiophenyl-5-yl)-methanol. Substitution of the butenyl side chain of 5-(3-buten-1-ynyl)-2,2'-bithienyl resulted in the formation of 5-(3,4-dihydroxy-1-butyryl)-2,2'-bithienyl and 5-(4-hydroxy-1-butyryl)-2,2'-bithienyl, which were subsequently converted into, respectively, 5-(3,4-diacetoxy-1-butyryl)-2,2'-bithienyl and 5-(4-acetoxy-1-butyryl)-2,2'-bithienyl. The end products of this biosynthetic pathway were all bithienyl-acetate esters.

Antioxidant Activity

Of three Indian Marigold (*Tagetes patula*) cultivars, the Marigold orange (MGO) variety was found to contain the maximum amount of lutein (Bhattacharyya et al. 2010). It also had the highest DPPH radical scavenging activity and ABTS radical scavenging activity, with an EC_{50} value of 0.344 mg/ml. It was also the most effective against lipid peroxidation and hydroxyl radical scavenging activities. The MGO extract also had the maximum reducing power. Hepatic cell damage in iron-mediated Fenton reaction caused by free radicals was reduced by the Marigold extracts. The results suggested that Marigold flowers of Indian variety can be effectively utilized to produce lutein ester, which could be used as a food supplement or as an accessible source of natural antioxidants. Polar extracts, fractions and phases of the flowers demonstrated better antioxidant activity (Faizi et al. 2011a). Of the isolated constituents, methyl protocatechuate showed IC_{50} value of 2.8 μ g/ml, whereas patuletin (IC_{50} =4.3 μ g/ml) was comparable to

quercetin and rutin but significantly better than patulitrin (IC_{50} =10.17 μ g/ml). Toxicity test for the methanol extract and compound 2 did not elicit any behavioural changes or cause mortality in mice.

Antimicrobial Activity

Alpha-terthienyl (α T), a thiophene compound isolated from *Tagetes patula* (Asteraceae), exhibited antifungal activity towards five strains of dermatophytes (*Trichophyton mentagrophytes*, *T. rubrum*, *T. violaceum*, *Epidermophyton floccosum*, *Microsporum cookei*) (Romagnoli et al. 1994). α -T plus UVA irradiation for 90 minutes acted as a fungistatic at concentrations between 6 and 24 μ M. Between 1 and 10 days after irradiation, the fungal growth was reduced or arrested with marked responses for *T. mentagrophytes*, *T. rubrum* and *M. cookei*. After UVA irradiation the photoactive compound caused damage to membranes of the nucleus, mitochondria and endoplasmic reticulum. Plasmolytic and autolytic changes resulted in plasma membrane breakage and in cell wall aberrations. 5-(4-hydroxy-1-butyryl)-2,2'-bithienyl (BBTOH), the thiophene from the roots, was found to be biocidal to *Fusarium oxysporum* (Arroo et al. 1995).

The essential oil of the aerial parts of *Tagetes patula* showed strong antibacterial activity against important human pathogenic with MIC values for *Staphylococcus aureus* (30 μ g/ml), *Enterococcus faecalis* (30 μ g/ml), *Escherichia coli* (60 μ g/ml), *Klebsiella pneumoniae* (90 μ g/ml) and *Pseudomonas aeruginosa* (130 μ g/ml) (Rondon et al. 2006). The hot aqueous extracts of *Tagetes patula* exerted higher antibacterial activity as compare to cold aqueous extract and methanol extract at 40 mg/ml concentration (Jain et al. 2012). It was highly inhibitory towards *Proteus vulgaris*, moderately towards *Aeromonas sobria*, *Aeromonas hydrophila*, *Staphylococcus aureus* (MTCC7405) and *Bacillus subtilis* but least so against *Staphylococcus aureus* (clinical isolate). Minimal inhibitory concentrations (MICs) were between concentrations of 20–160 mg/ml with both aqueous or methanol extracts. The methanol flower was found to possess antimicrobial activ-

ity, and its principal flavonoid patuletin was isolated as the active antibacterial principle with minimum inhibitory concentration (MIC) value of 12.5 µg/disc against *Corynebacterium* spp., *Staphylococcus* spp., *Streptococcus* spp. and *Micrococcus luteus* (Faizi et al. 2008). Its glucoside, patulitrin (4), was found to be weakly active, except against *Staphylococcus saprophyticus*, *Streptococcus faecalis* and *Streptococcus pyogenes*. The patuletin cinnamate derivative displayed antibacterial activity comparable with the parent flavonoid with a MIC value of 50 µg/disc against *Corynebacterium* spp., whereas patuletin benzoate derivative was found to be devoid of any antibacterial activity.

Two intensely mauve UV fluorescent compounds 5-(3-buten-1-ynyl)-2,2'-bithienyl and α-terthienyl isolated from *Tagetes patula* roots were found to be phototoxic to *Candida albicans* (Chan et al. 1975). The UV-mediated antibiotic activity of polyacetylenes and their thiophene derivatives from *Tagetes* species with their phototoxic effects on *Candida albicans* and certain pathogenic microorganisms and their apparent lack of phototoxicity towards the skin (except for alpha-terthienyl) suggested a potential topical therapeutic role for them in yeast, fungal and bacterial infections and light-responsive dermatoses (Towers et al. 1979).

Antiinflammatory Activity

The methanol extract of *Tagetes patula* florets inhibited acute and chronic inflammation in mice and rats when administered orally (Kasahara et al. 2002). The extract significantly suppressed hind-paw oedema induced by gamma-carrageenan in mice. Further, the extract not only inhibited the hind-paw oedema induced by various acute phlogogens, such as histamine, serotonin, bradykinin and prostaglandin E1, but also suppressed the increase of vascular permeability by acetic acid, indicating that it primarily acted at the exudative stage of inflammation. In the chronic inflammation model, the extract did not inhibit the proliferation of granulation tissue when tested by the cotton pellet method; however, it was effective on the development of adjuvant arthritis in rats.

Podiatric Therapeutic Activity

In a double-blind placebo-controlled trial carried out for 8 weeks, involving patients with bilateral hallux abducto valgus and its associated condition, bunion, administration of *T. patula* preparations, plus protective pad, was effective in reducing the width of the lesion and level of pain of hallux abducto valgus (Khan 1996).

Analgesic Activity

Patuletin, isolated from the flower, demonstrated mild analgesic activity in the acetic acid-induced writhing test and hot-plate test in mice (Faizi et al. 2011a).

Hypotensive Activity

Citric and malic acids isolated from the methanol root extract caused 71 and 43 % fall in mean arterial blood pressure (MABP) of rats at the doses of 15 and 30 mg/kg, respectively (Saleem et al. 2004). LD₅₀ and LD₁₀₀ of citric acid had been determined as 545 and 1,000 mg/kg, respectively.

Hypertensive Activity

Pyridine hydrochloride isolated from the methanol root extract produced 34 % rise in the mean arterial blood pressure of rats at the dose of 30 mg/kg (Saleem et al. 2004).

Anticataract Activity

Patulin extracted from *Tagetes patula* inhibited aldose reductase of Wistar rat lens by 100 % at 10⁻¹ M, 780.0 % at 10⁻⁵ M and 22.7 % at 10⁻⁶ M (Li et al. 1991).

Acaricidal Activity

A 70 % ethanol extract from aerial parts of *T. patula* exhibited acaricidal activity against

Rhipicephalus sanguineus, the thick involved in the transmission of pathogens such as *Babesia canis*, *Ehrlichia canis*, *Coxiella burnetii*, *Rickettsia rickettsii* and *Rickettsia conorii* (Politi et al. 2012). At 50.0 mg/ml, the extract decreased oviposition rate by 21.5 % and eliminated 99.78 % of the larvae. Also it was determined that the best results were obtained with 5 minutes of immersion.

Larvicidal Activity

The thiophenes produced in callus cultures of *T. patula* showed larvicidal effect against mosquito larvae (Rajasekaran et al. 2003). *Tagetes patula* essential oil exhibited larvicidal activity against the fourth instar larvae of *Aedes aegypti*, *Anopheles stephensi* and *Culex quinquefasciatus* (Dharmagadda et al. 2005). *A. aegypti* (LC₅₀ 13.57, LC₉₀ 37.91) was most susceptible followed by *An. stephensi* (LC₅₀ 12.08, LC₉₀ 57.62) and *C. quinquefasciatus* (LC₅₀ 22.33, LC₉₀ 71.89).

Toxicity Studies

The essential oils of *Tagetes* flowers were tested for their toxicological potential on mice; the results showed that the oils had a low toxicity with a TD₅₀ 99.6 mg/kg for *T. erecta* and 112 mg/kg for *T. patula* (Martínez et al. 2009).

Allergic Dermatitis Problem

Topically applied alpha-terthienyl evoked biphasic phototoxic dermatitis and the appearance of 'sunburn' cells in human epidermis (Towers et al. 1979). None of 11 polyacetylenes had the same effect although they mimicked alpha-terthienyl in their phototoxic effects on *Candida albicans* and certain pathogenic microorganisms. Bilsland and Strong (1990) reported a case of allergic contact dermatitis from the essential oil of French Marigold (*Tagetes patula*) in an aromatherapist.

Traditional Medicinal Uses

The whole herb is aromatic, digestive, diuretic and sedative (Bown 1995). It is used internally in the treatment of indigestion, colic, severe constipation and to treat sore eyes.

In the Philippines, a flower decoction is taken internally as a carminative and used as a refreshing drink (Guerrero 1921). In Argentina, the plant extract is taken internally as a calmate and diuretic; a plant decoction is taken internally as a stimulant and stomachic (stomach strengthener) (Neher 1968). In Columbia and in Venezuela, the plant infusion is used as a bath or rub for rheumatism (Neher 1968).

Other Uses

T. patula is a popular ornamental plant especially in temperate and subtropical areas around the world. In Argentina, the plant is used as a forage crop for sheep and goat but not cattle (Neher 1968). *T. patula* produces a significant amount of essential oil, which has characteristic antibacterial, antifungal and insecticide effects (Szarka et al. 2006). The 'Genda Attar' perfume has a beautiful and refreshing fragrance and is made from Marigold essential oil and sandalwood oil. Marigold flower garlands are used for adornment during Indian marriage ceremonies and on other special ceremonies.

Studies showed that *T. patula* essential oil (aerial parts) at concentration of 10 µl effectively control the stored grain pest, *Sitophilus zeamais* adults (Restello et al. 2009). The capitula essential oil exerted a good antifungal activity against two phytopathogenic fungi, *Botrytis cinerea* and *Penicillium digitatum*, providing complete growth inhibition at 10 and 1.25 µl/ml, respectively (Romagnoli et al. 2005). The two main compounds, piperitone and piperitenone, caused large alterations in hyphal morphology and a multisite mechanism of action. Methanol *Tagetes patula* plant extract exhibited antifungal activity against three phytopathogenic fungi: *Botrytis cinerea*, *Fusarium moniliforme* and *Pythium ultimum* (Mares et al. 2002, 2004). The extract proved to

have a dose-dependent activity on all the fungi with a marked difference between treatments in the light than in the dark. The presence of a luminous source enhanced the antifungal activity, with small differences between UVA and solar spectrum light. *Tagetes patula* extract induced alterations on *Pythium ultimum* cell membranes.

The plant contains polyacetylenic thiophenes in their roots that confer strong biocidal activity, useful for suppressing nematode populations in the soil and as sources of safe and natural pesticides (Marotti et al. 2010). *T. erecta* and *T. patula* were employed as a cover crop in Indian tea plantations to suppress nematodes (Neher 1968). Greenhouse studies by Ploeg (1999) demonstrated that preplanting of Marigold cultivars of *Tagetes patula*, *T. erecta*, *T. signata* and a *Tagetes* hybrid all reduced galling and numbers of second-stage juveniles of *Meloidogyne incognita*, *M. javanica*, *M. arenaria* and *M. hapla* in subsequent tomato plantings. Field studies found that *T. patula* diminished *Pratylenchus penetrans* populations in strawberries (Evenhuis et al. 2004). The effect of *T. patula* on *P. penetrans* population densities lasted longer than the effect of chemical soil fumigation. Strawberries were grown for 3 consecutive years after *T. patula* without damage by the root lesion nematode.

The polar extract and fractions of yellow flowers of *Tagetes patula* showing nematocidal activity against cyst nematode *Heterodera zae* led to the isolation of phenolic compounds (flavonoids and phenolic acids). In the nonpolar extract, a few fatty acids, their methyl esters and thiophenes (including α -terthienyl) were detected. In studies of compounds obtained commercially, α -terthienyl and gallic and linoleic acids showed 100 % mortality at concentrations of 0.125 % after 24 hours. *N*-hexane extract of the roots showed nematocidal activity against *Pratylenchus penetrans* which was due predominantly to α -terthienyl (Kyo et al. 1990). Studies found that population levels of root-lesion nematode (*Pratylenchus penetrans*) were consistently lower under Marigolds (*Tagetes tenuifolia* cv. Nemakill and cv. Nemanon, *T. patula* ssp. *nana* unidentified cv. and *T. erecta* cv. Crackerjack) compared to the other cover crops tested

(Kimpinski et al. 2000). Correspondingly, average potato tuber yields were significantly higher (8–14 %) when potato followed Marigolds.

Comments

Cytological and morphological evidence indicated that *Tagetes patula* L. to be an allotetraploid species ($2n=48$) which probably originated by hybridization between the diploids *T. erecta* L. and *T. tenuifolia* Cav., or species closely related to them (Towner 1961).

Tagetes tenuifolia

Scientific Name

Tagetes tenuifolia Cav.

Synonyms

Tagetes jaliscensis var. *minor* Green., *Tagetes macroglossa* Pol., *Tagetes oligocephala* DC., *Tagetes peduncularis* Cav.

Family

Asteraceae

Common/English Names

American Saffron, Lemon Marigold, Lemon Gem, Orange Gem, Signet Marigold, Striped Mexican Marigold, Slender Leaf Marigold, French Marigold

Vernacular Names

Danish: Gem Tagetes, Smalfliget Fløjlsblomst, Tangerine
Eastonian: Ahtalehine Peiulill
Finnish: Kääpiösamettikukka
French: Tagète Maculé, Tagète Taché

German: Feinblatt-Studentenblume, Gestreifte Mexikanische Studentenblume, Schmalblatt-Studentenblume

Polish: Aksamitka Wąskolistna

Slovaščina: Tankolistna Žametnica, Žametnica Tankolistna

Swedish: Litet Sammetsblomster, Liten Tagetes

Origin/Distribution

T. tenuifolia is native to Central America—Mexico, Nicaragua, Guatemala, Costa Rica Honduras, El Salvador and Panama—and is cultivated elsewhere.

Agroecology

T. tenuifolia has similar climatic requirements as other *Tagetes* species. The plant is adaptable to heavy clay and sandy soils but grows best in well-drained, fertile soil rich in organic matter and in full sun.

Edible Plant Parts and Uses

The flowers are edible and have a pleasant lemon-like flavour and can be used sparingly as a flavouring in salads, sandwiches, potato soups, wines, etc. or used as a garnish (Facciola 1990). The foliage of the signet Marigold also has a pleasant lemon fragrance.

Botany

A small, annual, erect, branched herb, 30–50 cm high. Stem bluntly quadrangular, furrowed smooth, purplish at the basal parts. Leaves, opposite, pinnately dissected green, smooth, glossy leaves (Plate 1). Leaflets numerous, opposite to alternate, lanceolate, serrate, tip acute with a long arista and gland dotted. Flowers terminal or axillary, bright yellow, peduncle leafy generally 3 flowered, quadrangular and furrowed (Plate 1). Involucre tubular, clavate, 5 angular, 5-toothed with acute teeth, smooth. Receptacle convex, gland dotted, Ray florets 5 large, obcordate, spreading flat with style and bifid stigma, no stamens. Disc florets, numerous, tubular, 5-cleft with stamens and style, strongly 5-nerved alternating with segments, stamens 5 inserted in tube, anthers connected in tube, filament smooth, style exerted above stamens, stigma bifid. Seed linear, flat, rough, pubescent with pappus consisting of 2 paleaceous scales.

Nutritive/Medicinal Properties

The major constituents of *T. tenuifolia* essential oil were dihydrotagetone, tagetone and (*E*)-ocimenone and also contained small amounts of (*Z*)-ocimenone (Héthyly et al. 1986).

The maximum amount of xanthophylls accumulated in the flowers with orange (or orange

with claret spots) petals, where the content of carotenoids (recalculated for lutein) exceeded 5 mg per gram of fresh petals against 1 mg/g for yellow and 0.2 mg/g for lemon-yellow flowers (Deineka et al. 2007). The Marigold flowers of orange colour with claret spots were characterized by a high content of anthocyanins. The main component was cyanidin-3-glucoside; some samples also contained a significant amount (10–50 %) of another cyanidin derivative identical to that of cyanidin-3-glucoside acylated with malonic acid. The main acids of isolated lutein diester esters were myristic and palmitic acids (accounting for 85–90 % of the total sum of acid radicals); smaller fractions represented stearic and lauric acid radicals.

T. tenuifolia was reported to contain the flavonoid, isorhamnetin *O*-diglycoside (De Israilev and Seeligmann 1983); quercetin 3-*O*-arabinoside, quercetin 3-*O*-galactoside and isorhamnetin 3,7-Di-*O*-galactoside (De Israilev and Seeligmann 1994); and quercetagetin, kaempferol, kaempferitrin, quercetin, quercetin-3-*O*-glucoside, quercetin-3-*O*-rhamnoside (Abdala 2001) and α -terthienyl (Vasudevan et al. 1997). *T. tenuifolia* and *T. minuta* seedlings were found to contain 5-(4-hydroxy-1-butynyl)-2,2'-bithienyl (BBTOH); 5-(4-acetoxy-1-butynyl)-2,2'-bithienyl (BBTOAc), while *T. campanulata* Griseb and *T. laxa* Cabrera seedlings also accumulated BBT and alpha-T (Talou et al. 1994). From the four *Tagetes* species tested, only *T. laxa* was able to produce transformed roots when infected with *Agrobacterium rhizogenes* LBA 9402. Several clones of transformed roots were obtained in which the total thiophene content present showed considerable variations (277–1,773 $\mu\text{g/g}$ FW).

Roots of *Tagetes* species (*T. erecta*, *T. filifolia*, *T. lucida*, *T. minuta*, *T. patula* and *T. tenuifolia*) were found to have the highest diversity and contents of thiophenes (from 64 to 100 % of the total thiophene amount), with 5-(3-buten-1-ynyl)-2,2'-bithienyl (BBT) as the main component followed by 5-(4-acetoxy-1-butynyl)-2,2'-bithienyl (BBTOAc), 2,2':5',2''-terthienyl (α -T) and 5-(4-hydroxy-1-butynyl)-2,2'-bithienyl (BBTOH) (Marotti et al. 2010). *Tagetes lucida* and *T. tenuifolia* possessed the highest amounts

Plate 1 Flowers and foliage

of total thiophenes (6717.3 and 6452.5 mg/kg dry weight, respectively), while *T. minuta* had the highest total thiophene yield (518.8 mg/m²), with BBT accounting for 98 % of the total.

Traditional Medicinal Uses

In Mexico, a decoction of the entire plant is taken internally for snakebite, while a leaf poultice is used for bruises and contusions in Peru (Neher 1968).

Other Uses

Lemon Marigold is a popular ornamental bedding and pot plant. Secretions from the plant roots have an insecticidal effect on the soil, effective against nematodes and to some extent against keeled slugs; they also have an effect against some persistent weeds such as couch grass (Philbrick and Gregg 1966; Huxley et al. 1992). The plant also has an effect on asparagus beetle and bean weevils. A yellow dye is obtained from the flowers (Buchanan 1999).

The plant contains polyacetylenic thiopenes which possess strong biocidal activity, useful for suppressing nematode populations in the soil and as sources of safe and natural pesticides (Marotti et al. 2010). The root exudate of *T. tenuifolia* was found most toxic to the plant nematodes *Rotylenchulus reniformis* followed by *Tylenchorhynchus brassicae* and *Meloidogyne incognita* (Siddiqui and Alam 1988). Studies found that population levels of root-lesion nematode *Pratylenchus penetrans* were consistently lower under Marigolds (including two Marigold cultivars, *Tagetes tenuifolia* cv. Nemakill and cv. Nemanon, *T. patula* ssp. *nana*, unidentified cv. and *T. erecta* cv. Crackerjack) compared to the other cover crops tested (Kimpinski et al. 2000). Correspondingly, average potato tuber yields were significantly higher (8–14 %) when potato followed Marigolds. Another study found Marigold species and cultivars to differ in their magnitude of suppression of the root-knot nematode, *Meloidogyne incognita* (Ploeg and Maris 1999). *T. tenuifolia* cv. Tangerine Gem and

the *Tagetes* hybrid Polynema allowed reproduction and root galling when grown at 30 °C and should not be used for control of *M. incognita* at temperatures close to 30 °C.

Comments

most of Europe and the Mediterranean area, also in North America and Chile in South America. Feverfew is now grown in North and South America, Europe, North Africa, China, Japan and Australia.

Agroecology

A cool climate species, feverfew occurs in mountain scrub, rocky slopes, fields, grassland, riverbeds, forest edges, along roadsides, stream banks, disturbed sites, waste places, urban sites and even walls from 10 to 2,500 m altitude. It thrives in full sun or shade (40–80 %). It occurs as a weed in gardens, yards and rubbish tips.

Edible Plant Parts and Uses

Flowers are edible and dried flowers are used as herbal tea, in wine and in certain pastries (Uphof 1968; Facciola 1990; Rop et al. 2012). The plant is used in cooking to impart a deliciously aromatic bitter taste to certain foods (Chiej 1984).

Studies found that an extraction temperature of 80 °C was optimum to provide aqueous extracts rich in parthenolide content and phenolic content and, with a desirable colour, suitable for incorporation into a functional beverage (Marete et al. 2009).

Botany

A perennial or annual, pungent, aromatic erect herb, 20–50 (–70 cm) high with numerous puberulous, grooved, terete stem branching from a rootstock with fibrous roots. Leaves alternate, radical or cauline, punctate glandular on both surfaces, lime-green, glabrous or weakly pubescent on 2.5–8 cm long petioles; upper leaves smaller and sessile to subsessile. Lamina ovate-oblong, 2–8 cm × 1.5–5 cm, bipinnate or pinnatifid into obtuse-subacute ultimate segments. Capitula radiate, heterogamous, few to several on 2.5–3.5 cm peduncle, formed in terminal dense corymbs. Involucre hemispherical, 3-seriate phyllaries imbricate, finely pubescent, green,

Origin/Distribution

Feverfew is indigenous to Eurasia—Balkan Peninsula in Southeastern Europe, Anatolia and the Caucasus. It is adventive by introduction in

Plate 1 Feverfew flowers (Louis M Landry)

outer lanceolate, inner oblong-oblongeolate, weakly pubescent to glabrescent. Receptacle convex of flattish. Ray florets, 5–12, female, with oblong, obtusely-3-lobed white ligules (Plate 1). Disc florets, numerous, yellow, tubular-infundibuliform with 5-toothed corolla tube, ovary of 2 fused carpels, stamens 5. Cypsels oblong, greyish brown, 1–1.5 mm, with 6–8 white ridges and sessile glands. Pappus membranous, coroniform with irregular lobes.

Nutritive/Medicinal Properties

Flower Phytochemicals

Rop et al. (2012) reported that edible flowers of *Chrysanthemum parthenium* (*Tanacetum parthenium*) had a dry matter content (%w/w) of 9.86 %, crude protein of 6.77 g/kg and the following elements (mg/kg fresh mass (FM)): P 501.29 mg, K 3600.34 mg, Ca 341.32 mg, Mg 159.17 mg, Na 113.31 mg, Fe 5.83 mg, Mn 7.33 mg, Cu 2.35 mg, Zn 5.94 mg and Mo 0.31 mg. The flowers had total antioxidant capacity of 4.21 g ascorbic acid equivalents/kg FM, total phenolic content of 2.72 g gallic acid/kg FM and total flavonoid content of 1.29 g rutin/kg FM. Flowers of field-grown plants had higher concentration of parthenolide (3.8 % w/w dw) than those from hydroponic plants (1.2 % w/w dw) (Pedneault et al. 2002). A hydroalcohol solution was found to extract more melatonin from the

flowers than the hot water extract (Ansari et al. 2010).

The oil yield obtained by SFE (supercritical fluid extraction) of feverfew-flowering heads was similar to that resulting from hexane extraction (5.4 and 4.92 %, respectively) (Kery et al. 1999). The yield of essential oil obtained by steam distillation was only approximately one tenth that obtained by SFE or hexane extraction. Chemical analysis of the volatile constituents of feverfew revealed the presence of 17 major components, 13 of which were identified. The main constituents of each product were camphor and chrysanthenyl acetate. Other minor volatile components identified were α -pinene, camphene, β -pinene, limonene, *p*-cymene, eucalyptol, γ -terpinene, linalool, α -thujone, borneol and α -terpineol.

The essential oil contents of *T. parthenium* based on the dry weight of wild and cultivated plants from Iran were 0.1 and 0.4 % (w/w), respectively (Mirjalili et al. 2007). In total, 33 and 30 constituents were identified and quantified in wild and cultivated samples, representing 95.7 and 97.5 % of the total oil, respectively. In the oil of the wild sample, camphor (50.5 %), germacrene-D (9.2 %), camphene (7.7 %), (*E*)-sesquilavandulol (4.8 %) and (*E*)-myrtanol (4.7 %) were the major compounds; the minor components were tricylene (1.1 %), α -pinene (0.5 %), dihydrosabinene (0.2 %), sabinene (0.2 %), β -pinene (0.4 %), α -phellandrene (0.1 %), *p*-cymene (0.5 %), limonene (0.5 %), γ -terpinene (0.4 %), filifolone (1.4 %), chrysanthenone (1.3 %), pinocarvone (tr), borneol (0.6 %), 4-terpineol (0.5 %), lavandulyl acetate (0.1 %), bornyl acetate (1.5 %), α -capaene (0.3 %), β -elemene (0.1 %), (*E*)-caryophyllene (0.3 %), (*Z*)- β -farnesene (2.1 %), γ -gurjunene (0.1 %), (*Z,E*)- α -farnesene (1.5 %), bicyclogermacrene (1.1 %), δ -cadinene (0.2 %), spathulenol (0.4 %), viridiflorol (0.6 %), α -cadinol (1.5 %), valeraron (0.1 %) and (*Z*)-nucliferol acetate (1.2 %). In the oil of cultivated plant, the major components were camphor (57.6 %), (*E*)-chrysanthenyl acetate (25.1 %), camphene (4.6 %) and bornyl angelate (2.2 %); the minor components were tricylene (0.2 %), α -pinene (0.3 %), sabinene (tr), β -pinene (tr), *p*-cymene (1.1 %), limonene (0.3 %), γ -terpinene (0.3 %),

terpinolene (tr), linalool (0.2 %), α -campholenal (0.4 %), α -cyclocitral (0.1 %), pinocarvone (tr), borneol (0.5 %), 4-terpineol (0.5 %), α -terpineol (tr), (*E*)-carveol (tr), bornyl acetate (1.4 %), neryl acetate (tr), β -terpinyl acetate (0.1 %), α -copaene (tr), (*E*)-caryophyllene (0.5 %), (*Z*)- β -farnesene (1.2 %), germacrene D (0.2 %), bornyl angelate (2.2 %), caryophyllene oxide (0.4 %), viridiflorol (0.1 %) and α -cadinol (0.2 %). It was found that (*E*)-chrysanthenyl acetate and bornyl angelate were only observed in the oil of the cultivated sample, and (*E*)-sesquilavandulol (4.8 %) and (*E*)-myrtenol (4.7 %) were completely absent in the oil of this sample. Oxygenated monoterpenes predominated in the oil of cultivated (85.9 %) and wild (60.6 %) samples. The oil of wild plants contained primarily of ten monoterpene hydrocarbons (11.6 %), nine oxygenated monoterpenes (60.6 %), eight sesquiterpene hydrocarbons (14.9 %) and six oxygenated sesquiterpenes (8.6 %), while the oil of cultivated plants consisted mainly of nine monoterpene hydrocarbons (6.8 %), 13 oxygenated monoterpenes (85.9 %), four sesquiterpene hydrocarbons (1.9 %) and four oxygenated sesquiterpenes (2.9 %).

Thirty compounds were identified in the flower-head essential oil, and the major compounds were camphor 48.4 %, chrysanthenyl acetate 26.3 % and camphene 8.76 % (Rateb et al. 2007). Other minor components included *cis*-2-octene, butyl acetate, tricylene, α -pinene, camphene, sabinene, β -pinene, *p*-cymene, limonene, 1,8-cineole, γ -terpinene, *p*-cymenene, borneol, terpin-4-ol, α -terpineol, linalool acetate, thymol, *E*-pinocarvyl acetate, *E*-caryophyllene, germacrene D, germacrene D-4-ol, *Z*-chrysanthenyl angelate, bornyl angelate, β -caryophyllene oxide, globulol, *E,E*-farnesol and *E,E*-farnesyl acetate.

Seed Phytochemicals

Seeds were found to be rich in parthenolide and to contain tanaparthin- α -peroxide (Kaplan et al. 2002). Majdi et al. (2011) found that the highest expression of germacrene A synthase (*TpGAS*) was in glandular trichomes which also contained

the highest concentration of parthenolide, suggesting that glandular trichomes were the secretory tissues where parthenolide biosynthesis and accumulation occurred. Expressions of (*E*)- β -caryophyllene synthase (*TpCarS*), amorpha-4,11-diene synthase, were also observed.

Aerial Parts/Plant Phytochemicals

Three pinene derivatives, two spiroketal enol ether polyines, four germacranolides and six guaianolides, two of them being endoperoxides and two secoguaianolides, were isolated from the aerial parts: germacranolide—parthenolide; eudesmolides reynosin and santamarin; guaianolides canin and artecanin; and non-lactone terpenes including camphor, β -farnesene and germacrene D, chrysanthenyl acetate, bornyl acetate, bornyl angelate, α -pinene derivatives and spiroketal enol ether polyines (Bohlmann and Zdero 1982). Compounds isolated from feverfew included sesquiterpene lactones, parthenolide, 3- β -hydroxy parthenolide, secotanapartholide A, canin and artecanin (Groenewegen et al. 1986); guaianolides, tanaparthin- α -peroxide, canin and secotanapartholide-A [major group] and the corresponding 'β' series [β -peroxide, artecanin and the *seco*-B derivative] (Begley et al. 1989); significant amounts of parthenolide, camphor and chrysanthenol acetate (Smith and Burford 1992); guaianolide 3,4-epoxy-8-deoxycumambrin B and the eudesmanolide epoxysantamarine (Milbrodt et al. 1997); flavonoids, 3,6,4'-trimethyl ether and quercetagenin 3,6,3'-trimethyl ether, methyl ethers of scutellarein and 6-hydroxyluteolin, chrysoeriol 7-glucuronide, quercetin 7-glucuronide and apigenin and luteolin 7-glucuronides (Williams et al. 1999a); (2-glyceryl)-*O*-coniferaldehyde as the major constituent of *T. parthenium* tissue culture (Laiking and Brown 1999); and flavonoids santin 3, jaceidin 2 and centaureidin 1 (Long et al. 2003). The lipophilic flavonol, 6-hydroxykaempferol 3,7,4'-trimethyl ether, called tanetin, was found in the leaf, flower and seed of feverfew together with the known 6-hydroxykaempferol 3,7-dimethyl ether, quercetagenin 3,7-dimethyl

ether and quercetagenin 3,7,3'-trimethyl ether (Williams et al. 1995). The lipophilic flavonoids in leaf and flower were found to be methyl ethers of the flavonols 6-hydroxykaempferol and quercetagenin (Williams et al. 1999b). Apigenin and two flavone glucuronides were present in glandular trichomes on the lower epidermis of the ray florets. The structures of the four 6-hydroxyflavonol methyl ethers of *T. parthenium* were found to be 6- rather than 7-*O*-methylated, and tanetin was revised as 6-hydroxykaempferol 3,6,4'-trimethyl ether. The vacuolar flavonoids of feverfew were dominated by the presence of apigenin and luteolin 7-glucuronides; nine other glycosides were also present. Some rare compounds found in feverfew included guaianolides, 8 α -hydroxystafiatin, endoperoxide tanaparthin- α -peroxide, canin, 10-epi-canin and secotanapartholide A and B (Todorova and Evstatieva 2001).

Three flavones, 3-hydroxyflavone, kaempferol (3,4',5,7-tetrahydroxyflavone) and fisetin (3,3',4',7-tetrahydroxyflavone), and a flavanone naringenin (4',5',7-trihydroxyflavanone) were isolated from the aerial parts (Shafaghat and Salimi 2008).

Antioxidant phenolic acid compounds 3,5-, 4,5- and 3,4-di-*O*-caffeoylquinic acids (DCQAs) were purified from feverfew (Wu et al. 2007). Polyphenolic compounds (g/kg dry matter) in the aerial feverfew plant parts were determined as follows: chlorogenic acid 6.45 g, 3,5-DCQA (dicaffeoylquinic acid) 30.08 g, 4,5, DCQA 5.61 g, total caffeoyl derivatives 42.14 g, total dihydroxycinnamic acid derivatives 57.21 g, total flavonoids 13.97 g, total dihydroxycinnamic acid derivatives+flavonoids 71.18 g and total polyphenolic compounds 81.12 g (Fraisie et al. 2011).

Feverfew essential oil was found to increase from the beginning of stem formation (0.30 %, v/w) until full bloom (0.83 %, v/w) (Hendriks et al. 1996). During the development of the plant, the content of camphor rose from 28 to 48 %, whereas the amount of chrysanthenyl acetate decreased from 30 to 22 %. In none of the oil samples investigated could the potentially toxic monoterpenes α - or β -thujone be detected. They found that the yield of parthenolide per individ-

ual plant gradually increased from about 10 mg at study commencement to about 20 mg when the plant was in full bloom (Hendriks et al. 1997). Parthenolide was present in the leaves and flower heads, but not in the stems. Drying at ambient temperature and lyophilization had no negative influence on the yield of parthenolide per individual plant.

Twenty components were identified in the essential oil of aerial parts of *T. parthenium* in the eastern region of Kosova, constituting 885 of the oil (Haziri et al. 2009). The major components were camphor 63 % and camphene 9.6 %, indicating the occurrence of camphor/camphene chemotype in Kosova. Other components included *p*-cymene 3.3 %, bornyl acetate 3 %, chrysanthenone 1.3 % and the remainder all <1 %: tricylene, α -thujene, α -pinene, β -pinene, α -phellandrene, α -terpinene, pino-carvone, borneol, terpinene-4-ol, *p*-cymen-8-ol, α -terpineol, myrtenal, eugenol, *trans*-myrtenolacetate, isobornyl-2-methylbutanoate and caryophyllene oxide. The volatile fraction of the essential oil of feverfew grown in Belgium was characterized by high camphor (44 %) and *trans*-chrysanthenyl acetate (23 %) contents (de Pooter et al. 1989).

Twenty-three components were identified in the essential oil of *T. parthenium* aerial plant parts from Turkey representing 90.1 % of the oil (Akpulat et al. 2005). The main constituents were camphor (56.9 %), camphene (12.7 %), *p*-cymene (5.2 %) and bornyl acetate (4.6 %). Other components identified include tricylene, α -thujene, α -pinene, β -pinene, α -phellandrene, α -terpinene, γ -terpinene, chrysanthene, pino-carvone, borneol, terpinen-4-ol, *p*-cymen-8-ol, α -terpineol, myrtenal, carvacrol, eugenol, *trans*-myrtenol acetate, isobornyl 2-methyl butanoate and caryophyllene oxide. Twenty-nine components were identified in feverfew essential oil from Iran (Mohsenzadeh et al. 2011). The highest yield was extracted at the flowering stage, and the major components were camphor (18.94 %), bornyl acetate (18.35 %), camphene (13.74 %), bornyl isovalerate (3.15 %), borneol (10.93 %), juniper camphor (6.23 %) and β -eudesmol (2.65 %).

Tissue cultures of *T. parthenium* afforded significant amounts of two coumarins, scopoletin and isofraxidin together with stigmasterol and sitosterol (Banthorpe and Brown 1989). These two coumarins were either absent or were very minor compounds in the parent plant.

Leaf Phytochemicals

Water-soluble flavone glycosides detected in the leaves were identified as apigenin 7-glucuronide, luteolin 7-glucuronide, luteolin 7-glucoside and chrysoeriol 7-glucuronide (Williams et al. 1995). Murch et al. (1997) reported minute amount up to 2.45 µg/g of melatonin (N-acetyl-5-methoxytryptamine) in the leaves which was lower than that found in the flowers of St. John's wort (4.39 µg/g) and *Scutellaria baicalensis* (7.11 µg/g). The following flavonoids were detected in feverfew leaves: flavones, luteolin, scutellarein-6-methyl ether (hispidulin), scutellarein-6-4'-dimethyl ether (pectolinarin), 6-hydroxyluteolin 6-methyl ether (nepetin), 6-hydroxyluteolin 6,3' -dimethyl ether (jaceosidin); flavonol, quercetagenin 3,6-dimethoxy ether (axillarin) (Ivancheva et al. 1998).

Parthenolide, tanaparthin- α -peroxide, tanaparthin- β -peroxide, 3- β -hydroxycostunolide and canin (Kaplan et al. 2002); parthenolide and epoxyartemorin (Sumner et al. 1992) were isolated from the leaves. Leaves of field-grown plants had higher concentration of parthenolide (1.85 % w/w dw) than those from hydroponic plants (0.38 % w/w dw) (Pedneault et al. 2002). From the leaves, isolated sesquiterpene lactones were identified as parthenolide, epoxysantamarin, 3 β -hydroxyparthenolide and secotanapartholide A, and flavonoids identified as santin, apigenin, luteolin and quercetin (Rateb et al. 2007). Forty compounds were identified in the leaf essential oil, and the major compounds were camphor 37.7 %, chrysanthenyl acetate 33.8 % and terpin-1-ol 5.14 % (Rateb et al. 2007). Other minor components included butyl acetate, tricyclene, α -pinene, camphene, sabinene, β -pinene, β -myrcene, *p*-cymene, limo-

nene, β -phellandrene, 1,8-cineole, γ -terpinene, terpinolene, *p*-cymene, pinocarvone, borneol, terpin-4-ol, α -terpineol, linalool acetate, bornyl acetate, citronellal hydrate, thymol, *E*-pinocarvyl acetate, carvacrol, α -copaene, *E*-caryophyllene, α -humulene, *E*- β -farnesene, germacrene D, Ar-curcumen, isobornyl-2-methyl butyrate, Σ -cadinene, *Z*-chrysanthenyl angelate, bornyl angelate, β -caryophyllene oxide, globulol, viridiflorol, *E,E*-farnesol and *E,E*-farnesyl acetate. Shafaghat et al. (2009) found that feverfew leaf oil was characterized by a high amount of camphor (56.4 %), whereas in the stem oil, camphor (26.0 %), *trans*- β -ocimene (23.6 %) and germacrene-D (15.0 %) were the major constituents.

Root Phytochemicals

The roots of *Tanacetum parthenium* transformed with *Agrobacterium rhizogenes* afforded, in addition to the known coumarin isofraxidin, a new isofraxidin drimenyl ether which was elucidated as 9-epipectachol B (Kisiel and Stojakowska 1997). Twenty components (92 % of essential oil) were identified in the essential oil of *T. parthenium* roots and rhizomes (Mojab et al. 2007). Camphor (30.2 %), (*Z*)-chrysanthenyl acetate (26.5 %), α -farnesene (11.1 %) and spathulenol (8.2 %) were the major components. Other components included bornyl angelate (3.3 %), bornyl acetate (3.1 %), ethyl myristate (1.8 %), fenchone (1.5 %), 1-hexanol (1.7 %), 7-benzofuranol (1.3 %), hexanal (1.1 %), β -myrcene (0.8 %), β -caryophyllene (0.4 %), α -pinene (0.3 %), *p*-cymene (0.3 %), carvacrol (0.2 %), borneol (0.1 %), isobornyl formate (0.1 %), isothujyl acetate (0.1 %) and β -bisabolene (0.1 %). The main components of the root oil were α -pinene (50.0 %), *trans*- β -farnesene (13.8 %) and bicyclogermacrene (11.0 %) (Shafaghat et al. 2009).

In feverfew hairy root cultures treated with methyl jasmonate (MJ) increased accumulation of spiroketal enol ether type diacetylenes of known deterrent activity about twofolds (Stojakowska et al. 2002). Salicylic acid (SA)

transiently reduced a content of constitutive spiroketal enol ethers, common for all root clones, but selectively enhanced accumulation of *cis*-C13-spiroketal enol ether epoxide ((*E*)-3,4-epoxy-2-(2,4-hexadiynylidene)-1,6-dioxaspiro[4.4]nonane) (2), present in clone M2. The maximum total acetylene content (≈ 2.5 and 1.1 % dry weight in clones M2 and I2, respectively) was observed after 72–96 hours MJ treatment. Simultaneous addition of SA and MJ to the culture medium increased accumulation of the epoxide in clone M2 (up to sixfold increase compared with the control).

Chemicals in Feverfew Extracts and Products

In the European Patent Specification EP 1 367 993 B1 titled 'Use of a feverfew extract for regulating skin ageing factors', Martin and Salio (2002) the inventors stated that to-date, the chemical constituents of whole feverfew extract include, but are not limited to apigenin-7-glucoside, apigenin-7-glucuronide, 1- β -hydroxy-arbusculin, 6-hydroxykaempferol-3,7-4'-trimethylether (tanetin), 6-hydroxykaempferol-3,7-dimethyl ether, 8- β -reynosin, 10-epicanin, ascorbic acid, β -carotene, calcium, chromium, chrysanthemolide, cosmosine, chrysanthemum, chrysarten-A, chrysarten-C, chrysoeriol-7-glucuronide, cobalt, β -costunolide, epoxyartemorin, luteolin-7-glucoside, luteolin-7-glucuronide, mangnoliolide, tanaparthin, parthenolide, reynosin, quercetagenin-3,7,3'-trimethylether, quercetagenin-3'7- dimethylether, 3,7,3'-trimethoxyquercetagenin, tanaparthin-1 α ,4 α -epoxide and tanaparthin-1 β ,4 β -epoxide-3- β -hydroxy-parthenolide. In the US Patent US 6224875 B1, entitled '*Tanacetum parthenium* extract and method of obtaining same', the inventors Bombardelli and Morazzoni (2001) stated that *Tanacetum parthenium* contained various volatile oils having mono- and/or sesquiterpene components, flavonoids, tannins and pyrethrin, as well as terpenoids of the family of sesquiterpene lactones known as germacranolides, guaiano-

lides and eudesmanolides. These latter compounds were found to be characterized by an α -unsaturated γ -lactone structure and to comprise in particular the compounds known as parthenolide, 3- β -hydroxy-parthenolide, costunolide, 3- β -hydroxy-costunolide, artemorin, 8- α -hydroxy-estafiatin and chrysanthemum. The presence of these sesquiterpene lactones had been considered necessary for the extracts to achieve pharmacological activity in commercial and authenticated feverfew products by (Heptinstall et al. 1992). Heptinstall et al. (1992) found authenticated *Tanacetum parthenium* grown in the United Kingdom contained a high level of parthenolide in leaves, flowering tops and seeds but a low level in stalks and roots; the level of parthenolide in powdered leaf material declined during storage and purported feverfew products varied widely in their parthenolide content and in some products parthenolide was not detected.

Antioxidant Activity

Major polyphenolic acid compounds in feverfew with potent DPPH* scavenging activities were characterized as 3,5-, 4,5- and 3,4-di-*O*-caffeoylquinic acids (DCQAs) (Wu et al. 2007). Total antioxidant capacity (%) (DPPH scavenging activity) of feverfew aerial plant parts was 7.89 %, and contribution from the main caffeoyl derivatives was as follows: chlorogenic acid 8.49 %, 3,5- DCQA (dicaffeoylquinic acid) 48.92 %, 4,5-DCQA 9.12 % and total caffeoyl derivatives 66.53 % (Fraisie et al. 2011).

A parthenolide-depleted extract of feverfew (PD-Feverfew), which was free of sensitization potential, was found to possess free radical scavenging activity against a wide range of reactive oxygen species and with greater activity than vitamin C (Martin et al. 2008). PD-Feverfew had a fivefold greater scavenging activity for oxygen and hydroxyl radicals than ascorbic acid and threefold greater scavenging activity for ferric radicals than ascorbic acid. PD-Feverfew had the greatest scavenging activity against ferric radicals followed by oxygen, hydroxyl and peroxynitrate

radicals, respectively. PD-Feverfew was also effective in scavenging superoxide anion as measured by using a superoxide dismutase (SOD) assay kit. The IC_{50} of SOD scavenging activity for PD-Feverfew was 2.74 $\mu\text{g/ml}$ and that for ascorbic acid was 34.8 $\mu\text{g/ml}$. Thus, the SOD activity of PD-Feverfew was 13-fold greater than that of ascorbic acid. In-vitro, PD-Feverfew restored cigarette smoke-mediated depletion of cellular thiols, attenuated the formation of UV-induced hydrogen peroxide and reduced pro-inflammatory cytokine release. PD-Feverfew was also found to protect keratinocytes from cigarette smoke-induced ROS formation. Cellular toxicity as measured by lactate dehydrogenase (LDH) release was also dose-dependently reversed by PD-Feverfew treatment. In-vivo, topical PD-Feverfew reduced UV-induced epidermal hyperplasia, DNA damage and apoptosis. In a clinical study PD-Feverfew treatment significantly reduced erythema versus placebo 24 hours post-UV exposure. The study showed that parthenolide-depleted extract of feverfew may protect skin from the numerous external aggressions encountered daily by the skin and reduce the damage to oxidatively challenged skin.

Anticancer/Cytotoxicity Activity

In-Vitro Studies

Parthenolide, a bioactive constituent from feverfew, induced mitochondrial dysfunction and apoptosis of human colorectal cancer cell line COLO205 (Zhang et al. 2004b). This action was found to be mediated by proapoptotic Bcl-2 family members relaying the cell death signalling elicited by parthenolide from caspase 8 to downstream effector caspases such as caspase 3 and eventually to cell death. It was also demonstrated that intracellular thiols and calcium equilibrium played a critical role in parthenolide-induced apoptotic cell death (Zhang et al. 2004a). Parthenolide rapidly depleted intracellular thiols, including both free glutathione (GSH) and protein thiols and concomitantly increased intracellular reactive oxygen species (ROS) and calcium levels in a dose- and time-dependent manner.

The alcoholic feverfew flower extract and parthenolide were the most potent, showing 100 % inhibition of Ehrlich ascites carcinoma cell viability at their highest concentration, but the alcoholic flower extract was slightly more potent than parthenolide at lower concentrations (Rateb et al. 2007). The aqueous leaf and flower extracts showed little in-vitro cytotoxic activity (60 and 65 %), respectively, at their high concentration. In an earlier study, at concentrations above 5.0 μM and an exposure time of 24 hours, parthenolide from feverfew inhibited cell growth of mouse fibrosarcoma (MN-11) and human lymphoma (TK6) cell lines in an irreversible fashion (Ross et al. 1999). However, at lower concentrations, i.e. 2.5 μM , the effect was reversible; parthenolide acted in a cytostatic fashion over multiple cell generations for both cell lines. After 24 hours exposure to 2.5 μM parthenolide, approx. 85 % of cells were able to continue cell cycling on removal of the chemical. The mechanism of the reversible growth inhibition was uncertain.

Parthenolide, from feverfew, was shown to preferentially induce acute myelogenous leukaemia stem cells to undergo apoptosis and importantly displayed no discernable effect on normal blood cells (Guzman and Jordan 2005). Anderson and Bejcek (2008) demonstrated that treatment of glioblastoma cells (brain tumour cells) with parthenolide resulted in rapid apoptosis through caspase 3/7 without a suppression of NF-kappaB activity. Studies showed parthenolide to be a promising metabolic inhibitor to retard tumorigenesis and to suppress tumour growth of cancer cells without harming normal cells (Pajak et al. 2008; Mathema et al. 2012). Parthenolide was shown to inhibit NF-kappaB- and STATs-mediated antiapoptotic gene transcription and amplified the apoptotic signal through the sensitization of cancer cells to extrinsic apoptosis, induced by TNF-alpha (Pajak et al. 2008; Mathema et al. 2012).

Kang et al. (2001) found that parthenolide potently inhibited the lipopolysaccharide (LPS)-induced interleukin IL-12 production in mouse macrophages in a dose-dependent manner. Parthenolide decreased significantly the binding activity to the kappaB site in the macrophage.

In further studies they (Kang et al. 2002) found that parthenolide strongly potentiated 1 α ,25-dihydroxyvitamin D(3)-induced differentiation of human leukaemia HL-60 cells into monocytes via the inhibition of NF-kappa B activity and provided evidence that inhibition of NF-kappa B activation could be a prerequisite to the efficient entry of promyelocytic leukaemia cells into a differentiation pathway. In another study, parthenolide, from feverfew, induced apoptosis in pre-B acute lymphoblastic leukaemia (ALL) lines, including cells carrying the t(4;11) (q21;q23) chromosomal translocation (Zunino et al. 2007). Parthenolide induced rapid apoptotic cell death distinguished by loss of nuclear DNA, externalization of cell membrane phosphatidylserine and depolarization of mitochondrial membranes at concentrations ranging from 5 to 100 μ M and production of reactive oxygen species (ROS)-specific dyes, such as nitric oxide and superoxide anion. Parthenolide-induced elevation of hypochlorite anion was observed only in the two t(4;11) lines. The data suggested parthenolide may have potential as a potent and novel therapeutic agent against pre-B ALLs. In subsequent studies, they showed that parthenolide treatment activated stress-signalling proteins in high-risk acute lymphoblastic leukaemia cells with chromosomal translocation t(4;11) (Zunino et al. 2010). Parthenolide was shown to be a potent anti-multiple myeloma cancer stem cell (MM-CSC) agent (Gunn et al. 2011). It demonstrated preferential toxicity towards MM-CSCs over non-tumorigenic MM cells. In a review of parthenolide Mathema et al. (2012) reported that parthenolide induced reactive oxygen species (ROS) exclusively in tumour cells leading to proapoptotic action; parthenolide actively interfered with microtubule formation by reducing impaired control of spindle positioning, a factor favouring tumour invasiveness in cancer cells and parthenolide-mediated STAT proteins, transcriptional factors responding to extracellular ligands that broadly mediate diverse biological functions such as cell proliferation, differentiation, transformation and apoptosis.

Parthenolide was found to inhibit proliferation of metastatic human lung cancer subline,

PGCL3 cells, after 24 hours treatment the IC₅₀ value was 17.60 μ mol/l (Zhong et al. 2005). Parthenolide reduced significantly the activity of urokinase-type plasminogen activator secreted by PGCL3 cells and downregulated the expression level of urokinase-type plasminogen activator protein. The authors concluded that the antitumour activity of parthenolide involved the activity and expression of urokinase-type plasminogen activator. Parthenolide inhibited proliferation of human lung carcinoma (A549), human medulloblastoma (TE671), human colon adenocarcinoma (HT-29) and human umbilical vein endothelial cells (HUVEC) in-vitro with the following IC₅₀ values: 4.3, 6.5, 7.0 and 2.8 μ M, respectively (Parada-Turska et al. 2007). In another study, parthenolide inhibited proliferation of rabbit synoviocytes cell line HIG-82 and human rheumatoid arthritis fibroblast-like synoviocytes (RA-FLS) in-vitro (Parada-Turska et al. 2008). The proliferation of human skin fibroblasts (HSF) was inhibited less effectively.

Parthenolide exerted in-vitro stimulatory activity on tubulin assembly by inducing the formation of well-organized microtubule polymers in human breast cancer MCF-7 cells (Miglietta et al. 2004). It was found that parthenolide-induced alterations of microtubule network and nuclear morphology occurred only after combined exposures to paclitaxel. Further, the growth of MCF-7 cells was significantly inhibited by parthenolide, which enhanced paclitaxel effectiveness. The authors concluded that the antimicrotubular and antiproliferative effects of parthenolide, well-known microtubule-stabilizing anticancer agent, may influence paclitaxel activity and may be utilized in developing new combinational anticancer strategies. In separate earlier studies, Patel et al. (2000) found that parthenolide mimicked the effects of IkappaBalpha by inhibiting NF-kappaB DNA binding activity and manganese superoxide dismutase (Mn-SOD) expression and increasing paclitaxel-induced apoptosis of breast cancer cells. In other studies, feverfew ethanol extract inhibited the growth of two human breast cancer cell lines (Hs605T and MCF-7) and one human

cervical cancer cell line (SiHa) with a half-effective concentration (EC_{50}) of 1.5 mg/ml against Hs605T, 2.1 mg/ml against MCF-7 and 0.6 mg/ml against SiHa (Wu et al. 2006). Among the tested constituents of feverfew (i.e. parthenolide, camphor, luteolin and apigenin), parthenolide showed the highest inhibitory effect with an EC_{50} against Hs605T, MCF-7 and SiHa of 2.6, 2.8 and 2.7 μ g/ml, respectively. Also it was found that apigenin and luteolin might have moderate to weak synergistic effects with parthenolide on the inhibition of cancer cell growth of Hs605T, MCF-7 and SiHa. In a more recent study, parthenolide and a synthetic compound, 3-isopropyl-2-methyl-4-methyleneisoxazolidin-5-one, with the same α -methylene- γ -lactone motif as in parthenolide, were found to reduce the number of viable breast cancer MCF-7 and MDA-MB-231 cells, with half maximal inhibitory concentration values between 6 and 9 μ M (Wyřębska et al. 2013). Both compounds dose-dependently inhibited incorporation of [(3)H]thymidine, upregulated Bax and downregulated Bcl-2 mRNA. In MCF-7 cells, MZ-6 induced early apoptosis and cell cycle arrest in G0/G1 phase, and its effect was much stronger compared with parthenolide. In MDA-MB-231 cells, both tested compounds had similar effect and induced mostly late apoptosis.

Treatment of sesquiterpene lactones isolated from *Calea urticifolia* and *Tanacetum parthenium* at a low concentration (1 μ M) significantly blocked 3-isobutyl-1-methylxanthin (IBMX)-induced melanogenesis, but did not induce the inhibitory activity of B16 melanoma cell growth (Ohguchi et al. 2009). In another study, parthenolide reduced the number of viable adherent cells in melanoma cultures with an MIC value of 4 μ mol/l (Lesiak et al. 2010). Melanoma cell death accompanied by mitochondrial membrane depolarization and caspase-3 activation was observed as the result of parthenolide application. Reactive oxygen species level was not significantly increased in melanoma cells. However, preincubation of parthenolide with the thiol nucleophile *N*-acetyl-cysteine protected melanoma cells

from parthenolide-induced cell death, suggesting the reaction with intracellular thiols as the mechanism responsible for parthenolide activity. Thus, parthenolide could have potential as a drug candidate for further testing in melanoma therapy.

Treatment of bladder cancer cells with parthenolide resulted in a significant decrease in cell viability (Cheng and Xie 2011). Parthenolide induced apoptosis through the modulation of Bcl-2 family proteins and poly (ADP-ribose) polymerase degradation. Treatment with parthenolide led to G1 phase cell cycle arrest in 5637 cells by modulation of cyclin D1 and phosphorylated cyclin-dependent kinase 2. Parthenolide also inhibited the invasive ability of bladder cancer cells.

Animal Studies

Mice fed with parthenolide (1 mg/day) showed a delayed onset of skin papilloma incidence induced by UVB, a significant reduction in papilloma multiplicity (papilloma/mouse) and sizes when compared with the UVB-only group (Won et al. 2004). It was found that noncytotoxic concentrations of parthenolide inhibited UVB-induced activator protein-1 DNA binding and transcriptional activity. In addition, parthenolide pretreatment also inhibited c-Jun-N-terminal kinase (JNK) and p38 kinase activation leading to the sensitization of JB6 cells to UVB-induced apoptosis. In subsequent studies, they demonstrated that parthenolide sensitized UVB-induced apoptosis via protein kinase C (PKC) pathways (Won et al. 2005). Parthenolide pretreatment of JB6 murine epidermal cells enhanced membrane translocation of PKCdelta, but inhibited the translocation of PKCzeta. Further, pretreatment with a specific PKC delta inhibitor, rottlerin, completely diminished the sensitization effect of parthenolide on UVB-induced apoptosis. Similarly when cells were transiently transfected with dominant negative PKCdelta or wild-type PKCzeta, the sensitization effect of parthenolide on UVB-induced apoptosis was also drastically reduced.

Antiviral Activity

Feverfew was one of 32 plant herbs that exhibited inhibitory activity against Epstein–Barr virus early antigen (EBV-EA) activation in Raji cells promoted by phorbol ester, 12-*O*-tetradecanoylphorbol-13-acetate (TPA) (Kapadia et al. 2002). Studies showed that parthenolide inhibited the growth of the Epstein–Barr virus (EBV)-positive Burkitt lymphoma cell line, Raji, and activated the transcription of BZLF1 and BRLF1 by inhibiting NF- κ B activity (Li et al. 2012). Further, when parthenolide was used in combination with ganciclovir (GCV), the cytotoxic effect of parthenolide was amplified, suggesting that the induction of lytic EBV infection with parthenolide in combination with GCV may be a viral-targeted therapy for EBV-associated Burkitt lymphoma.

Neurological/Migraine Prophylactic Activity

The exact mechanism of migraine pathophysiology is still uncertain. Based on therapeutic and triggered migraine studies, serotonin receptors, nitric oxide, calcitonin gene-related peptide, pituitary adenylate cyclase-activating polypeptide and prostanoids have been demonstrated to be specific chemical mediators of migraine Charles (2013). Numerous mechanisms have been proposed for the action of feverfew in migraine and include inhibition of inflammation, inhibition of serotonin release, inhibition of prostaglandin synthesis, inhibition of platelet aggregation and secretion, inhibition of polymorphonuclear leucocyte degranulation, inhibition of phagocytosis of human neutrophils, inhibition of mast cell release of histamine minimizing damage to endothelium and inhibition of VSMC and modulating vasoconstriction (Biggs et al. 1992; Kemper 1999; Colodny et al. 2003). According to Rodriguez-Sainz et al. (2013) migraine, epilepsy and stroke are highly prevalent neurological disorders, often comorbid. They share diverse pathophysiological mechanisms that explain the use of similar drugs on certain occasions.

In-Vitro Studies

Sesquiterpene lactones, parthenolide, 3- β -hydroxy parthenolide, secotanapartholide A, canin and artecamin isolated from feverfew inhibited secretion of granular contents from platelets and neutrophils (Groenewegen et al. 1986). All the active compounds contained a α -methylene butyrolactone unit that could have been responsible for the antisecretory activity in extracts of feverfew. This may be relevant to the therapeutic value of feverfew in migraine and other conditions. *T. parthenium* samples established from seeds from 10 different regions were found to vary significantly within and between samples in migraine prophylactic activity in-vitro (Marles et al. 1992). Serotonin release inhibition from bovine platelets was found to correlate significantly with the content of germacranolide sesquiterpene lactone, parthenolide, although other sesquiterpene lactones from this plant and other Asteraceae species (including *T. vulgare*) were also shown to be active. Feverfew powder was found to be more potent than any of its extract or parthenolide alone in its antiserotonergic activity (Mittra et al. 2000). Feverfew extract potently and directly blocked 5-HT_{2B} and 5-HT_{2A} receptors and neuronally released 5-hydroxytryptamine (%-HT). Both parthenolide and Feverfew extract showed a time dependency in their action. The extract when degraded thermally up to 10 % could significantly block the 5-HT receptors and neuronal release of 5-HT; however, on further degradation it lost its inhibitory capacity markedly. Similar results were observed in rats fed orally with undergraded and degraded feverfew powder and injected i.p. with parthenolide. Feverfew powder was more effective than any of its extracts or pure parthenolide. Degraded feverfew extracts showed a marked decrease in their antiserotonergic activity.

The anti-migraine mechanism of feverfew supercritical extract was investigated in-vitro using the mouse macrophage cell line (RAW 264.7) by Aviram et al. (2012). Feverfew extract was found to inhibit both nitric oxide (NO) and TNF- α production in a dose-dependent manner with complete inhibition of NO occurring at 5 μ g/ml. Feverfew inhibition of NO was attributed

to the downregulation of both eNOS and iNOS enzymes at the translational and/or posttranslational level. Fukuda et al. (2000) demonstrated that parthenolide exerted potent inhibitory effects on the promoter activity of the iNOS gene in human monocyte cell line THP-1 cells in a dose-dependent manner. The increase in iNOS promoter-dependent reporter gene activity induced by the tumour-promoting phorbol ester, 12-*O*-tetradecanoylphorbol-13-acetate (TPA), was effectively suppressed by parthenolide, with an IC₅₀ of 2 µM.

In cultured lipopolysaccharide (LPS)-stimulated BV-2 microglia pretreatment with parthenolide caused a dose-dependent reduction of interleukin-6 (IL-6) secretion; at 5 µm, the highest concentration tested, it also reduced the secretion of TNF-α (54 %) (Magni et al. 2012). The reduction of microglial activation by inhibition of proinflammatory agents may help attenuate the onset and intensity of acute migraine attacks. The in-vitro results provided an additional explanation for the efficacy of orally administered *T. parthenium* as an anti-migraine agent.

Crude chloroform extracts of fresh feverfew leaves (rich in sesquiterpene lactones) and of commercially available powdered leaves (lactone-free) produced dose-dependent inhibition of the generation of thromboxane B₂ (TXB₂) and leukotriene B₄ (LTB₄) by ionophore- and chemoattractant-stimulated rat peritoneal leucocytes and human polymorphonuclear leucocytes (Sumner et al. 1992). Approximate IC₅₀ values were in the range of 5–50 µg/ml. Isolated lactones (parthenolide, epoxyartemisin) were also inhibitory, with approximate IC₅₀ values in the range of 1–5 µg/ml. They concluded that feverfew contained a complex mixture of sesquiterpene lactone and non-sesquiterpene lactone inhibitors of eicosanoid synthesis of high potency and that these biochemical actions may be relevant to the claimed therapeutic actions of the herb for fever, arthritis and migraine. The major flavonol and flavone methyl ethers of both *Tanacetum parthenium* and *T. vulgare* variously inhibited the major pathways of arachidonate metabolism in leucocytes (Williams et al. 1999b). There were significant differences in potency,

with the tansy 6-hydroxyflavones less active than the feverfew 6-hydroxyflavonols as inhibitors of cyclooxygenase and 5-lipoxygenase. An ethanol extract of *T. parthenium* aerial parts showed high affinity for the GABA(A)-benzodiazepine site, and the bioactive apigenin isolated may be responsible for CNS (central nervous system) effects of *T. parthenium* extracts which were also used for epilepsy and convulsions in Holland (Jäger et al. 2006, 2009).

Animal Studies

Tanacetum parthenium extract enriched in parthenolide significantly reduced nitroglycerin-induced Fos expression in the nucleus trigeminalis caudalis in an animal model of migraine (Tassorelli et al. 2005). Purified parthenolide inhibited nitroglycerin-induced neuronal activation in additional brain nuclei and, significantly, the activity of nuclear factor kappaB. The findings strongly suggested parthenolide to be the component responsible for the biological activity of *Tanacetum parthenium* as regards its anti-migraine effect.

Clinical Studies

In a double-blind, placebo-controlled trial wherein eight patients received capsules containing freeze-dried feverfew leaf powder and nine placebo, those who received placebo had a significant increase in the frequency and severity of headache, nausea and vomiting with the emergence of untoward effects during the early months of treatment (Johnson et al. 1985). The group given capsules of feverfew showed no changes in the frequency or severity of symptoms of migraine. The authors concluded that feverfew taken prophylactically prevented attacks of migraine. In another randomized, double-blind, placebo-controlled crossover study involving 72 volunteers with each treatment limb lasting 4 months before crossover, treatment with feverfew was associated with a reduction in the mean number and severity of migraine attacks in each 2-month period and in the degree of vomiting; duration of individual attacks was unaltered (Murphy et al. 1988). Visual analogue scores also

indicated a significant improvement with feverfew. There were no serious side effects. In a double-blind placebo-controlled crossover trial of 57 migraine sufferers, it was found that feverfew caused a significant reduction in pain intensity compared with the placebo treatment (Palevitch et al. 1997). Further, a marked reduction was recorded concerning the severity of the typical symptoms that were usually linked to migraine attacks, such as vomiting, nausea, sensitivity to noise and sensitivity to light. Transferring the feverfew-treated group to the placebo treatment resulted in an augmentation of the pain intensity as well as an increase in the severity of the linked symptoms. In contrast, shifting the placebo group to feverfew therapy resulted in a reduction of the pain intensity as well as in the severity of the linked symptoms. In another study of 24 patients (women 19–61 years old), administration of feverfew once daily (5 ml of the sap) for 30–60 days was found to significantly reduced migration index in 8 patients and less significantly in 5 patients, suggesting that feverfew may be beneficial in migraine prophylaxis as an additive drug (Prusiński et al. 1999).

In a randomized, double-blind, placebo-controlled, multicenter, parallel-group study involving 170 patients suffering from migraine, treatment of 89 patients with CO(2) extract of feverfew (MIG-99, 6.25 mg three times daily) and 81 with placebo showed that MIG-99 was effective and had a favourable benefit–risk ratio (Diener et al. 2005). The migraine frequency decreased from 4.76 by 1.9 attacks per month in the MIG-99 group and by 1.3 attacks in the placebo group. Logistic regression of responder rates showed an odds ratio of 3.4 in favour of MIG-99. Adverse events possibly related to study medication were 9/107 (8.4 %) with MIG-99 and 11/108 (10.2 %) with placebo ($P=0.654$). Earlier in a double-blind, multicenter, randomized placebo-controlled dose–response study, they found that MIG-99 was effective only in a small predefined subgroup of patients with at least four attacks during the 28-day baseline period where the most favourable benefit–risk ratio was observed with a dosage of three capsules of 6.25 mg MIG-99 extract per day (Pfaffenrath

et al. 2002). Because of the low number of patients, they asserted that the findings needed to be verified in a larger sample. In a prospective, open-label study in 12 patients diagnosed with migraine without aura, 12-week treatment with *T. parthenium* 300 mg plus *Salix alba* 300 mg (Mig-RL) twice daily was found to reduce the frequency of migraine attacks and their pain intensity and duration (Shrivastava et al. 2006). In a multicenter pilot study, 60 subjects treated 208 evaluable attacks of migraine over a 1-month period, 45 subjects treated 163 attacks with sublingual feverfew/ginger and 15 subjects treated 58 attacks with a sublingual placebo preparation (Cady et al. 2011). The study showed that sublingual feverfew/ginger appeared safe and effective as a first-line abortive treatment for a population of migraineurs who frequently experience mild headache prior to the onset of moderate to severe headache. In a recent randomized study of 69 women volunteers with chronic migraine, conducted over 10 weeks, an improvement of quality of life and better analgesic effect was found with acupuncture combined with feverfew compared with acupuncture or feverfew alone (Ferro et al. 2012).

Several clinical studies reported that feverfew had mixed results on migraine prophylaxis. In a randomized, double-blind, placebo-controlled, crossover trial to investigate migraine prophylaxis, 44 patients completed the 9-month study (De Weerd et al. 1996). A prophylactic effect could not be demonstrated for our feverfew preparation, but the patients seemed to have a tendency to use fever symptomatic drugs during the period they used feverfew.

Review Studies

Vickers (1985) reported that in a study of feverfew users for migraine, 18 % reported adverse effects, the most troublesome being mouth ulceration (11 %). Feverfew can induce more widespread inflammation of the oral mucosa and tongue, often with lip swelling and loss of taste. In a systematic review of randomized, placebo-controlled, double-blind trials ($n=5$ which met the inclusion/exclusion criteria), the clinical effectiveness of feverfew in the prevention of

migraine was not established conclusively (Vogler et al. 1998). The majority favoured feverfew over placebo but important caveats still existed.

In a systemic review of double-blind randomized controlled trials (RCTs) assessing the clinical efficacy and safety of feverfew versus placebo for preventing migraine, only five trials (343 patients) met the inclusion criteria (Pittler and Ernst 2004). Results from these trials were mixed and did not convincingly establish feverfew to be efficacious for preventing migraine. Only mild and transient adverse events were reported in the included trials. The authors concluded that there was insufficient evidence from randomized, double-blind trials to suggest an effect of feverfew over and above placebo for preventing migraine but that the data reviewed suggested that feverfew presented no major safety problems.

Antiinflammatory Activity

Tanacetum parthenium had been reported to inhibit the release of proinflammatory mediators from macrophages and lymphocytes Amirghofran (2012). Extracts of feverfew aerial plant parts inhibited prostaglandin production by up to 88 %; leaf extracts inhibited prostaglandin production to a lesser extent (58 %) (Collier et al. 1980). Neither the whole plant nor leaf extracts inhibit cyclooxygenation of arachidonic acid, the first step in prostaglandin biosynthesis. Feverfew was found to contain prostaglandin synthetase inhibitors: parthenolide, michefuscalide and chrysanthemyl acetate (Pugh and Sambo 1988). The IC₅₀ values for the in-vitro inhibition of the prostaglandin synthetase (bovine seminal vesicle mitochondrial fraction)-mediated prostaglandin E₂ production from arachidonic acid by parthenolide, michefuscalide and chrysanthemyl acetate were 11.0, 12.1 and 14.2 µM. Pharmacological tests indicated that the flavonol, tanetin, could contribute to the antiinflammatory properties of feverfew by inhibiting the generation of proinflammatory eicosanoids, although it is unlikely to be the only biologically active compound within the plant (Williams et al. 1995). The major flavo-

nol and flavone methyl ethers of *T. parthenium* and *T. vulgare* variously inhibited the major pathways of arachidonate metabolism in leucocytes (Williams et al. 1999b). There were significant differences in potency, with the tansy 6-hydroxyflavones less active than the feverfew 6-hydroxyflavonols as inhibitors of cyclooxygenase and 5-lipoxygenase. An earlier study found that at 10–25 µg/ml feverfew had no effect on the formation of arachidonate metabolites, while at highest concentrations (50–200 µg/ml) it inhibited both cyclooxygenase and lipoxygenase metabolic products in rat leucocytes (Capasso 1986).

Pretreatment of human synovial fibroblasts with either feverfew extracts or purified parthenolide could dose-dependently inhibit the expression of intercellular adhesion molecule-1 (ICAM-1) induced by the cytokines IL-1 (up to 95 % suppression), TNF-alpha (up to 93 % suppression) and, less strongly, interferon-gamma (up to 39 % suppression) (Piela-Smith and Liu 2001). The decrease in ICAM-1 expression was accompanied by a decrease in T-cell adhesion to the treated fibroblasts. The modulation of adhesion molecule expression may be an additional mechanism by which feverfew mediates anti-inflammatory effects. Studies by Kwok et al. (2001) concluded that the antiinflammatory action of parthenolide was attributed to the binding and inhibition of IkappaB kinase beta complex which was known to play a critical role in cytokine-mediated signalling. Parthenolide, the predominant sesquiterpene lactone in feverfew, inhibited the expression of COX-2 and proinflammatory cytokines (TNF alpha and IL-1) in lipopolysaccharide (LPS)-stimulated macrophages (Hwang et al. 1996). The structure-function relationship indicated that the alpha-methylene-gamma-lactone moiety conferred the inhibitory effect. Parthenolide suppressed LPS-stimulated protein tyrosine phosphorylation in the murine macrophage cell line (RAW 264.7). This suppression was correlated with its inhibitory effect on the expression of COX-2 and the cytokines. All three herbal constituents, apigenin (chamomile), ginsenoside Rb(1) (ginseng) and parthenolide (feverfew), inhibited on lipopolysaccharide (LPS)-induced proinflammatory

cytokines IL-6 and/or TNF- α production in murine macrophage cell culture (Smolinski and Pestka 2003). Inhibition of these two cytokines was observed in mice, but did not display the same patterns of inhibition as cell culture data. The results suggested that all three constituents possessed antiinflammatory properties but that cell culture data can only be used to approximate potential effects in animals.

Parthenolide from feverfew, inhibited the myeloid differential factor 88 (MyD88)-dependent pathway by suppressing the activity of inhibitor- κ B kinase (Park et al. 2011). Parthenolide also inhibited nuclear factor- κ B and interferon regulatory factor 3 activation induced by LPS or poly[I:C] and the LPS-induced phosphorylation of interferon regulatory factor 3 as well as interferon-inducible genes such as interferon inducible protein-10. These results suggested that parthenolide could modulate toll-interleukin-1 receptor domain-containing adapter-inducing interferon- β (TRIF)-dependent signalling pathways of toll-like receptors (TLRs) and may be the basis of effective therapeutics for chronic inflammatory diseases.

The alcoholic extracts of leaves and flowers and parthenolide showed significant anti-inflammatory activity (about 65–75 % of the activity of diclofenac sodium after 3 hours and about 55–60 % of the activity of diclofenac sodium after 6 hours) in the yeast-induced rat paw oedema test (Rateb et al. 2007). This was attributed to the presence of high concentration of sesquiterpene lactones, especially parthenolide, and flavonoids.

Feverfew extracts were found to inhibit mitogen-induced tritiated thymidine ([3 H]-TdR) uptake by human peripheral blood mononuclear cells (PBMC), interleukin 2 (IL-2)-induced [3 H]-TdR uptake by lymphoblasts and PGE₂ release by interleukin 1 (IL-1)-stimulated synovial cells (O'Neill et al. 1987). Parthenolide, a major secondary feverfew, also blocked [3 H]-TdR uptake by mitogen-induced PBMC. However, both crude extracts and parthenolide proved cytotoxic to mitogen-induced PBMC and IL-1 stimulated synovial cells, indicating that the pharmacological properties of feverfew may thus

be due to cytotoxicity. A parthenolide-depleted extract of feverfew (PD-Feverfew) was developed to eliminate the risk of skin sensitization from feverfew (Sur et al. 2009). They ascertained that PD-Feverfew was sufficiently depleted of parthenolide since PD-Feverfew did not inhibit TNF- α induced-NF- κ B activity unlike parthenolide containing whole feverfew. PD-Feverfew directly inhibited the activity of proinflammatory enzymes 5-lipoxygenase, phosphodiesterase-3 and phosphodiesterase-4 and inhibited the release of proinflammatory mediators nitric oxide, PGE₂ and TNF- α from macrophages and TNF- α , IL-2, IFN- γ and IL-4 from human peripheral blood mononuclear cells. Further, PD-Feverfew inhibited TPA-induced release of PGE₂ from human skin equivalents. In-vivo, PD-Feverfew inhibited oxazolone-induced dermatitis and was more potent than whole feverfew in reducing TPA-induced dermatitis. Finally the efficacy of PD-Feverfew was confirmed clinically by a reduction in erythema in a methyl nicotinate-induced vasodilation model. Their results indicated PD-Feverfew extract to have potent antiinflammatory activity suggesting that it would be efficacious in relieving inflammation without inducing immune sensitization. Studies showed that parthenolide suppressed inflammation by inhibiting activity of nuclear factor kappa-light-chain enhancer of activated B cells (NF- κ B) (Mathema et al. 2012). Activated NF- κ B is a transcription factor associated with a wide range of cellular responses, including inflammation, immune regulation, survival and proliferation. Parthenolide also acted as inhibitors of inflammasomes, large complex cytosolic proteins that are associated with autoimmunity disorders like gouty arthritis and neurodegeneration.

Vasoprotective Activity

Addition of feverfew extract to the perfusion medium protected the endothelial cell monolayer from perfusion-induced injury and led to a reversible increase in the cAMP content of rabbit aorta segments (Voyno-Yasenetskaya et al. 1988). The results indicated that feverfew may have a

vasoprotective effect in addition to its effects on platelets. Studies showed that treatment of isolated rat aortic VSMC (vascular smooth muscle cells) with parthenolide significantly inhibited the VSMC proliferation by inducing G(0)/G(1) cell cycle arrest (Weng et al. 2009). Expression of IkappaBalpha and Cox-2 were increased and were likely involved in parthenolide inhibitory effect on VSMC proliferation.

Antiplatelet/Antithrombotic Activity

Extracts of feverfew inhibited platelet aggregation and the platelet release reaction (Heptinstall et al. 1988), and the active components were held to be sesquiterpene lactones such as parthenolide. Inhibition of platelet behaviour was found to be via neutralization of sulphhydryl groups either inside or outside the cell. Makheja and Bailey (1982) found that feverfew extracts inhibited ADP-, thrombin- or collagen-induced aggregation of human platelets, but, significantly, did not affect aggregation induced by arachidonic acid. Synthesis of thromboxane B₂ from exogenous 14C-arachidonic acid was also not inhibited. Washed platelets prelabelled with 14C-arachidonic acid responded normally to thrombin by releasing 14C-TXB₂; this was completely blocked by feverfew. A purified platelet phospholipase A₂ was inhibited by feverfew with an IC₅₀ of 0.1 antiplatelet units. However, in a follow-up study of ten patients who had taken feverfew extracts for up to 8 years to control migraine headaches, it was found that the platelets of all treated patients aggregated characteristically to ADP and thrombin and similarly to those of control patients (Biggs et al. 1992). However, aggregation, in response to serotonin, was greatly attenuated in the feverfew users.

The structures of two series of sesquiterpene lactones (the 'α'-series 11, 12 and 16 and the 'β'-series 15, 17 and 18) present in feverfew were revised by Hewlett et al. (1996). The activity of some of these metabolites as well as of the major sesquiterpene lactone present in feverfew, parthenolide and some simple synthetic models as

inhibitors of human blood platelet function was also determined. Extracts of feverfew inhibited secretory activity in blood platelets and polymorphonuclear leucocytes (PMNs) (Heptinstall et al. 1985). Release of serotonin from platelets induced by various aggregating agents (adenosine diphosphate, adrenaline, sodium arachidonate, collagen and U46619) was suppressed by feverfew. Platelet aggregation was consistently inhibited, but thromboxane synthesis was not. Feverfew also inhibited release of vitamin B₁₂-binding protein from PMNs induced by the secretagogues formyl-methionyl-leucyl-phenyl-alanine, sodium arachidonate and zymosan-activated serum. Feverfew did not inhibit the secretion induced in platelets or PMNs by the calcium ionophore A23187. Feverfew extracts were found to inhibit platelet aggregation and the platelet release reaction via neutralization of sulphhydryl groups (Heptinstall et al. 1987, 1988). This was based on the observation that compounds containing sulphhydryl groups such as cysteine and *N*-(2-mercaptopropionyl)glycine prevented the inhibition of platelet behaviour by feverfew. Feverfew and parthenolide dramatically reduced the number of acid-soluble sulphhydryl groups in platelets. Feverfew elicited changes in the metabolism of arachidonic acid that were similar to those observed in glutathione-depleted platelets.

Feverfew extract was found to inhibit interactions of platelets with collagen substrates. (Losche et al. 1987, 1988a, b). Feverfew extract inhibited the deposition of 51-Cr-labelled platelets on both collagens types C III and C IV in a dose-dependent way. Similar concentrations of feverfew extract were needed to inhibit the formation of surface-bound aggregates and to inhibit platelet spreading in both platelet-rich plasma and suspensions of gel-filtered platelets. They found that feverfew extract inhibited uptake as well as liberation of arachidonic acid into/from platelet membrane phospholipids. When aorta segments were perfused in-situ with a physiological salt solution, the addition of feverfew to the solution protected the endothelial cell monolayer from spontaneous injury. The results indicated

that feverfew may have antithrombotic potential. In-vitro studies showed that both feverfew extract and parthenolide were more effective as inhibitors of the [^{14}C]5-HT secretion from platelets and on platelet aggregation induced by some agents and not others and were most effective as inhibitors of the [^{14}C]5-HT secretion (but not the aggregation) induced by phorbol-12-myristate-13-acetate (PMA) (Groenewegen and Heptinstall 1990).

Parthenolide was found to stimulate functional platelet production from human megakaryocyte cell lines and from primary mouse and human megakaryocytes in-vitro (Sahler et al. 2011). Parthenolide enhanced platelet production via inhibition of nuclear factor- κB signalling in megakaryocytes and was independent of the parthenolide-induced oxidative stress response. Additionally, parthenolide treatment of human peripheral blood platelets attenuated activation of stimulated platelets. The results revealed that parthenolide has strong potential as a candidate to enhance platelet production and to dampen undesirable platelet activation. Mathema et al. (2012) also reported that recent in-vitro studies on human megakaryotic and mouse megakaryocytic cell lines showed that parthenolide induced thrombopoiesis through the inhibitory activity of NF- κB and cell cycle arrest.

Immunomodulatory Activity

Studies showed that addition of feverfew extract inhibited phagocytosis of *Candida guilliermondii* and its overall killing in-vitro (Williamson et al. 1988). However, intracellular killing was not affected, suggesting that the apparent defect in total killing merely reflected the failure of uptake. Feverfew leaf extracts prepared in acetone-ethanol contained significantly more parthenolide than extracts in chloroform-PBS (phosphate-buffered saline) or PBS alone (Brown et al. 1997b). Extract bioactivity measured as inhibition of human polymorphonuclear leucocyte (PMNL) chemiluminescence in-vitro followed a similar trend. Extracts inhibited phorbol 12-myristate 13-acetate-induced oxidative burst

by amounts which appeared not solely attributable to parthenolide alone based on the PMNL-bioassay. In another study Brown et al. (1997a) reported that the acetone leaf extracts of *T. parthenium* and *T. vulgare* inhibited phorbol myristate acetate-induced chemiluminescence of human polymorphonuclear leucocytes, with IC_{50}s from 0.79 to 2.46 mg leaf dry weight/ml whole blood. Parthenolide concentration in *T. parthenium* was high 1.72 % leaf dry weight but lower in *T. vulgare*, 0.03 %. Fractionation of crude leaf extracts revealed a number of fractions, in addition to those containing parthenolide, which influenced polymorphonuclear leucocyte activity by >5 %. The effects on phorbol myristate acetate-induced chemiluminescence suggested the activity of the responsible compound(s) was a result of inhibition of protein kinase C, or subsequent events, in polymorphonuclear leucocyte activation in-vitro.

Antiallergic Activity

Feverfew extract dose-dependently inhibited histamine release from rat peritoneal mast cells stimulated with anti-IgE or the calcium ionophore A23187 (Hayes and Foreman 1987). Greater inhibition of anti-IgE-induced histamine release was achieved with feverfew compared with the inhibition of A23187-induced release. Feverfew extract also inhibited anti-IgE-induced histamine release to the same extent in the absence and presence of extracellular glucose. It was concluded that feverfew extract contained a novel type of mast cell inhibitor.

Neuroprotective Activity

In-vitro studies in primary mouse cortical cultures showed that all feverfew sesquiterpene lactones and the α -methylene- γ -lactone moiety were able to activate a series of genes termed the antioxidant response element (ARE) and caused cellular toxicity (Fischedick et al. 2012). The guaianolides were more active and, when lacking

the endoperoxide functionality, less toxic than the germacranolides. Activation of Nrf2/ARE may be useful for the treatment of neurodegenerative disease.

Antiarthritic Activity

In the chronic adjuvant arthritic screen, compounds containing the alpha-methylene-gamma-lactone moiety, the beta-unsubstituted cyclopentenone ring and the alpha-epoxy cyclopentenone system afforded significant inhibition at 2.5 mg/kg/day (Hall et al. 1979). The sesquiterpene lactones were marginally effective against induced pleurisy. The delayed hypersensitivity was suppressed by these agents, whereas immunoglobulin synthesis was slightly stimulated. No deleterious side effects were observed with these agents from the limited tests performed. In a double-blind, placebo-controlled 6-week study of 40 female patients with symptomatic rheumatoid arthritis, no apparent benefit of oral feverfew administration and placebo was found in rheumatoid arthritis (Patrick et al. 1989). No important differences between the clinical or laboratory variables of the groups were observed.

Antinociceptive cum Antiinflammatory Activity

Oral administration of the feverfew extract led to significant, dose-dependent antinociceptive and antiinflammatory effects against acetic acid-induced writhing in mice and carrageenan-induced paw oedema in rats, respectively (Jain and Kulkarni 1999). Parthenolide (1, 2 mg/kg i.p.), the active constituent of the extract, also produced antinociceptive and antiinflammatory effects. Naloxone, an opiate antagonist, failed to reverse feverfew extract and parthenolide-induced antinociception. Feverfew extract in higher doses (40, 60 mg/kg p.o.) neither altered the locomotor activity nor potentiated the pentobarbitone-induced sleep time in mice. It also did not change the rectal temperature in rats.

The study showed that feverfew extract exerted antinociceptive and antiinflammatory effects without altering the normal behaviour of the animals.

Analgesic Activity

Parthenolide showed significant analgesic activity (about 85–90 % of the activity of paracetamol) as evaluated by acetic acid-induced writhing in mice, followed by the alcoholic extracts of flowers and leaves (about 55 and 45 % of the activity of paracetamol, respectively) (Rateb et al. 2007). The significant analgesic activity was attributed to the presence of high concentration of sesquiterpene lactones, especially parthenolide, and flavonoids.

Antipyretic Activity

Parthenolide showed significant antipyretic activity (about 60–70 % of the activity of acetyl salicylic acid (ASA)), followed by the alcoholic extracts of flowers and leaves which showed significant antipyretic activity (40–55 % of ASA activity) in the yeast-induced hyperthermia test (Rateb et al. 2007).

Antispasmodic Activity

In animal studies, feverfew extract inhibited collagen-induced bronchoconstriction by inhibiting phospholipase A2 activity (Keery and Lumley 1986). Samples prepared from chloroform extracts of fresh feverfew leaves strongly inhibited responses of rabbit aortic rings to phenylephrine, 5-hydroxytryptamine, thromboxane mimetic U46619 (9,11-dideoxy-11 alpha,9 alpha-epoxy-methano-PGF2 alpha) and angiotensin II indicating a nonspecific, most likely post-receptor site of action, but weakly inhibited contractions induced by potassium depolarization (Barsby et al. 1991, 1992). The inhibition was concentration and time dependent, noncompetitive and irreversible and also occurred in

endothelium-denuded preparations. The feverfew extracts also caused a progressive loss of tone of pre-contracted aortic rings and appeared to impair the ability of acetylcholine to induce endothelium-dependent relaxations of the tissue. Similar effects were demonstrated by parthenolide. They also found that chloroform extracts of feverfew leaf contain an as yet unidentified substance capable of producing a selective, open-channel block of voltage-dependent potassium channels in smooth muscle cells (Barsby et al. 1993a). They also found that fresh feverfew leaf extracts differing radically in their content of α -methylbutyrolactones caused time-dependent, irreversible inhibition of the contractile responses of rabbit aortic rings to all receptor-acting agonists so far tested (Barsby et al. 1993b). The presence of potentially -SH reactive parthenolide and other sesquiterpene α -methylenebutyrolactones in these extracts, and the close parallelism of the actions of pure parthenolide, suggested that the inhibitory effects were due to these compounds. Contrariwise, chloroform extracts of dried powdered leaves were not inhibitory but themselves elicited potent and sustained contractions of aortic smooth muscle that were not antagonized by ketanserin (5-HT₂ receptor antagonist). These extracts were found not to contain parthenolide or butyrolactones. They concluded that the marked differences in the pharmacological potency and profiles between preparations from fresh and dried feverfew may be related to their lactone content.

Of all the extracts and major constituents, the alcoholic flower extract exhibited the most potent antispasmodic activity in the isolated rabbit duodenum, producing prolonged inhibition of intestinal motility, followed by the leaf extract (Rateb et al. 2007). Parthenolide produced moderate but not complete inhibition even at its high dose. All the aqueous extracts produced spasmogenic effect by increasing intestinal motility. Parthenolide, a sesquiterpene α -methylenebutyrolactone obtained from feverfew, inhibited smooth muscle contractility in a time-dependent, nonspecific and irreversible manner (Hay et al. 1994). They found that the characteristic smooth muscle inhibitory profile

was demonstrated by the two α -methylenebutyrolactones (parthenolide and cynaropicrin), but not by the compounds lacking this functional group. Thus, the α -methylene function was critical for this aspect of the toxic pharmacological profile of the sesquiterpene butyrolactones. Béjar (1996) found that parthenolide inhibited the contractile responses of rat stomach fundus to fenfluramine and dextroamphetamine, but not serotonin. It inhibited serotonin release-mediated responses by the indirect-acting serotonin agonists on fundal tissue.

Antilcerogenic Activity

Parthenolide from feverfew was found to exert beneficial effects in experimental murine colitis (Zhao et al. 2012). Administration of parthenolide significantly reduced the severity of dextran sulphate sodium-induced colitis and downregulated myeloperoxidase activity and phospho-NF- κ B p65 expression by the blockade of phosphorylation and subsequent degradation of I κ B protein, strikingly reducing the production of TNF- α and IL-1 β .

Antimicrobial Activity

The essential oils from feverfew leaves, stems and roots showed inhibitory effects on *Escherichia coli* and *Salmonella typhi* but were inactive against *Staphylococcus aureus* (Shafaghat et al. 2009). Essential oil from herbal parts of feverfew from two different locations, Davutpasa-Istanbul and Savşat-Ardahan, exhibited antibacterial activity (Polatoglu et al. 2010). The oil from Davutpasa-Istanbul showed highest activity against *Bacillus subtilis* (125 μ g/ml) and methicillin-resistant *Staphylococcus aureus* (125 μ g/ml) and was characterized by camphor 49 %, *trans*-chrysanthenyl acetate 22.1 % and camphene 9.4 %. The oil from Savşat-Ardahan showed highest activity against *Staphylococcus aureus* (125 μ g/ml) and had 60.8 % camphor and 6.8 % camphene, small amount of *cis*-chrysanthenyl acetate (0.6 %) and trace amount

of *trans*-chrysanthenyl acetate. All the oils showed toxicity to *Vibrio fischeri* in the TLC bioluminescence assay. DPPH scavenging activity was 59.3 % of the oil from Davutpasa-Istanbul at 15 mg/ml concentration and 28.2 % for the oil from Savşat-Ardahan. Feverfew essential oil exhibited antibacterial activity against *Bacillus subtilis* and *Enterobacter aerogenes*, with the minimum inhibitory concentration of 4 and 38 µl/ml, respectively (Mohsenzadeh et al. 2011).

Antimitotic/Antimutagenic Activities

Anderson et al. (1988) compared the frequency of chromosomal aberrations and sister chromatid exchanges in lymphocytes and urine mutagenicity in two groups of migraine patients chronic feverfew users ($n=30$) and matched nonusers ($n=30$). They found the mean frequency of chromosomal aberrations in the feverfew user group was lower than that in the nonuser group both in terms of cells with breaks (2.13 % vs. 2.76 %) and in terms of cells with all aberrations (4.34 % vs. 5.11 %), although the difference was not significant. Similarly the sister chromatid exchanges in the feverfew exposed group were lower than that in the control group (8.78 vs. 8.80 SCE/cell), but this difference was not significant.

Of the flavonoids isolated from *T. parthenium* extract showing activity as mitotic blocker, centaureidin 1 had an IC_{50} of 1 µM, while jaceidin 2 and santin 3 were 200 times less active (Long et al. 2003).

Antileishmanial Activity

Parthenolide, from *T. parthenium*, exhibited significant in-vitro activity against the promastigote form of *Leishmania amazonensis*, with 50 % inhibition of cell growth at a concentration of 0.37 µg/ml (Tiuman et al. 2005). For the intracellular amastigote form, parthenolide reduced by 50 % the survival index of parasites in macrophages when it was used at 0.81 µg/ml. The purified parthenolide showed no cytotoxic effects against

J774G8 macrophages in culture and did not cause lysis in sheep blood when it was used at higher concentrations that inhibited promastigote forms. A guaianolide 11,13-dehydrocompressanolide purified from the hydroalcohol extract of aerial parts of feverfew showed activity against the promastigote form of *Leishmania amazonensis*, with 50 % inhibition (IC_{50}) of cell growth at a concentration of 2.6 µg/ml (da Silva et al. 2010). For the intracellular amastigote form, this guaianolide reduced by 10 % the survival index of parasites in macrophages when it was used at 20 µg/ml. The selective index (SI) ratio (CC_{50} for J774G8 cells/ IC_{50} for protozoans) was 385, showing that it was more selective against the parasite than mammalian cells.

Trypanocidal Activity

Trypanocidal activity against epimastigote forms of *Trypanosoma cruzi*, by feverfew crude extracts, fractions and parthenolide, was observed (Izumi et al. 2008). The pure parthenolide showed $IC_{50}/96$ hours and $IC_{90}/96$ hours of 0.5 µg/ml and 1.25 µg/ml, respectively. The cytotoxic effect of parthenolide in LLMCK2 cells was 3.2 µg/ml ($CC_{50}/96$ hours) and the selectivity index was 6.4. No hemolysis was detected for parthenolide. The internalization index of *T. cruzi* in LLMCK2 cells was reduced almost 51 % at the concentration of 2 µg/ml of parthenolide and 96.6 % at 4 µg/ml. A guaianolide (11,13-dehydrocompressanolide) isolated from *Tanacetum parthenium* was shown to be effective against *Trypanosoma cruzi*, with IC_{50} values of 18.1 and 66.6 µM against the multiplicative epimastigote and amastigote forms, respectively (Cogo et al. 2012). The best results were obtained against trypomastigotes, with an EC_{50} of 5.7 µM. The guaianolide presented no toxicity in LLMCK₂ cells (CC_{50} of 93.5 µM) and was 16.4-fold more selective for trypomastigotes. The study of the combinational effect of benznidazole and guaianolide revealed the presence of a synergistic effect against the epimastigote form and marginal additive effect against the trypomastigote form.

Toxicity Studies

Feverfew, with up to 4 mg of parthenolide, given daily as an oral tablet, was well tolerated without dose-limiting toxicity by patients with cancer but did not provide detectable plasma concentrations (Curry et al. 2004). Because of this, parthenolide pharmacokinetics was not able to be completed and was warranted especially with administration of higher doses of purified parthenolide. Feverfew is traditionally contraindicated in pregnancy, and studies by Yao et al. (2006) confirmed this warning. They found that female rats fed orally with 839 mg/kg feverfew daily on either gestation days (GD) 1–8 or 8–15 had adverse effects. Preimplantation loss appeared increased but this was not statistically significant in the feverfew GD1–8 group. Foetuses exposed to feverfew from GD8–15 were smaller than ethanol controls. Feverfew induced toxicity when GD10.5 rat embryos were cultured for 26 hours in rat serum to which feverfew extract was added. They suggested the need for a comprehensive reproductive study of feverfew.

Allergic Dermatitis Problem

Hausen (1981) reported a case of a 40-year-old female florist developed recurrent dermatitis of the face, neck, hands and forearms after a half-year handling of a new ornamental form of feverfew. Epicutaneous tests revealed positive reactions to 10 species of the Compositae family, including chrysanthemums, aster *Gaillardia*, *Arnica* and true chamomile. However, the strongest results were seen with petals and leaves of feverfew. A case of specific, delayed hypersensitivity induced by repeated contact with a wild form of feverfew (*Tanacetum parthenium*) was reported (Hausen and Osmundsen 1983). In the flowers investigated the content of the responsible contact allergen parthenolide appeared to be ten times greater (0.6–0.9 %) than in earlier years. Guinea pig experiments confirm the strong sensitizing potency of feverfew. Cross-reactions were elicited with 11 of 21 mostly Asteraceae plants containing chemically related

sesquiterpene lactones. In a study of Compositae dermatitis, out of 686 patients tested with the sesquiterpene lactone mix and 79 with the Compositae mix, a total of 31 Compositae-sensitive patients (4.5 %) were found (Paulsen et al. 1993). Testing with the individual ingredients of the Compositae mix showed frequent positive patch test reactions to feverfew, followed in order by chamomile, tansy, yarrow and arnica.

In further studies, patch testing with constituents of sesquiterpene lactone (SL) mix, Compositae mix (CM) and other Compositae extracts and allergens in 190 Compositae-allergic patients was detected in an 8-year period (Paulsen et al. 2001). Feverfew of CM elicited positive reactions most frequently, followed by tansy, wild chamomile, yarrow and arnica, whereas dehydrocostus lactone of SL was the most frequent elicitor of positive reactions, followed by alantolactone and costunolide. In a study of chrysanthemum dermatitis among florists and amateur gardeners in South Wales, Schmidt and Kingston (1985) found that diagnosis could be conducted by patch testing with feverfew extract as all patients reacted to the feverfew extract.

Studies using a high-volume air sampler revealed that no particle-bound parthenolide was released from flowering *Tanacetum parthenium* plants (Christensen et al. 1999). Among volatiles emitted from the aerial parts of feverfew plants and collected by the dynamic headspace technique, a total of 41 compounds, mainly monoterpenes, were identified and quantified in ng; α -pinene (680.6 ng), camphene (2149.2 ng), limonene (314 ng), γ -terpinene (280.9 ng), (*E*)- β -ocimene (941.9 ng), *p*-cymene (2,247 ng), (*E*)-chrysanthenol (1,299 ng), camphor (4845.5 ng), (*E*)-chrysanthenyl acetate (2856.2 ng), (*E*)- β -caryophyllene (284.1 ng), linalool (211.7), β -farnesene (319.5 ng) and α -farnesene (251.6 ng) were the predominant monoterpenes accounting for nearly 89 % of the total volatiles emitted. The average total yield of volatiles emitted over 24 hours was 18,160 ng/g fresh weight of leaves and flowers, corresponding to the emission of approximately 8 mg volatiles per day from one full-grown feverfew plant. No parthenolide or other sesquiterpene lactones

were detected. The results did not support the theory of airborne sesquiterpene lactone-containing plant parts or of direct release of sesquiterpene lactones from living plants as the only explanations for airborne Compositae dermatitis. In another study on airborne Compositae dermatitis, of the 17 persons with + +/+ + + reactions to feverfew and parthenolide tested, 13 had positive and/or doubtful positive reactions to 1 or more monoterpenes (Paulsen et al. 2002). Only one person was allergic to several monoterpenes. Her history of gradually worsening Compositae dermatitis culminating in a probable airborne dermatitis, mimicking photosensitivity and the disappearance of symptoms upon removal of feverfew plants suggested monoterpenes as a possible contributing factor. Similar associations between doubtful positive monoterpene reactions and clinical patterns, fragrance/colophonium allergy and relevance of feverfew allergy were not established with certainty. The authors concluded sensitization to the sesquiterpene lactones of feverfew was not invariably accompanied by sensitization to its volatile monoterpenes, but the presence of monoterpene allergy, however, may contribute to airborne Compositae dermatitis.

The results of a clinical study of 12 feverfew-allergic patients confirmed that some feverfew-allergic patients were sensitive to airborne particles released from feverfew, and isolation of parthenolide from the particle-containing high-volume air sampler extract in allergenic amounts provided strong evidence of parthenolide as the responsible allergen (Paulsen et al. 2007). Out of seven patients with feverfew contact allergy who were patch tested with two creams containing the feverfew extract four of the patients tested positive to one of the creams; reactivity was associated with simultaneous positive reactions to parthenolide (Paulsen et al. 2010). This cream was analysed about 2 years later, and no parthenolide was detected, probably because of degradation of the compound.

Two cases of Compositae dermatitis exacerbated by moisturizer containing feverfew were reported in two women (Killoran et al. 2007). Patient 1 had a + reaction to sesquiterpene lactone mix, a + reaction to Compositae mix, a + reaction

to parthenolide, a + reaction to *Tanacetum vulgare* and a + reaction to the calming moisturizer. Patient 2 had + reactions to sesquiterpene lactone, Compositae mix and the same calming moisturizer.

Traditional Medicinal Uses

Feverfew has a long history of use in traditional folkloric medicine among Greek and early European herbalists. Since the 1980s, feverfew has become a highly popular British, French and Canadian phytomedicine used to prevent migraine headaches, relieve menstrual cramps and treat painful joints (Awang 1989, 1997). Feverfew has been traditionally used for a wide range of ailments including psoriasis, toothache, migraine headache, insect bites, rheumatism, rheumatoid arthritis, vertigo, colic, allergies, asthma, tinnitus, dizziness, nausea, vomiting, stomach pain, menstrual problems, inflammation, fever, infertility, problems with menstruation and labour during childbirth and cleansing the kidneys and bladder (Hobbs 1989; Groenewegen et al. 1992; Pareek et al. 2011). The roots and rhizomes of feverfew have been used in Iranian traditional medicine under the name of 'Aqhovan', as digestive and stomachic tonic (Mojab et al. 2007). Medieval monastic healers used it as an antipyretic (Berry 1984; de Pooter et al. 1989). A tea made from the whole plant is used in the treatment of arthritis, colds, fevers, migraine headaches, etc. and is said to be sedative and to regulate menses (Bown 1995; Foster and Duke 1998). However, pregnant women and lactating mothers are advised not to take feverfew (Awang 1993; Yao et al. 2006). The herb is applied externally as a tincture to treat bruises (Grieve 1971). An infusion of the herb is used to bathe swollen feet (Moerman 1998). Chewing 1–4 leaves per day has been used as a remedy for migraine (Foster and Duke 1998). The leaves and flower heads are deemed to be antiinflammatory, antispasmodic, aperient, bitter, carminative, emmenagogue, sedative, stimulant, astringent, stomachic, vasodilator and vermifuge (Grieve 1971; Chiej 1984; Mills 1985).

Other Uses

The dried flower buds are a source of an insecticide and are said to have similar properties to pyrethrum. The plant was also planted in house gardens to keep malaria at bay. An essential oil from the plant is used in perfumery.

Comments

Feverfew was called 'parthenium' by the ancient Greeks based on the myth that the plant was used to medically save the life of someone who had fallen from the Parthenon, during its construction in the fifth century BC; Parthenon was the Doric temple of the virgin goddess Athena on the Acropolis in Athens (Hobbs 1989).

Origin/Distribution

Tanacetum vulgare is of Eurasian origin, but was widely introduced globally and to North America where it became invasive in some areas (Wolf et al. 2012).

Agroecology

Tansy is a cool climate species. In its native and nonnative range, it occurs from near sea level to 1,600 m elevation in woodlands, meadows, rangeland, prairies, alpine grassland, montane steppe, marshes, mires, disturbed sites, gardens, pastures, railroads, roadsides, irrigation ditches, stream banks, river banks and lake shores. It is adaptable to a wide range of soil types. It can be found in dry soils, nutrient-poor soils and loamy and sandy soils to heavy, wet or moist soils but thrives in nutrient-rich, moist, well-drained soils. It occurs in sites with full sun to partial shade.

Edible Plant Parts and Uses

The young leaves and flowers are edible (Fernald et al. 1958; MacNicol 1967; Larkcom 1980; Facciola 1990; Harris 1995). Young aromatic

leaves finely chopped are used in salads, puddings, cakes, biscuits, fritters, fish dishes, etc. Leaf juice has been used to flavour omelettes known as tansies. Crushed tansy leaves have been used to flavour whiskey. Tansy cheese is made by steeping the herb and pouring the extract into milk before curdling. The plant is also used as a flavouring substitute for nutmeg and cinnamon. Leaves and flowering tops are brewed into a bitter lemon-flavoured tea. Flowers have unique flavour eaten and are used for garnishing.

Botany

A robust, herbaceous perennial with erect, distally branched stems reaching 50–150 cm high (Plates 1 and 2). Leaves alternate, basal cauline, petiolate or sessile, lamina oval to elliptic in outline, 5–25 cm by 2–10 cm wide, pinnately lobed with 4–10 pairs of primary elliptic–lanceolate

Plate 1 Tansy herb

Plate 2 Tansy foliage

Plate 3 Corymbiform array of flowering heads (T. James)

Plate 4 Close-up of flowering heads of Tansy (T. Candresse)

lobes and dentate margins, surfaces sparsely hairy or glabrous, gland dotted (Plates 1 and 2). Flowering heads, axillary and terminal (Plate 5), numerous in corymbiform pattern, each head compact, oblate, flat topped, yellow, with more than 100 individual florets. Involucre 5–10 mm across, receptacle convex to conic (Plates 3 and 4). Ray florets disciform, outer ones pistillate, corolla 3–4 lobes, yellow. Disc florets with 2–3 mm yellow corolla. Achene 1–2 mm, 4–5-angled or ribbed, gland-dotted with crown-toothed pappus.

Plate 5 Axillary and terminal flowering heads (J. Holopainen)

Nutritive/Medicinal Properties

Sesquiterpene lactones tanacetin, β -hydroxyarbusculin A and reynosin were isolated from *T. vulgare* by Samek et al. (1973). Yunusov et al. (1979) isolated the following sesquiterpene lactones from the dried aerial parts: chrysanin, tamarin, tanachin and tavulin. Tanavulgarol, an oxygenated sesquiterpene, was isolated from *T. vulgare* (Chandra et al. 1987b). Two germacranolides and an *n*-decyl glucoside were isolated from the aerial parts (Chandra et al. 1987a). Four flavonoids were isolated from tansy flowers: tilianin, acacetin, cosmosiin and apigenin (Kurkina et al. 2011) besides luteolin, cinaroside, eupatilin, jaceidin and jaceoside reported earlier by the main author Kurkina. The flavonoids 6-hydroxyluteolin 6,3'-dimethyl ether (jaceosidin) and quercetagenin 3,6,3'-trimethyl ether (jaceidin) had been reported from the flowers of *T. vulgare*

(Ivancheva et al. 1998). The following flavonoids were detected in *T. vulgare* leaves: flavones (scutellarein-6-methyl ether (hispidulin), scutellarein-6-4'-dimethyl ether (pectolarigenin), luteolin, 6-hydroxyluteolin 6-methyl ether (nepetin), 6-hydroxyluteolin 6,3'-dimethyl ether (jaceosidin)) and flavonols (quercetagenin-3-methyl ether, quercetagenin 3,6-dimethoxy ether (axillarin), quercetagenin 3,6,3'-trimethyl ether (jaceidin)) (Ivancheva et al. 1998).

Some wild tansy plants were found to produce 80–90 % β -thujone, whereas others gave the normal content (70–85 %) of α -isothujone throughout the growing season (Von Rudloff and Underhill 1965). Significant variations in the content of the minor components were found to occur only in very young plants, when appreciable amounts of ϵ -, γ - and δ -cadinene and an unidentified labile (possibly C_5) alcohol were detected.

Three tansy chemotypes were identified from tansy specimens growing in the province of Eastern Flanders (Belgium): the β -thujone, *trans*-chrysanthenyl acetate and camphor/ β -thujone types (De Pooter et al. 1989). The essential oil content of Hungarian samples of *Tanacetum vulgare* varied from 0.02 to 0.66 % and exhibited a heterogeneous distribution of chemotypes (Tétényi et al. 1975). Twenty-six different chemotypes were found. Individuals and populations containing artemisia ketone and umbellulone as their main components were the most frequent. The following compounds were identified in the essential oils of five *Tanacetum vulgare* genotypes: artemisia alcohol, γ -campholenol, davanone, lyratol, lyratyl acetate and 4-thujen-2 α -yl acetate (Héthelyi et al. 1981). The essential oil from clone 409 of *Tanacetum vulgare* from Hungary was found to contain *trans*-chrysanthenyl acetate (75 %) and *trans*-chrysanthenol (5–10 %) (Neszmélyi et al. 1992).

The strained tricyclic sesquiterpene ketones vulgarone A and longipin-2-en-1-one (vulgarone B) were isolated as constituents of *Chrysanthemum vulgare* essential oil (Uchio et al. 1976, 1977; Uchio 1978). Vulgarone B was transformed into vulgarone A via a sigmatropic shift in the laboratory by irradiation with UV light. The essential oil of tansy from Eastern Kazakhstan was found

to contain >50 components out of which 39 were identified (Dembitskii et al. 1984). The oil contained a substantial amount of α -thujone (19 %), artemisia ketone and *L*-camphor (12 %), while δ -terpinenol-4, (-)-borneol, bornyl acetate, neryl acetate, α -terpineol, carvone, achillenol (santolina alcohol), camphor, β -thujone, nerol geraniol, filipendulol (epichrysanthenol) and thymol were present in small amounts. The terpene hydrocarbon fraction included α -pinene (1.0 %), achillene (1.5 %), camphene (1.5 %), β -pinene, sabinene, β -myrcene, limonene, β -phellandrene, 1,8-cineole (3.0 %), γ -terpinene, *p*-cymene and terpinolene. Sesquiterpene hydrocarbons were present in an amount of 1.1 %. Among them were ylangene, longicyclene, γ -elemene, *p*-gurgunene, β -elemene, β -caryophyllene, β -selinene, δ -cadinene, γ -cadinene, α -curcumene, 8-cadinene, calamenene and calacorene. The plant belonged to the thujone chemotype. Tansy genotypes in Finland were distributed among eight 'well-defined' main groups: sabinene, thujone, umbellulone, camphor, bornyl acetate, α -pinene, 1,8-cineole and germacrene D (Holopainen et al. 1987). The sesquiterpene germacrene D was identified for the first time in the present study in the essential oil of tansy. Most of these 'well-defined chemotypes' were again divided into subgroups A and B. In addition to the 'well-defined chemotypes', a number of 'mixed chemotypes' were also detected in the crossings. Those chemotypes accounted for 20 % of the whole crossing material tested.

Essential oil from aerial parts of *T. vulgare* plant from 'Tierra del Fuego' (Argentina) afforded β -thujone (91.65 %) as the major constituent (Gallino 1988), thus indicating that the plant belonged to the thujone chemotype. Some minor components included sabinene, 1,8-cineole, α -thujone, germacrene D, terpinen-4-ol, γ -terpinene, *p*-cymene, pinocarvone, sabinol, eugenol and unidentified sesquiterpene alcohol. Traces of α -pinene, β -pinene, α -terpinene, α -terpineol, terpinolene, limonene, unidentified sesquiterpene hydrocarbon, myrtenol, myrcene, umbellulone and carvacrol were also found. Major constituents *T. vulgare* essential oils included camphor, isopinocampheol, *trans*-chrysanthenyl acetate, sabinene, bornyl acetate and germacrene

D (Hendriks et al. 1989). Tansy leaf oil in Holland was found to contain bicyclogermacrene trace, bornyl acetate 0.9 %, camphene 1.40 %, camphor 9.4 %, β -caryophyllene 0.7 %, 1,8-cineole 0.4 %, *p*-cymene 0.4 %, germacrene D 6.50 %, α -pinene 0.3 %, β -pinene trace, sabinene 3.9 %, sabinene hydrate 0.4 %, terpinene-4-ol 0.4 %, α -terpinene 0.3 %, γ -terpinene 0.3 %, α -thujone 0.9 % and β -thujone 67.9 % (Hendriks et al. 1990).

An investigation of 14 samples of Tansy occurring in the northeastern part of the Netherlands revealed the presence of an artemisia ketone, a chrysanthenol/chrysanthenyl acetate, a lyratol/lyratyl acetate and a β -thujone chemotype (Hendriks et al. 1990). The essential oils of the flower heads contained a higher percentage of the main constituent than the oil obtained from the leaves. Vulgarone A and B were detected in five samples; however, vulgarone A was only found in the leaf oils. *Cis*-longipinane-2, 7-dione, a component of Bulgarian Tansy, could be detected only in two samples. Examination of the essential oils and extract of tansy plant occurring in the Chicoutimi area (Quebec) revealed several chemotypes (Collin et al. 1993). Half of the plants belong to a camphor-1,8-cineole-borneol (concentration >52 %) mixed chemotype. The β -thujone chemotype (>60 %) was also present in six samples. Four specimens of a chrysanthemone type (>50 %) were also observed. Finally, one sample showed a high concentration of dihydrocarvone (>60 %). A commercial sample produced in the vicinity of Quebec City belonged mainly to the β -thujone chemotype. A small population of *T. vulgare* was found to comprise three pure chemotypes based on the sesquiterpene lactones: only germacranolides, only eudesmanolides and no sesquiterpene lactones (Todorova and Ognyanov 1999). Mixed chemotypes were not identified because probably these pure chemotypes were unable to produce hybrids. Of the 20 constituents identified in the essential oil from the aerial parts of *Tanacetum vulgare* from India, six were monoterpene hydrocarbons (3.9 %), 10 oxygenated monoterpenes (81.9 %), one sesquiterpene hydrocarbon (1.7 %), two phenolic compounds (3.0 %) and a long-chain hydrocarbon (1.5 %) (Charles et al. 1999). The oil belongs

to the thujone (66.8 %) chemotype. (+)-10 Hydroxy-3-thujone was characterized from the oil. Tansy genotypes in Finland were distributed among eight 'well-defined' main groups: sabinene, thujone, umbellulone, camphor, bornyl acetate, α -pinene, 1,8-cineole and germacrene D (Holopainen et al. 1987). The sesquiterpene germacrene D was identified for the first time in the present study in the essential oil of tansy. Most of these 'well-defined chemotypes' were again divided into subgroups A and B. In addition to the 'well-defined chemotypes', a number of 'mixed chemotypes' were also detected in the crossings. Those chemotypes accounted for 20 % of the whole crossing material tested.

A total of 55 volatile compounds were detected, and 53 were identified in the air-dried flower heads of 20 Finnish tansy genotypes (Keskitalo et al. 2001). Fifteen genotypes were well defined and five were mixed chemotypes. The most frequently encountered monoterpene was camphor with or without several satellite compounds such as camphene, 1,8-cineole, pinocamphone, chrysanthenyl acetate, bornyl acetate and isobornyl acetate. In 13 genotypes, camphor concentration exceeded 18.5 %, and in seven genotypes, camphor was less than 7.2 %. Other chemotypes rich in *trans* thujone, artemisia ketone, 1,8-cineole or davadone D were also identified. Davadone-D and a mixed chemotype, containing tricyclene and myrcene, were identified from a Finnish tansy for the first time. Geographically, most chemotypes containing camphor originated from Central Finland, whereas chemotypes without camphor such as artemisia ketone, davadone D and myrcene-tricyclene originated from South or Southwest Finland. The group comprising the highest concentration of camphor chemotypes had the tallest shoots. The groups with chemotypes containing davadone-D or artemisia ketone, which originated from Southwest Finland, produced the most number of flower heads, had the tallest corymb and were last to flower. Also, the group consisting from chemotypes with a high concentration of camphor and originated from South Finland exhibited late flowering.

Forty-one constituents were identified in the essential oils from inflorescences and leaves of

tansy grown in Vilnius district (Lithuania), and the oils were distributed among four chemotypes (Mockute and Judzentiene 2004). The major constituents of the camphor chemotype (10 samples) were camphor (22.3–41.4 %) and 1,8-cineole (10.6–26.4 %); the α -thujone chemotype (six samples) was found to be dominated by α -thujone (25.7–71.5 %) and 1,8-cineole (11.3–22.3 %); the major constituents of the 1,8-cineole-chemotype (three samples) was dominated by 1,8-cineole (24.5–32.7 %) and camphor (8.3–23.8 %); and the artemisia ketone chemotype (one sample of inflorescences) predominantly featured artemisia ketone (30.5 %) and camphor (23.0 %). The oil from inflorescences of the above chemotypes contained higher amounts of the first major component and oxygenated monoterpenes (mean 83.6 %) than the leaf oils (mean 73.7 %). An opposite correlation was noticed for mono- and sesquiterpene hydrocarbons and oxygenated sesquiterpenes.

The yield of essential oils of tansy plants from 40 different locations in North, Mid- and South Norway ranged between 0.35 and 1.90 % (v/w) (average: 0.81 %); the most abundant thujone plants were especially rich in essential oil volatiles (0.95 %) (Rohloff et al. 2004). Seven chemotypes could be identified as follows: (A) α -thujone (two individuals), (B) β -thujone (22), (C) camphor (six), (D) chrysanthenyl acetate/chrysanthenol (three), (E) chrysanthenone (two), (F) artemisia ketone/artemisia alcohol (three) and (G) 1,8-cineole (two). The thujone chemotype was dominated by β -thujone (81 %) associated with α -thujone, but tansy plants rich in α -thujone were also detected (61 %). Tansy genotypes in Norway could be grouped into the following chemotypes: the mixed chemotypes Steinvikholmen (thujone–camphor), Alvdal (thujone–camphor–borneol), Goldsticks (thujone–camphor–chrysanthenyl type) and Brumunddal (thujone–camphor–1,8-cineole–bornyl acetate/borneol– α -terpineol) and the distinct chemotype Richters, with average concentrations of (E)-chrysanthenyl acetate >40 % in both leaf and flower essential oil (Dragland et al. 2005). The essential oil of *Tanacetum vulgare* leaves from Perú was characterized by a high amount of β -thujone (87.83 %), and belonged to the thujone chemotype (De La Cruz et al. 2008).

Altitude, geographical, temperature gradient, as well as soil-climate conditions were found to impact on the essential oil composition of *T. vulgare* (Vaverková et al. 2006). In the lowest-lying locality with a relatively large sunshine, the content of β -thujone in the essential oil was the highest, whereas in the regions lying towards the north, the content of the essential oil was decreased and the content of camphor was increased. In the northernmost region of Slovakia, an increased number of chemovars of the camphor–cineole type was observed. The following compounds were identified in *T. vulgare* essential oil in Slovakia: α -pinene, camphene, sabinene, β -pinene, myrcene, 1,8-cineole, artemisia ketone, β -thujone, camphor, borneol, umbellulone, D-carvone, chrysanthenyl acetate, bornyl acetate, thymol, germacrene and carvacrol (Mikulášová and Vaverková 2009).

Ninety-four components were detected in the essential oils from aerial parts and capitula of *Tanacetum vulgare* subsp. *siculum* (Formisano et al. 2009). Alpha-thujone, β -thujone and 1,8-cineole were the main constituents. Based on the chemical profile, this *Tanacetum* species was assigned to the thujone chemotype. Five known sesquiterpene lactones with the eudesmane skeleton, douglanin, ludovicin B, ludovicin A, 1 α -hydroxy-1-deoxoarglanine and 11,13-dehydrosantonin, were isolated from the flowers of a subspecies of *T. vulgare* in Sicily (Rosselli et al. 2012). This *T. vulgare* species can be assigned to the eudesmanolide chemotype.

The water-soluble pectin complex from tansy flowers was found to consist of four different polysaccharide fractions (Yakovlev and Sysoeva 1983). Polysaccharide I contained 64 % of D-galacturonic acid and the neutral monosaccharides (PC, GLC), galactose, glucose, arabinose, xylose and rhamnose in a quantitative ratio of 5:3:3:1:4. Polysaccharide II contained 20 % of galacturonic acid and the neutral monosaccharides (PC, GLC) galactose, glucose, arabinose, xylose and rhamnose in a quantitative ratio of 10:8:3:1:2. Polysaccharide (III) contained 30 % of a uronic acid and the neutral monosaccharides galactose, glucose, arabinose, xylose and rhamnose in a quantitative ratio of 9:5:2:1:4. Polysaccharide (IV) contained 18 % of uronic acid and the neutral

monosaccharides galactose, glucose, arabinose, xylose and rhamnose in a quantitative ratio of 8:7:2:1:1.

Tanacetan TVF, isolated from floccules of tansy, was found to be a branched pectic polysaccharide with backbone of linear α -1,4-d-galacturonan (Polle et al. 2002). The ramified regions appeared to be rhamnogalacturonan-I with core of α -1,2-L-rhamno- α -1,4-d-galacturonan. The side sugar chains were attached by 1,4-linkages to the L-rhamnopyranose residues of the core and consist of single residues of β -galactopyranose and β -1,4-galactopyranan with branching points of 4,6-substituted β -d-galactopyranose residues. In addition, the branching regions contained the side chains of a branched α -1,5-arabinofuranan bearing 2,5- and 3,5-substituted α -L-arabinofuranose residues as the branching points. Some side chains of rhamnogalacturonan appeared to represent arabinogalactan, containing the branched sugar chains of α -1,5-arabinofuranan attached to the linear chains of β -1,4-galactopyranan by 1,3- and 1,6-linkages. The residues of α -L-arabinofuranose appeared to occupy the terminal positions of the arabinogalactan side chains. Four acidic polysaccharide fractions (designated T-I to T-IV) were isolated and purified from Tansy florets (Xie et al. 2007). The average *Mr* of fractions T-I through T-IV was estimated to be 326, 151, 64 and 9 kDa, respectively. Tansy polysaccharides consisted primarily of galacturonic acid, galactose, arabinose and rhamnose. Fractions T-II through T-IV contained an arabinogalactan type II structure.

β -Sitosterol was found as the major sterol and α -amyrin as the major triterpene of tansy (Chandler et al. 1982). Other sterols identified included stigmasterol, campesterol and cholesterol, and the triterpenes identified included β -amyrin, taraxasterol and pseudo-taraxasterol. *Cis*-longipinane-2,7-dione, a sesquiterpene diketone, was isolated from the flowers (Ognyanov et al. 1983). Two nonvolatile sesquiterpene alcohols designated tanacetol A, $C_{17}H_{26}O_4$, ketol sesquiterpene and tanacetol B, $C_{19}H_{30}O_5$, its monoacetyl derivative, were isolated from *T. vulgare* (Calleri et al. 1983; Appendino et al. 1983). Fifteen sesquiterpene lactones and a sesquiterpene alcohol were isolated from *T. vulgare*

plant: (tatridin A, tatridin B, tanachin (=deacetyldihydrochrysanolide, 1-*epi*-tatridin B), tamarin (=deacetylchrysanolide), parthenolide, costunolide diepoxide, anhydroverlotrin 4 α ,5 β -epoxide, artemorin, artemorin 4 α ,5 β -epoxide, the eudesmanolides 1-*epi*-ludovicin C (=armexifolin), armefolin, 1 β -hydroxyarbusculin A, reynosin, santamarin and magnolialide) and the germacrene derivative tanacetol B (Sanz and Marco 1991).

The vacuolar flavonoids of both *Tanacetum parthenium* and *T. vulgare* were dominated by the presence of apigenin and luteolin 7-glucuronides; nine other glycosides were present, including the uncommon 6-hydroxyluteolin 7-glucoside in *T. vulgare* (Williams et al. 1999). The surface flavonoids of *T. vulgare* were methyl ethers of the flavones scutellarein and 6-hydroxyluteolin. Total phenolic contents reported for *T. tanacetum* (leaf) was 1.68 mg GAE/100 g DW (Wojdyło et al. 2007). Major phenolic compounds (mg/100 g DW) found were phenolic acids (894 mg caffeic acid, 335 mg neochlorogenic acid, 471 mg ferulic acid) and flavonoids (848 mg luteolin, 165 mg apigenin). Polyphenolic compounds (g/kg dry matter) in the aerial tansy plant parts were determined as follows: chlorogenic acid 4.12 g, 3,5-DCQA (dicaffeoylquinic acid) 11.82 g, 4,5, DCQA 3.54 g, total caffeoyl derivatives 19.49 g, total dihydroxycinnamic acid derivatives 41.53 g, total flavonoids 11.40 g, total dihydroxycinnamic acid derivatives + flavonoids 52.93 and total polyphenolic compounds 65.86 g (Fraisse et al. 2011).

Constituents of fresh tansy plant oil grown in two localities Ada Huja (green area) and Topčider (industrial, polluted area) in Belgrade, Serbia, respectively were as follows: α -phelandrene trace, 0.6 %; *p*-cumene trace, 0.5 %; β -phelandrene trace, 0.5 %; santolina alcohol 1.7, trace; linalool oxide trace, 1.7 %; artemisia ketone 1.1 %, 0.7 %; sabinene hydrate trace, 0.8 %; undecane 2.7 %, trace; α -thujone 0.9, trace; β -thujone 8.3 %, 1.3 %; pinocarvone 0.8 %, trace; *p*-cresol acetate trace, 0.8 %; *cis*-pinochamphone trace, 2.8 %; *trans*-carveol acetate 5.1 %, 14.5 %; piperitone 0.9 %, 3.1 %; linalool oxide acetate 0.8 %, 9.9 %; germacrene D 1.1 %, trace; *trans*-chrysanthanol trace, 1.4 %; spathulenol 5.5 %, trace; *trans*-chrysanthenyl acetate 47.9 %, 36. %; longiborneol

0.9 %, trace; and α -cadinol 3 %, trace, total 80.7 %, 75.5 % (Stevovic et al. 2011).

The biosynthesis of monoterpene ketone, (-)-camphor, a major constituent of *T. vulgare* essential oil, was reported by Croteau and Shaskus (1985). They demonstrated a geranyl pyrophosphate: (-)-bornyl pyrophosphate cyclase in soluble enzyme preparations from immature tansy leaves converted the acyclic precursor [1-3H]geranyl pyrophosphate to the bicyclic monoterpene alcohol borneol in the presence of $MgCl_2$ and oxidized a portion of the borneol to camphor in the presence of a pyridine nucleotide. The biosyntheses of irregular monoterpene artemisia ketone, the regular monoterpenes camphor and β -thujone, the sesquiterpene germacrene D, the diterpene *trans*-phytol and β -sitosterol and isofucosterol were studied in axenic cultures of *Tanacetum vulgare* (Umlauf et al. 2004). It was found that the isoprene units of the monoterpenes and the diterpene were formed via the methylerythritol phosphate (MEP) pathway, whereas the isoprene building blocks of the sesquiterpene and the sterols originated from the mevalonic acid (MVA) pathway.

Antioxidant Activity

Antioxidant activity in terms of TEAC (μM trolox/100 g DW) of *T. vulgare* leaves reported was 37.3 μM for ABTS, 469 μM for DPPH and 455 μM for FRAP (ferric reducing antioxidant power) assays (Wojdyło et al. 2007). The crude methanol extract of Tansy aerial parts displayed DPPH radical scavenging effects with an EC_{50} value of 37 $\mu g/ml$ (Juan-Badaturuge et al. 2009). Three antioxidant compounds, 3,5-*O*-dicaffeoylquinic acid (3,5-DCQA), axillarin and luteolin, were isolated. 3,5-DCQA was the major constituent with antioxidant activity ($IC_{50}=9.7 \mu M$) comparable with that of the standard quercetin ($IC_{50}=8.8 \mu M$). Total antioxidant capacity (%) (DPPH scavenging activity) of tansy aerial plant parts was 7.42 %, and contribution from the main caffeoyl derivatives was as follows: chlorogenic acid 5.66 %, 3,5-DCQA (dicaffeoylquinic acid) 19.1 %, 4,5-DCQA

5.88 % and total caffeoyl derivatives 31.35 % (Fraisie et al. 2011).

Anticancer Activity

T. vulgare was one of several Asteraceae species that exhibited antileukaemic properties against J-45.01 human acute T leukaemia cell line and induced death via apoptosis (Wegiera et al. 2012). Five sesquiterpene lactones isolated from the flowers, douglanin, ludovicin B, ludovicin A, 1 α -hydroxy-1-deoxoarglanine and 11,13-dehydro-santonin, exhibited cytotoxic activity in-vitro on A549 (human lung carcinoma epithelial-like) and V79379A (Chinese hamster lung fibroblast-like) cells using the tetrazolium salt reduction (MTT) assay (Rosselli et al. 2012). Studies by Fang et al. (2010) found that parthenolide could markedly enhance sensitivity of human lung cancer A549 cells to low-dose oxaliplatin by inhibiting NF-kappaB/p65, COX-2 and PGE(2) activation and inducing apoptosis. Parthenolide in combination with a low dose of oxaliplatin may be a beneficial chemotherapeutic strategy for patients who cannot tolerate the severe side effects of the drug at therapeutic concentrations.

Antiviral Activity

Aqueous tansy extract was found to partially inactivate in tick-borne encephalitis (TBE) virus (Fokina et al. 1991). In-vivo studies revealed that tansy extract could induce resistance of mice to TBE virus infection assessed by the increased survival rate of the animals and significant prolongation of the average longevity. Parthenolide, isolated from aerial parts of *Tanacetum vulgare*, protected Vero cells from herpes simplex virus (HSV-1) infection in-vitro (Onozato et al. 2009). The extract and parthenolide exhibited anti-HSV-1 activity with an EC_{50} of 40 $\mu g/ml$ and 0.3 $\mu g/ml$, respectively, in the sulforhodamine B colorimetric assay. It was found that parthenolide interfered with virus replication after the penetration stage, inhibiting approximately 40 % of plaques formed at a concentration of 2.5 $\mu g/ml$

when compared with an untreated control. The anti-HSV-1 activity of tansy aerial parts, ethyl acetate extract and the isolated compound parthenolide, had been reported recently, and it was revealed that constituents other than parthenolide were responsible for the antiviral activity of tansy (Alvarez et al. 2011).

Antimicrobial Activity

Tansy exhibited some degree of antimicrobial activity in-vitro against both Gram-positive and Gram-negative bacteria and some fungi (Holopainen and Kaupinnen 1989; Holetz et al. 2002). Microorganisms susceptible to a hydroalcoholic extract of *T. vulgare* included *Bacillus subtilis*, *Escherichia coli* and *Pseudomonas aeruginosa*. Anticandidal activity against *Candida krusei* and *C. tropicalis* was also observed. In another study, all 5 samples of *T. vulgare* essential oils were found inhibitory to *Bacillus subtilis*, one sample (T1) was inhibitory to *Micrococcus luteus* and another sample T3 was the best, inhibiting growth of *Escherichia coli*, *Bacillus subtilis*, *Proteus mirabilis*, *Staphylococcus aureus* and also *Candida albicans* (Mikulášová and Vaverková 2009). MIC of *T. vulgare* essential oils for all bacteria ranged from <0.6 % to >>2.5 %. Samples T4 and T5 exerted the lowest antibacterial effect.

Antiinflammatory Activity

Tansy chloroform leaf extract administered intraperitoneally (i.p.) inhibited in a dose-dependent way the carrageenan-induced paw oedema in rats; the calculated ED₅₀ was 15.2 (7.6–30.4) mg/kg (Mordujovich-Buschiazzi et al. 1996). The extract also inhibited the subchronic inflammation induced by Freund's adjuvant in doses ranging from 80 to 160 mg/kg i.p. The major flavonol and flavone methyl ethers of both *Tanacetum parthenium* and *T. vulgare* plants variously inhibited the major pathways of arachidonate metabolism in leucocytes (Williams et al. 1999). There were significant differences in potency, with the

tansy 6-hydroxyflavones less active than the feverfew 6-hydroxyflavonols as inhibitors of cyclooxygenase and 5-lipoxygenase. From the moderately lipophilic fractions of tansy plant were isolated the active principles responsible for the antiinflammatory activity of tansy against the mouse ear oedema induced by 12-*O*-tetradecanoylphorbol 13-acetate (Schinella et al. 1998). Parthenolide caused 93 % oedema inhibition at 0.5 mg/ear, with an ID₅₀=0.18 µmol/ear, and the methoxyflavones jaceosidin, eupatorin, chrysoeriol and diosmetin caused 80 % oedema inhibition at 0.5 mg/ear, ID₅₀=0.50 µmol/ear. The potency of parthantienolide was nearly three times greater than that of the most active of the flavones due to its more abundant amount in the plant.

Immunotherapeutic Activity

High *Mr* polysaccharide fractions T-I and T-II isolated from tansy flowers exhibited potent macrophage-/monocyte-activating activity, enhancing production of reactive oxygen species (ROS), nitric oxide (NO) and tumour necrosis factor alpha (TNF-α) by J774.A1 murine macrophages and activating nuclear factor κB (NF-κB) in THP-1 human monocytes (Xie et al. 2007). In addition, Tansy polysaccharides stimulated human neutrophil function by greatly enhancing neutrophil myeloperoxidase (MPO) release. Further, the low *Mr* fraction T-IV had potent complement-fixing activity, which may also contribute to the antiinflammatory and wound healing properties of Tansy extracts. The results elucidated at least part of the beneficial therapeutic effects of Tansy extracts and support the concept of using Tansy polysaccharides as an immunotherapeutic adjuvant.

Vasorelaxant Activity

In-vitro studies on the contractile response of Wistar rat aorta to high KCl and noradrenaline and on endothelium-dependent relaxation evoked by acetylcholine indicated that the

aqueous tansy extract exerted NO-mediated and NO-independent vasorelaxing properties (Lahlou et al. 2008b).

Antiulcerogenic Activity

Yakovlev and Sysoeva (1983) reported that an earlier pharmacological study had shown that the polysaccharide complex from tansy flowers exhibited antiulcer action in rats with various types of experimental gastric ulcers. Gastric ulcers induced by oral administration of absolute ethanol to rats were reduced dose-dependently by oral pretreatment of animals with the tansy chloroform extract (2.5–80 mg/kg) or its major constituent parthenolide (5–40 mg/kg) (Tournier et al. 1999). When administered 30 minutes before ethanol challenge, the protection ranged between 34 and 100 % for the extract and 27 and 100 % for parthenolide. When administered 24 hours before ethanol insult, 40 mg/kg of the extract and of the parthenolide reduced the mean ulcer index from 4.8 for control animals to 1.4 and 0.5, respectively. Administration of both products before ethanol treatment restored the numbers of mucosal -SH groups to values near those found for normal animals.

Diuretic Activity

Oral administration of the aqueous extracts of caraway seeds and tansy leaves to male Wistar rats significantly increased urine output at all time points (Lahlou et al. 2007). Both plant extracts increased urinary levels of Na⁺ and K⁺, to about the same extent, while furosemide, the reference drug, increased urinary levels of only Na⁺ and decreased urinary K⁺. In the 8-day sub-chronic study, all three substances induced significant diuresis and natriuresis; only tansy increased urinary potassium excretion. The results indicated that the water extracts of both *Carum carvi* and *Tanacetum vulgare* possessed strong diuretic action confirming their ethnopharmacological use.

Migraine Prophylactic Activity

T. parthenium samples established from seeds from ten different regions were found to vary significantly within and between samples in migraine prophylactic activity in-vitro (Marles et al. 1992). Serotonin release inhibition from bovine platelets was found to correlate significantly with the content of germacranolide sesquiterpene lactone, parthenolide, although other sesquiterpene lactones from this plant and other Asteraceae species (including *T. vulgare*) were also shown to be active.

Immunomodulating Activity

The acetone leaf extracts of *T. parthenium* and *T. vulgare* inhibited phorbol myristate acetate-induced chemiluminescence of human polymorphonuclear leucocytes, with IC₅₀s from 0.79 to 2.46 mg leaf dry weight/ml whole blood (Brown et al. 1997). Parthenolide concentration in *T. parthenium* was high, 1.72 % leaf dry weight, but lower in *T. vulgare*, 0.03 %. Fractionation of crude leaf extracts revealed a number of fractions, in addition to those containing parthenolide, which influenced polymorphonuclear leucocyte activity by >5 %. The effects on phorbol myristate acetate-induced chemiluminescence suggested the activity of the responsible compound(s) was a result of inhibition of protein kinase C, or subsequent events, in polymorphonuclear leucocyte activation in-vitro.

Insect Repellency Activity

A small-scale experiment confirmed the mosquito-repellent activity of *T. vulgare*, without allowing the identification of the active principle (De Pooter et al. 1989). However, the activity was much lower than that of diethyltoluamide containing commercial preparation.

The volatiles of the essential oils of tansy flower heads and the fractions exhibited strong tick (*Ixodes ricinus*) repellency (90–100 %) (Pålsson et al. 2008). Main volatiles detected from oils of

T. vulgare collected at Uppsala were α -pinene (27 %), β -pinene (11 %), pinocamphone (11 %), 1,3,3-trimethylcyclohex-1-ene-4-carboxaldehyde (11 %) and 1,8-cineole (10 %). In the sample collected in Stockholm, the main components were β -thujone (39 %) and camphor (23 %) followed by α -thujone (11 %) and 1,8-cineole (8 %). When constituents in the oils, e.g. α -terpineol, 4-terpineol, α -thujone, β -thujone, 1,8-cineol, verbenol and verbenone, were tested separately (each diluted 0.5 %, vol:vol), 64–72 % tick repellency was obtained.

Allergic Dermatitis Problem

Prolonged exposure to tansy may cause allergic contact dermatitis (Hausen and Oestmann 1988). The leading Compositae species with sensitizing properties was found to be the chrysanthemum. Most of the reactions obtained with other Compositae species such as arnica, marguerite, sunflower, tansy and yarrow were interpreted as cross-reactions due to the fact that cross-reactivity predominates within the sesquiterpene lactone constituents of the various Compositae species. In a study of 25 patients known or suspected to be allergic to different Compositae plants, 1 patient elicited positive epicutaneous reaction to tansy (Hausen 1979). Cross-reactions of patient were seen to tansy [14], yarrow [11], chamomile [10], arnica and sunflower [5]. In further studies, patch testing with constituents of sesquiterpene lactone (SL) mix, Compositae mix (CM) and other Compositae extracts and allergens in 190 Compositae-allergic patients were detected in an 8-year period (Paulsen et al. 2001). Feverfew of CM elicited positive reactions most frequently, followed by tansy, wild chamomile, yarrow and arnica, whereas dehydrocostus lactone of SL was the most frequent elicitor of positive reactions, followed by allantolactone and costunolide.

Toxicity and Toxicological Studies

According to the dispensatory of the United States of America, tansy had been used to a

considerable extent as a domestic abortifacient, but was also very dangerous in its action, and had in various cases produced death (Osol and Farrar 1955). The symptoms caused included abdominal pain, vomiting, violent epileptic convulsions often followed by profound coma, dilated pupils, great disturbances of respiration, frequent and feeble pulse, and death, which had been said to be from heart failure but was probably the outcome of a paralytic asphyxia. A fluidrachm (3.75 mils) of the oil was reported to have caused death. Tansy tea had also caused death.

In the acute study in mice, the crude aqueous extract of tansy leaves caused dose-dependent adverse general behaviour effects and mortality (Lahlou et al. 2008a). The no-observed-adverse-effect levels (NOAEL) of the tansy extract were 7.0 and 1.0 g/kg, and the lowest-observed-adverse-effect levels (LOAEL) were 9.0 and 1.5 g/kg, when administered by the oral and intraperitoneal routes, respectively. Mortality increased with increasing doses, with LD₅₀ of 9.9 and 2.8 g/kg for the oral and intraperitoneal modes of administration, respectively. In the chronic study in rats, daily oral administration of the crude aqueous extract of tansy leaves for up to 90 days did not result in death or significant changes in the biological (except for hypoglycaemia) and haematological parameters. Based on the high NOAEL values in the acute study in mice and lack of significant effect on biological and haematological parameters in rats after 90 days of daily doses, the authors concluded the tansy extract did not appear to have significant toxicity. Further in view of the dose of tansy consumed in traditional medicine, there appeared to be a wide margin of safety for the therapeutic use of the aqueous extract of *Tanacetum vulgare* leaves.

Traditional Medicinal Uses

For several past centuries, tansy has been commonly used as a domestic medicinal herb for treating a wide range of ailments, though it is less

commonly used in modern herbalism (Grieve 1971; Bown 1995; Chevallier 1996; Alvarez et al. 2011). The leaves and flowering heads are anthelmintic, antispasmodic, bitter, carminative, emmenagogue, stimulant, antihypertensive, diuretic and tonic. Tansy is principally used in traditional Moroccan medicine as antihypertensive remedy (Lahlou et al. 2008a; Stevovic et al. 2011). A decoction of tansy flowers and fruit is an effective agent for expelling roundworms, pinworms and tapeworms and is also used in jaundice, as a sedative in cases of rheumatism, headache and epilepsy (Dembitskii et al. 1984). Bitter tea made from the flowering heads is commonly used as an effective vermifuge for intestinal infestations especially in children and to a lesser extent to help stimulate menstrual flow. Seeds are also anthelmintic. Tansy tea or an infusion is also used as a remedy for ulcers, constipation, fever, diabetes, rheumatism, jaundice and hysteria. Common tansy in large doses has been used to induce abortion but in smaller doses was thought to prevent miscarriage and increase fertility. Tansy is also used in face wash to lighten, tonify and purify skin. Externally, tansy is also used as a poultice on swellings and some eruptive skin diseases. It is also used externally to kill lice, fleas and scabies. Tansy has also been used as an embalming substitute for corpses by early US settlers.

Other Uses

Tansy has insecticidal property. In the olden days before refrigeration, tansy foliage was used to cover meat to repel flies. Tansy is commonly used as a strewing herb in cellars, churches, etc., in order to repel insects. Both foliage and essential oil have been used to kill fleas and flies. The steam distillate of fresh leaves and flowers of tansy was found to be strongly repellent to the Colorado potato beetle, *Leptinotarsa decemlineata* (Schearer 1984). Fifty-six compounds were detected; camphor (30 %) and umbellulone (25 %) were the major components. A commercial tansy oil was also found to be highly repellent to Colorado beetles; the major component was bornyl acetate 74 %. Other components

with strong repellency included 1-8-cineole, *p*-cymene, γ -terpinene and camphor. Colorado potato beetle, *Leptinotarsa decemlineata*, exhibited avoidance behaviour to tansy oil, volatiles from intact tansy plants, a 'hydrocarbon fraction' of tansy oil, obtained by fractionation on alumina, and five of the 13 known components of tansy oil (Panasiuk 1984). α -Terpinene, thujone, dihydrocarvone and carvone produced definite avoidance behaviour in Colorado potato beetles, and to a slightly lesser degree, γ -terpinene had the same effect. One constituent of tansy oil, α -pinene, attracted the beetle.

When tansy essential oil was continuously present at 0.1 and 1 % in the diet, all oblique-banded leaf-roller (OBLR) larvae from susceptible and resistant populations died (Larocque et al. 1999). The presence of 0.01 % tansy essential oil in the diet affected female pupal weight, but not larval weight gain, larval developmental time and male pupal weight. Residues of the formulation TE (tansy essential oil, ethanol 95 %) deterred oviposition of *Choristoneura rosaceana* female. The DSD (direct steam distillation) and DW (distillation in water) extracts of *T. vulgare* were more toxic (75.6 and 60.4 % mite mortality, respectively, at 4 % concentration) to the two-spotted spider mite, *Tetranychus urticae*, than the MAP (microwave-assisted process) extract (16.7 % mite mortality at 4 % concentration) (Chiasson et al. 2001). Chemical analysis of the *T. vulgare* extracts indicated that β -thujone was by far the major compound of the oil (>87.6 %) and probably contributed significantly to the acaricidal activity of the oil. Thujone is an effective insecticide, but it is highly toxic to mammals when taken in excess (Bown 1995).

A green dye is obtained from the foliage and yellow dye from the flowers and leaves. The plant also made good compost materials.

Comments

This species varies greatly in terpene composition, forming different chemotypes (Wolf et al. 2012). Refer also to the chapter on *Tanacetum parthenium*.

Agroecology

In its native range and introduced areas in warm subtemperate and temperate zones, dandelion occurs wild in lawns, on roadsides, on disturbed banks and shores of water ways, on disturbed sunny areas, on fields, on grasslands and on other areas with moist soil from near sea level to 1,000 m elevation. It also occurs in the tropics in the cool highlands at altitudes of 1,200–1,500 m. It is a hardy plant, drought and frost tolerant, tolerating temperatures down to -29°C . It will grow in all types of soil from sandy dunes, well-drained, humus-rich alkaline to neutral soils to thick clays including crevices in rocks and stones and brackish habitats. It grows in full sun or partial shade. *T. officinale* is considered a weedy species found in ruderal sites, lawns and grassy places.

Edible Plant Parts and Uses

The flowers, flower buds, leaves, leaf stalks, roots and sprouted seeds are edible (MacNicol 1967; Grieve 1971; Harrington 1974; Halpin 1978; Facciola 1990; Roberts 2000). The unopened flower buds while still inside the crown are eaten in pancakes, omelettes, schnapps and fritters; they can also be preserved in vinegar and used like capers. When serving a rice dish, dandelion petals are used like confetti over the rice. The young, freshly picked flowers are added to salad for colour and flavour or fried with bacon. Some recipes include dandelion flower omelette, dandelion and bacon and dandelion and beetroot salad (Roberts 2000). The flowers are used as an ingredient in the Arabic cake 'yublo'. The flowers can be made into dandelion flower jam. Mature flowers are bitter. Dandelion flowers have traditionally been used to make dandelion wine, for which there are numerous recipes. Flowers have also been used in a saison ale called 'Pissenlit' in Belgium. The flowers, leaves and roots are brewed into pleasant teas. The sprouted seeds are edible and used in salads.

Origin/Distribution

Dandelion is native to Europe and Asia Minor; it is now cosmopolitan—distributed worldwide in temperate and subtemperate areas—and is becoming a noxious weed.

Young leaves are eaten in salads, boiled like spinach, blanched steamed, sautéed, fried or braised or cooked in soups. Blanched leaves make an excellent salad either alone or in combination with other vegetables lettuce, shallot tops or chives. The blanched leaf stalks or crown can be eaten raw or as a cooked vegetable. In Vietnam, leaves are used fresh like lettuce, or boiled, made into soup, or fried like other vegetables. The young leaves make delicious sandwiches, placed between slices of bread and butter and sprinkled with salt; the addition of pepper and lemon juice varies the flavour. Dried dandelion leaves are also used as an ingredient in many digestive or diet drinks and herb beers. Dandelion beer is a rustic fermented drink common in England and Canada. Dandelion herbal beer is less intoxicating than ordinary beers, and dandelion stout ranks as a favourite. An agreeable and wholesome fermented drink can be made from dandelions, nettles and yellow dock. The roots are eaten raw or cooked and served like salsify. The roots are roasted to make dandelion coffee, a very good coffee substitute. Dandelion coffee is a natural coffee without the narcotic effects of coffee or tea. The ground roots can be mixed with coffee or chocolate and brewed.

Botany

Perennial small herb to 40 cm high with long, unbranched, tuberous tap root and milky latex. Leaves 1–20, horizontal or ascending, arranged spirally in a radical rosette; lamina—oblanceolate, 6–40 cm long by 0.7–15 cm wide, irregularly pinnatilobed to pinnatipartite, variably pubescent or glabrous, almost distinctly petiolate or tapering into a winged petiole, petiole green often tinged purplish (Plates 1 and 3). Inflorescence an axillary head, 1–25 per plant on a hollow, leafless, hairy peduncle, outer involucre bracts multiseriate, patent to recurved, ovate to lanceolate, unequal without horns (thickened clawed apices), inner involucre bracts 1-seriate, erect, oblong, receptacle flat. Florets 40 to over 100 per head, bisexual, homogamous ligulate, with yellow or

Plate 1 Dandelion plant habit

orange-yellow corollas, five stamens with anthers fused to a tube, ovary inferior with one ovule, style greenish or yellowish with two spreading stigmas (Plates 1, 2 and 3). The fruits called cypselae are narrowly obovoid, 3 mm long, ribbed, olive-green or olive-brown to straw coloured to greyish in colour, with slender beaks crowned by a scabrid, silky white pappus.

Nutritive/Medicinal Properties

Plant/Aerial Parts Phytochemicals

Cadosh et al. (1978) isolated flavoxanthin and chrysanthemaxanthin from the plant. The aerial parts afforded a new eudesmanolide, a tetrahydrodridentin B, a eudesmanolide- β -D-glucopyranoside and two germacranolide acids, which were esterified with B-D-glucose (Hansel et al. 1980). Scopoletin and esculetin were isolated from the

Plate 2 Dandelion lowers on long slender peduncles

Plate 3 Close view of dandelion flower and leaves

aerial parts (Komissarenko and Derkach 1982). The herb is also rich polysaccharides (primarily fructosans and inulin) and contains smaller quantities of pectin, resin and mucilage and various flavonoids (Rutherford and Deacon 1972; Cordatos 1999). Cichoric acid and the related monocaffeoyltartaric acid were found to be the major phenolic constituents in flowers, roots, leaves and involucre bracts and also in the medicinal preparations tested (Williams et al. 1996).

Volatile metabolites from suspension cultures of *Taraxacum officinale* identified included acetic acid butyl ester, 2-methyl-1-propanol, *n*-butyl alcohol, 4-phenyl-1-butanol, 4-hydroxy-4-methyl-2-pentanone, acetic acid, 4-terpineol, β -terpineol and α -terpineol (Hook et al. 1991). Undifferentiated cultured cells and plants of *Taraxacum officinale* were found to contain oleanolic and ursolic acids as major triterpenoids

in addition to triterpenols composed mainly of α - and β -amyrins, taraxasterol and lupeol, and negligible quantities of triterpene acids (Akashi et al. 1994). Squalene synthase activity was detected in the microsomal fractions of suspension-cultured cells of dandelion which produced cycloartane (involved in phytosterol biosynthesis) and other classes (e.g. oleanane and ursane) of triterpenoids (Komine et al. 1996). Purple-coloured dandelion callus cultures produced anthocyanin pigments when established on a cytokinin-rich medium under the light (Akashi et al. 1997). The major pigment was identified as cyanidin 3-(6''-malonylglucoside). Chalcone synthase (CHS) activity was detected in the extracts of these purple cells. Dandelion (*T. officinale*) plant was found to contain triterpenes produced by cyclization of oxidosqualene such as taraxasterol, taraxerol, lupeol, α -amyrin and β -amyrin (Masaaki et al. 2006). cDNA cloning of triterpene synthase yielded ten cDNA clones: cycloartenol synthase (TRX), lupeol synthase (TRW), BETA-amyrin synthase (TRY), taraxerol synthase (TRT), achilleol synthase (TRA), simiarenol synthase (TRE), three multifunctional triterpene synthase (TRH, TRR and TRN) and putative oxidosqualene cyclase (TRV).

Field-grown dandelion plants accumulated higher contents of polyphenolic acid compounds (mg/g dw) than hydroponic grown plants: total phenolic acids (31.2 mg vs. 5.00 mg), cichoric acid (26.5 mg vs. 3.82 %), chlorogenic acid (0.95 % vs. 0.43 %) and caftaric acid (3.75 % vs. 0.75 %), respectively (Pedneault et al. 2002). Polyphenolic compounds (g/kg dry matter) in the aerial dandelion plant parts were determined as follows: chlorogenic acid 0.84 g, cichoric acid 34.08 g, total caffeoyl derivatives 43.92 g, total dihydroxycinnamic acid derivatives 53.92 g, total flavonoids 1.62 g, total dihydroxycinnamic acid derivatives + flavonoids 55.54 g and total polyphenolic compounds 53.59 g (Fraisie et al. 2011).

The phytochemicals in various parts of the plant included ascorbic acid, caffeic acid, calcium, magnesium, potassium, chlorogenic acid, luteolin, K, isoquercetin and mannitol (Duke 2005); major sesquiterpene lactones, generally occurring as glycosides (sugars), taraxacosides, taraxacolides,

dihydrolactucin, ixerin, taraxinic acids and ainslioside (Schütz et al. 2006a); and phenylpropanoids (cinnamic acid derivatives)—cichoric acid, monocaffeoyltartaric acid, 4-caffeoylquinic acid, chlorogenic acid, caffeic acid and inulin (Schütz et al. 2006b). *Taraxacum officinale* was found to be rich in triterpenoid and sterol bitter principles (principally taraxacin and taraxacerin) which were found to be distributed uniformly in the roots, leaves and flowers (Sharafzadeh 2011). Other triterpene compounds included triterpenoids such as oleanolic and ursolic acids, and triterpenols such as lupeol, β -amyrin, α -amyrin, taraxasterol and taraxerol, as well as free phytosterols such as sitosterin, stigmasterin and phytosterin.

Leaf Nutrients and Phytochemicals

Nutrient composition of fresh raw dandelion greens (*Taraxacum officinale*) per 100 g edible portion was reported as follows (UDSDA 2012): water 85.60 g; energy 45 kcal (188 kJ); protein 2.70 g; total lipid (fats) 0.70 g; ash 1.80 g; carbohydrate 9.20 g; fibre (total dietary) 3.5 g; minerals (Ca 187 mg, Fe 3.10 mg, Mg 36 mg, P 66 mg, K 397 g, Na 76 mg, Zn 0.41 mg, Cu 0.171 mg, Mn 0.342 mg and Se 0.5 μ g); vitamins (vitamin C (ascorbic acid) 35 mg, thiamine 0.190 mg, riboflavin 0.260 mg, niacin 0.806 mg, pantothenic acid 0.084 mg, vitamin B-6 0.251 mg, folate (total) 27 μ g, vitamin A 10161 IU, vitamin E (α -tocopherol) 3.44 mg and vitamin K (phylloquinone) 778.4 μ g); β -carotene 5,854 μ g, α -carotene 363 μ g, β -cryptoxanthin 121 μ g and lutein+zeaxanthin 13,610 μ g; total unsaturated fatty acids 0.170 g (14:0 (myristic acid) 0.009 g, 16:0 (palmitic acid) 0.145 g and 18:0 (stearic acid) 0.007 g); total monounsaturated fatty acids 0.014 g, 18:1 (oleic acid) 0.014 g; and total polyunsaturated fatty acids 0.306 g, 18:2 undifferentiated (linoleic acid) 0.261 g and 18:3 undifferentiated (linolenic acid) 0.044 g.

Dandelion is a very nutritious vegetable, rich in protein, fibre and minerals like Ca, Fe, P and K, especially K, vitamin C, vitamin A, β -carotene, α -carotene, β -cryptoxanthin, lutein and zeaxanthin. It is also a good source for vitamin E, vitamin K,

folate, pantothenic acid, vitamin B-6 and vitamin Bs.

The elemental content of Br, Cu, Mn and Pb in the leaves correlated with the extent of anthropogenic pollution of the region where the plant developed (Djingova et al. 1986). A positive linear correlation was observed between the Cu and Pb, Cu and Sb, Pb and Cd, and Pb and Zn content of the leaves. The leaves had been reported to contain considerable amount of furan fatty acids (Hannemann et al. 1998).

Sitosterol (about 60 %) was the most abundant free sterol, followed by stigmasterol (25 %), then campesterol (10 %) in dandelion leaves (Westerman and Roddick 1981). Cholesterol could not be detected. With the exception of stigmasterol and campesterol, esters were present in greater quantities than were free forms, with 4,4-dimethyl sterol esters being the most abundant and principal type comprising cycloartenol (about 40 %) and 24-methylene cycloartenol (about 30 %) and 4-demethyl forms being less abundant. Of the latter, sitosterol ester was present in largest amount (about 25 % of total esters) followed by stigmasterol ester (about 1.5 %) and trace amounts of campesterol ester appearing sporadically. β -Amyrin and β -sitosterol were extracted from dandelion leaves by supercritical fluid extraction (SFE) (Simándi et al. 2002). Soxhlet extraction with *n*-hexane gave yield and recoveries of the active components similar to SFE. Among the investigated methods, extraction with ethyl alcohol resulted in the highest extraction yield and yields of β -amyrin and β -sitosterol.

A sesquiterpene fungitoxin, lettucenin, A was isolated from the leaves treated after stressing with cupric chloride (Tahara et al. 1988). Three flavonoid glycosides (luteolin 7-glucoside and two luteolin 7-diglucosides), hydroxycinnamic acids, cichoric acid, monocaffeoyltartaric acid and chlorogenic acid, coumarins, cichoriin and esculin were identified in the leaf extracts (Williams et al. 1996). Esculin, cichoriin, caftaric acid, cichoric acid and mixtures of various esters of these compounds were isolated from the leaves of *T. officinale* (Budzianowski 1997). Cichoric acid and chlorogenic acid were isolated from dandelion leaves (Chkhikvishvili and

Kharebava 2001). Leaves of field-grown plants accumulated higher contents of polyphenolic acid compounds (mg/g dw) than the leaves of hydroponic grown plants: total phenolic acids (61.5 mg vs. 5.63 mg), cichoric acid (61 mg vs. 4.21 %), chlorogenic acid (0.58 % vs. 0.47 %), caftaric acid (8.95 % vs. 1.41 %), respectively (Pedneault et al. 2002). Dandelion leaves were found to be rich in triterpenes such as β -amyrin (7.920–13.750 g/100 g) and β -sitosterol (1.910–3.810 g/100g) (Kristó et al. 2003). A mammalian DNA polymerase inhibitor of D-mandelonitrile- β -D-glucoside (prunasin) was isolated from the acetone leaf extract (Mizushina et al. 2003). The dichloromethane extract of dandelion leaves afforded taraxasteryl acetate, lupeol acetate, taraxinic acid, 11,13-dihydrotaraxinic acid, phytyl fatty acid ester and squalene (Ragasa et al. 2009).

Flower/Seed Phytochemicals

The principal pigment found in dandelion flower extracts was a diester of taraxanthin designated taraxien (Booth 1964). The concentration in the flowers expressed as carotenol was about 350 ppm fresh weight. Appreciable amounts of the monoester and of free taraxanthin were found in the flowers. The monoester had solubilities and adsorption affinities between those of taraxien and taraxanthin.

Three flavonoid glycosides (luteolin 7-glucoside and two luteolin 7-diglucosides), free luteolin, chrysoeriol, hydroxycinnamic acids, cichoric acid, monocaffeoyltartaric acid and chlorogenic acid were isolated from dandelion flowers (Williams et al. 1996). All-E-lutein epoxide was the major carotenoid isolated from dandelion petals and that there were also high amounts of the (9Z)- and (9'Z)-isomers, although the latter may be an artefact (Meléndez-Martínez et al. 2006). Three antimicrobial peptides designated ToAMP1, ToAMP2 and ToAMP3 were purified from *Taraxacum officinale* flowers (Astafieva et al. 2012). The peptides were cationic and cysteine rich and consisted of 38, 44 and 42 amino acid residues for ToAMP1, ToAMP2 and ToAMP3, respectively.

Storage 2S albumin proteins were found in dandelion seeds (Odintsova et al. 2010).

Root Phytochemicals

The roots had been reported to be rich in taraxacin, a crystalline, bitter substance and inulin (24 %) and also to contain gluten, potash, gum and sugar and laevulin (Grieve 1971). An aryl acylamidase (aryl-acylamine amidohydrolase) which hydrolyzes the herbicide propanil (3',4'-dichloropropionanilide) was isolated from dandelion roots (Hoagland 1975). A serine proteinase named taraxalisin was isolated from *Taraxacum officinale* roots (Rudenskaya et al. 1998; Bogacheva et al. 1999). It was found to be a 67-kD glycoprotein containing 54 % carbohydrate; the N-terminal sequence of taraxalisin had 40 % of its residues identical to those of subtilisin. It hydrolyzed a chromogenic peptide substrate Glp-Ala-Ala-Leu-pNA optimally at pH 8.0. The substrate specificity of taraxalisin towards synthetic peptides and oxidized insulin B-chain was comparable with that of cucumisin from *Cucumis melo* and the subtilisin-like serine proteinase macluralisin from *Maclura pomifera*.

A predominant 18-kDa vegetative storage protein was found present in dandelion roots (Xu et al. 2000). A rapid decrease in temperature from 20 to 5 °C (cold shock) resulted in an increase in the relative amount of the 18-kDa protein transcript, but no change in the amount of the protein within the root. Conversely, a warm-shock treatment (the transfer of plants from 5 to 20 °C) caused a decline in the 18-kDa protein transcript and a decline in the quantity of the 18-kDa root protein. Defoliation and wounding at 5 °C both stimulated an increase in the 18-kDa protein transcript within 36 hours, but there was no change in protein amount.

Dandelion was found to contain large amounts of inulin (12–15 %) and oligofructans in its tap roots (Bacon and Eldeman 1951; Schütz et al. 2006a, b; Van Loo et al. 1995). Three β -fructofuranosidases, namely, an invertase and two hydrolases (A and B), were separated from the soluble protein extracted from dandelion

(Rutherford and Deacon 1972). The hydrolases acted on the inulin series of oligosaccharides found in the roots. Dandelion roots were found to contain fructooligosaccharides (glucose, fructose, sucrose) and fructopolysaccharides (kestoses, nystose, fructofuranosylnystose) (Schütz et al. 2006b). The contents of kestose, nystose and fructofuranosylnystose in dandelion root exceeded that of artichoke.

Olennikov et al. (2009) found that fructose, glucose, saccharose, 1-kestose and nystose were present in the free state in dandelion roots. Two dominant polymeric glucofructan compounds, TGf-1 (5.7 kDa) and TGf-2 (2.6 kDa), which were linear inulin-type macromolecules consisting of fructofuranose units bonded through β -(2 \rightarrow 1)-bonds, were also found. TGf-1 had the structure $\text{Glc}p\text{-}1\text{-(}2\text{-Frcf-}1\text{)}_{32}\text{-}2\text{-Frcf}$, and TGf-2 had the following: $\text{Glc}p\text{-}1\text{-(}2\text{-Frcf-}1\text{)}_{12}\text{-}2\text{-Frcf}$.

Dandelion roots yielded a new eudesmanolide, a tetrahydridentin B, a eudesmanolide- β -D-glucopyranoside and two germacranolide acids, which were esterified with β -D-glucose (Hansel et al. 1980). All three of the new glucose derivatives had a strong bitter taste. An acylated γ -butyrolactone glycoside, taraxacoside, was isolated from the roots (Rauwald and Huang 1985). Its structure was elucidated as β -O-[4-O-(*p*-hydroxyphenylacetyl)- β -D-glucopyransoyl]- β -hydroxy- γ -butyrolactone. The hydroxycinnamic acids, cichoric acid, mono-caFFEoyltartaric acid, and chlorogenic acid were isolated from the roots (Williams et al. 1996). A triterpene, 3 β -hydroxylup-18(19)-ene-21-one was isolated from the roots (Kisiel et al. 2000). Five germacrane- and guaiane-type sesquiterpene lactones, including two previously described taraxinic acid derivatives, were isolated from the roots, together with benzyl glucoside, dihydroconiferin, syringin and dihydrosyringin (Kisiel and Barszcz 2000). The other three lactones were identified as 11 β , 13-dihydrolactucin, ixerin D and ainslioside. Further, the stereochemistry at C-11 in dihydrotaraxinic acid was assigned. Roots of field-grown plants accumulated higher contents of polyphenolic acid compounds (mg/g dw) than the roots of hydroponic-grown plants: total phenolic acids (9.8 mg vs. 1.23 mg), cichoric acid (7.82 mg vs.

0.96 %), chlorogenic acid (1.08 % vs. 0.1 %) and caftaric acid (0.9 % vs. 0.18 %), respectively (Pedneault et al. 2002). Sesquiterpene glucosides 14-O- β -D-glucosyl-11,13-dihydro-taraxinic acid and 14-O- β -D-glucosyl-taraxinic acid were isolated from the roots (Kashiwada et al. 2001). Dandelion roots were found to be rich in phytosterol content, e.g. β -sitosterol (1.498–2.109 g/100 g) and triterpenes β -amyirin (8.938–24.540 g/100 g) (Kristó et al. 2003). Among the 43 compounds (phenolic acids and flavonoids) detected in dandelion root and herb juice, 5 mono- and dicaffeoylquinic acids, 5 tartaric acid derivatives and 8 flavone and 8 flavonol glycosides were characterized (Schütz et al. 2005). The predominant compound was cichoric acid (dicaffeoyltartaric acid). The study revealed that even more quercetin glycosides were found in dandelion than hitherto assumed. Also the presence of di- and triglycosylated flavonoids was found.

Five lupane type of triterpenoids, namely, 3 β -acetoxy-18 α ,19 α -epoxylupan-21 β -ol (1), 18 α , 19 α -epoxy-21 β -hydroxylupan-3-one (2), lup-18-ene-3,21-dione (3), lupa-18,21-dien-3 β -yl acetate (4) and (17*S*)-17,18-*seco*-lup-19(21)-ene-3, 18,22-trione (5), named officinatrione, were isolated from dandelion roots (Saeki et al. 2013).

Over the past four decades, pharmacological studies on the plant had revealed the presence of a diverse range of phytochemicals in the plant and emphasized on its diuretic, choleric, anti-inflammatory, antioxidative, anticarcinogenic, analgesic, antihyperglycaemic, anticoagulatory, demulcent, digestive stimulant, immunomodulatory, insulin stimulant, antiangiogenic and prebiotic effects (Schütz et al. 2006a; Yarnell and Abascal 2009).

Antioxidant Activity

Dandelion extracts diminished the enzymatically induced lipid peroxidation and reduced the cytochrome c with and without NADPH in a concentration-dependent manner in the microsomal fraction of the rat liver (Hagymási et al. 2000). Total antioxidant capacity (%) (DPPH

scavenging activity) of dandelion aerial plant parts was 6.38 %, and contribution from the main caffeoyl derivatives was as follows: chlorogenic acid 1.26 %, cichoric acid 68.96 % and total caffeoyl derivatives 70.22 % (Fraisie et al. 2011).

The water and ethyl acetate fractions of dandelion flowers exhibited free radical scavenging activities in a stable 2,2-diphenyl-1-picrylhydrazyl (DPPH) radical model and reduced the breakage of supercoiled DNA strand induced by both non-site-specific and site-specific hydroxyl radical (Hu and Kitts 2003). Both fractions also reduced the oxidation of structured phosphatidylcholine liposome induced by peroxy radical with the ethyl acetate fraction having greater affinity to scavenge peroxy radical than the water fraction. At low concentration, prooxidant activity of both fractions was observed in Cu^{2+} -induced structured liposome and hLDL oxidation models, thus indicating that the reducing power of the dandelion flower extract had resulted in generation of reactive cuprous ion. However, at high concentrations, the ethyl acetate did not promote oxidation in the presence of Cu^{2+} , suggesting that the free radical scavenging activity of this fraction was sufficient to minimize the potential oxidative mechanism attributed to the metal ion reducing activity associated with prooxidant activity. The dandelion flower extract was found to contain both luteolin and luteolin 7-glucoside which contributed to observed in-vitro antioxidant and Caco-2 cell cytotoxic activities. They also reported that luteolin and luteolin-7-*O*-glucoside at concentrations lower than 20 μM significantly suppressed the productions of nitric oxide and prostaglandin E2 (PGE2) in bacterial lipopolysaccharide-activated mouse macrophage RAW264.7 cells without introducing cytotoxicity (Hu and Kitts 2004). The inhibitory effects were further attributed to the suppression of both inducible nitric oxide synthase (iNOS) and cyclooxygenase-2 (COX-2) protein expression, and not reduced enzymatic activity. Similar suppression for both inducible enzymes was also found with the presence of dandelion flower extract, specifically, the ethyl acetate fraction of dandelion flower extract which contained 10 % luteolin and luteolin-7-*O*-glucoside. In further studies, they showed that the dandelion flower

extract possessed marked antioxidant activity in both biological and chemical models (Hu and Kitts 2005). Furthermore, the efficacy of the flower extract in inhibiting both reactive superoxide and hydroxyl radicals and nitric oxide was attributed to its phenolic content. Characteristics of chain-breaking antioxidants, such as extended lag phase and reduced propagation rate, were observed in the oxidation of linoleic acid emulsion with the addition of dandelion flower extract. DPPH-radical scavenging activity and a synergistic effect with α -tocopherol were attributed to the reducing activity derived from phenolic content of the flower extract. A significant and concentration-dependent, reduced nitric oxide production from arterial-lipopolysaccharide-stimulated mouse macrophage RAW264.7 cells was observed with the addition of the flower extract. Furthermore, peroxy radical-induced intracellular oxidation of RAW264.7 cells was inhibited significantly by the addition of the flower extract over a range of concentrations.

The ethanol dandelion plant extract showed a scavenging activity in the 1,1-diphenyl-2-picrylhydrazyl (DPPH) assay, a diminishing effect on intracellular reactive oxygen species (ROS) level (Jeon et al. 2008). *T. officinale* fruit extract was shown to have antioxidant activity and protected slices of cortex, hippocampus, and striatum of the rat's brain against sodium nitroprusside-induced cellular death (Colle et al. 2012b). Possible mechanisms of protective action included its scavenger activities against reactive oxygen species (ROS) and reactive nitrogen species (RNS), which were attributed to the presence of phenolic compounds in the extract.

Anticancer Activity

A nondialyzable hot water dandelion extract (Tof-CFr) was found to have antitumour activity (Baba et al. 1981). The extract showed an antitumour effect in the allogeneic tumour system of ddY-Ehrlich and the syngeneic C3h/He-Mm46 with intraperitoneal injection. The extract showed cytolytic activation of macrophages in

antibody-dependent macrophage-mediated cytotoxicity and enhancement of antitumour delayed hypersensitivity reaction in C3H/He-Mm46 syngeneic and ddY-Ehrlich allogeneic tumour systems.

Studies showed that *Taraxacum officinale* decreased human hepatoma Hep G2 cell viability by 26 % and significantly increased the tumour necrosis factor (TNF)- α and interleukin (IL)-1 α production and strongly induced apoptosis of Hep G2 cells (Koo et al. 2004). Increased amounts of TNF- α and IL-1 α contributed to dandelion-induced apoptosis. Recent evidence showed that *T. officinale* has anticarcinogenic activity. Crude extract of dandelion leaf decreased the growth of MCF-7/AZ breast cancer cells, whereas the aqueous extracts of dandelion flower extract and root extract had no effect on the growth of either cell line (Sigstedt et al. 2008). Furthermore, the root extract was found to block invasion of MCF-7/AZ breast cancer cells, while the leaf extract blocked the invasion of LNCaP prostate cancer cells into collagen type I. In a recent study, the aqueous dandelion root extract effectively induced apoptosis in human leukaemia cell lines in a dose- and time-dependent fashion; the apoptosis was found to be mediated by caspase activation (Ovadjie et al. 2011). Interestingly, noncancerous peripheral blood mononuclear cells (PBMCs) exposed to the root extract under the same treatment conditions as leukaemia cells were not significantly affected. Lupane triterpenoids isolated from the roots, 18 α ,19 α -epoxy-21 β -hydroxylupan-3-one, and officinatriene exhibited moderate cytotoxic activities against murine leukaemia lymphocyte L1210 cell line (IC₅₀ 10.5 and 10.1 μ M) (Saeki et al. 2013).

Antiviral Activity

Aqueous dandelion extract exhibited potent activity against HIV-1 RT and inhibited both the HIV-1 vector and the hybrid-MoMuLV/MoMuSV retrovirus replication in-vitro (Han et al. 2011). Dandelion extracts may have potential application in the development of an antiretroviral therapy with fewer side effects.

Antiinflammatory Activity

Methanol dandelion flower extract markedly inhibited 2-*O*-tetradecanoylphorbol-13-acetate (TPA)-induced ear oedema in mice (Yasukawa et al. 1998). Kim et al. (1999) demonstrated that stimulation of mouse peritoneal macrophages with *Taraxacum officinale* after the treatment of recombinant interferon- γ (rIFN- γ) resulted in increased nitric oxide (NO) synthesis. When *T. officinale* was used in combination with rIFN- γ , there was a marked synergistic induction of NO synthesis in a dose-dependent manner. They found that the capacity of *T. officinale* to increase NO production from rIFN- γ -primed mouse peritoneal macrophages was the result of *T. officinale*-induced tumour necrosis factor- α secretion. *Taraxacum officinale* was found to inhibit tumour necrosis factor- α production from rat astrocytes stimulated with lipopolysaccharide (LPS) by decreasing interleukin-1 production (Kim et al. 2000). The results suggested dandelion exhibited antiinflammatory activity in the central nervous system.

The methanol root extract of *Taraxacum officinale* was found to exhibit inhibitory activity on the formation of leukotriene B₄ from activated human neutrophils (Kashiwada et al. 2001). The active principles identified in the extract were sesquiterpene glucosides: 14-*O*- β -D-glucosyl-11,13-dihydro-taraxinic acid and 14-*O*- β -D-glucosyl-taraxinic acid. In the carrageenan-induced air pouch model, the ethanol dandelion plant extract inhibited production of exudate and significantly diminished nitric oxide (NO) and leucocyte levels in the exudates (Jeon et al. 2008). Suppressive effects of the extract on the production of NO and expression of inducible nitric oxide synthase (iNOS) and cyclooxygenase-2 (COX-2) in lipopolysaccharide (LPS)-stimulated macrophages were also observed. Dandelion polysaccharides attenuated CCl₄-induced hepatic damage in Sprague–Dawley rats by modulating inflammatory responses and ameliorating oxidative stress (Park et al. 2010). Pretreatment with dandelion polysaccharides markedly decreased serum aspartate aminotransferase (AST) and alanine aminotransferase (ALT)

activities as well as hepatic lesions and increased free radical scavenging activity, as exhibited by a lowered TBARS concentration. Pretreatment with dandelion polysaccharides also reversed other hepatitis-associated symptoms, including glutathione (GSH) depletion, inhibited antioxidative enzyme activities, upregulation of NF-kappaB and increased expression of its regulatory inflammatory mediators, such as inducible nitric oxide synthase (iNOS), cyclooxygenase (COX)-2, tumour necrosis factor (TNF)-alpha and interleukin (IL)-1beta.

In another study, the methanol dandelion leaf extract and its fractions inhibited LPS-induced production of NO, proinflammatory cytokines and PGE(2) in a dose-dependent manner in the mouse macrophage cell line, RAW 264.7 (Koh et al. 2010). The chloroform fraction significantly suppressed production of NO, PGE(2) and two proinflammatory cytokines (TNF-alpha and IL-1beta) in a dose-dependent manner with 50 % inhibitory concentration values of 66.51, 90.96, 114.76 and 171.06 µg/ml, respectively. The ethyl acetate fraction also inhibited production of the inflammatory molecules. The chloroform and ethyl acetate fractions reduced LPS-induced expressions of iNOS and COX-2 and activation of MAP kinases in a dose-dependent manner. Among the fractions of the methanol extract, the chloroform and ethyl acetate fractions exhibited the most effective antiinflammatory activities. The results showed that the antiinflammatory effects of dandelion leaves were probably due to downregulation of NO, PGE(2) and proinflammatory cytokines and reduced expressions of iNOS and COX-2 via inactivation of the MAP kinase signal pathway.

Both methanol and water dandelion extracts inhibited lipopolysaccharide (LPS)-stimulated iNOS gene expression and that of its transcription factor, NF-κB, in parallel with nitrite reduction in RAW 264.7 cells (Park et al. 2011b). Both extracts significantly reduced NO production with an IC₅₀ of 79.9 and 157.5 µg/ml, respectively, without cytotoxicity. Depleted glutathione (GSH) and antioxidative enzyme activities, including superoxide dismutase, catalase, GSH-peroxidase

and GSH-reductase, were restored by dandelion extracts. The methanol extract showed more potent antioxidative and antiinflammatory capacities than the water extract, which was attributable to its higher total phenol, luteolin and cichoric acid content. In another study, co-treatment with luteolin and cichoric acid (both from dandelion) synergistically reduced cellular concentrations of nitric oxide (NO) and prostaglandin E2 (PGE2) and also inhibited expression of inducible nitric oxide synthase (iNOS) and cyclooxygenase-2 (COX-2) in lipopolysaccharide (LPS)-stimulated RAW 264.7 cells (Park et al. 2011a). Furthermore, co-treatment reduced the levels of proinflammatory cytokines, tumour necrosis factor (TNF)-α and interleukin (IL)-1β. Both luteolin and cichoric acid suppressed oxidative stress, but they did not exhibit any synergistic activity. Luteolin and cichoric acid co-treatment inhibited phosphorylation of NF-κB and Akt but had no effect on extracellular signal-regulated kinase (ERK), c-Jun NH2-terminal kinase (JNK) and p38. This antiinflammatory signalling cascade coincided with that affected by luteolin treatment alone. The results suggested that luteolin played a central role in ameliorating LPS-induced inflammatory cascades via inactivation of the NF-κB and Akt pathways and that cichoric acid strengthened the antiinflammatory activity of luteolin through NF-κB attenuation. In another study, pretreatment with taraxasterol (isolated from *T. officinale*) inhibited NO of prostaglandin E(2) (PGE(2)), tumour necrosis factor-α, interleukin IL-1β and IL-6 production in LPS-induced RAW 264.7 macrophages in a dose-dependent manner (Zhang et al. 2012). Further studies revealed that taraxasterol prevented the LPS-induced NF-κB translocation from cytoplasm into the nucleus. The results suggested taraxasterol to have antiinflammatory effect by blocking NF-κB pathway.

Hepatoprotective Activity

Carbon tetrachloride treatment decreased superoxide dismutase (SOD), catalase, glutathione

and peroxidase and increased lipid peroxidation in rats; in contrast, pretreatment of rats with 100 mg/kg (p.o.) of dandelion root hydroalcoholic extract improved the SOD, catalase, glutathione and peroxidase levels significantly and reduced lipid peroxidation (Sumanth and Rana 2006). The results suggested hydroalcoholic extract from the dandelion root possessed antioxidant activity, confirming the traditional use of the plant in treatment of liver disorders.

Studies by Colle et al. (2012a) markedly demonstrated the hepatoprotective effect of *T. officinale* leaf extract against the toxicity induced by acetaminophen. *T. officinale* decreased thiobarbituric acid-reactive substance levels induced by 200 mg/kg acetaminophen (p.o.), as well as prevent the decrease in sulphhydryl levels caused by acetaminophen treatment. Additionally, histopathological alterations, as well as the increased levels of serum aspartate and alanine aminotransferases caused by acetaminophen, were prevented by *T. officinale* (0.1 and 0.5 mg/ml). Further, dandelion leaf extract also demonstrated antioxidant activity in-vitro, as well as scavenger activity against DPPH and nitric oxide radicals. The possible mechanisms for its hepatoprotective effect may involve its scavenger activities against ROS and reactive nitrogen species, attributable to the presence of phenolic compounds in the extract.

Animal studies showed that the water ethanol dandelion root extract had therapeutic effect on CCl₄-induced liver fibrosis (Domitrović et al. 2010). The extract successfully decreased hepatic fibrinous deposits, restored histological architecture and modulated the expression of glial fibrillary acidic protein (GFAP) and alpha-smooth muscle actin (α -SMA). Concomitantly, metallothionein I/II expression increased in the extract-treated mice. Similarly, Mahesh et al. (2010) found that posttreatment of ethanol dandelion root extract and sesquiterpene lactones enriched fraction protected against CCl₄-induced hepatotoxicity in mice. Their results indicated that sesquiterpene lactones had a protective effect against acute hepatotoxicity induced by the administration of CCl₄ in mice. In another study, mice,

which received hot water dandelion root extract (1 g/kg bw/day) with ethanol, revealed complete prevention of alcohol-induced hepatotoxicity as evidenced by the significant reductions of serum aspartate aminotransferase, alanine aminotransferase, alkaline phosphatase and lactate dehydrogenase activities compared to ethanol-alone-administered mice (You et al. 2010). Dandelion extract-treated mice exhibited significant increases in hepatic antioxidant activities, including catalase, glutathione S-transferase, glutathione peroxidase, glutathione reductase and glutathione. Further, the amelioration of malondialdehyde levels indicated dandelion extract protective effects against liver damage mediated by alcohol in-vivo. The results suggested that the aqueous extract of *T. officinale* root exerted protective action against alcohol-induced toxicity in the liver by elevating antioxidative potentials and decreasing lipid peroxidation.

The HV-P411 complex, an herbal extract mixture from the seeds of *Vitis vinifera*, *Schisandra chinensis* and *Taraxacum officinale* elicited protective effects against D-galactosamine (D-GalN)-induced hepatitis in rats when orally administered 48, 24 and 2 hours before and 6 hours after D-GalN injection (Kang et al. 2012). Increases in serum aminotransferase activity and lipid peroxidation and a decrease in hepatic glutathione content were attenuated by the HV-P411 complex 24 hours after D-GalN treatment. The HV-P411 complex attenuated the increases in serum tumour necrosis factor- α , interleukin (IL)-6 level and cyclooxygenase-2 protein production and their mRNA expressions, while increases in serum interleukin IL-10 level and heme oxygenase-1 protein production and their mRNA expressions were augmented by the HV-P411 complex. The increased translocation of nuclear factor- κ B and c-Jun phosphorylation were attenuated by treatment with the HV-P411 complex.

Diuretic Activity

An animal study found that at high doses (2 g/kg body weight), dandelion leaves possessed diuretic

effects comparable to the prescription diuretic furosemide (Rácz-Kotilla et al. 1974). They concluded that dandelion contained three times the amount of potassium in other botanical diuretics and provided more potassium than that lost from diuresis induced by ingesting dandelion. Thus, dandelion could offer a therapeutically significant potassium contribution by replacing the potassium loss induced by most diuretics.

In a pilot study of 17 human volunteers, hydro-ethanol extract of dandelion leaves showed promise as a diuretic (Clare et al. 2009). There was a significant increase in the frequency of urination in the 5 hours period after the first dose. There was also a significant increase in the excretion ratio in the 5 hours period after the second dose of extract.

Adaptogenic Activity

Studies showed that *Taraxacum officinale* extract had an anti-physical fatigue effect in mice (Zhang and Chen 2011). After 6 weeks of supplementation, the extract enhanced the maximum swimming capacity of mice, effectively delayed the lowering of glucose in the blood and prevented the increase in lactate and triglyceride concentrations. In the forced swimming test, immobility time was significantly decreased on the tenth day in the group of mice treated with dandelion extract (100 mg/kg) (Lee et al. 2012). The level of lactic dehydrogenase, which is an accurate indicator of muscle damage, tended to decline after dandelion administration (10 and 100 mg/kg). When dandelion extract (100 mg/kg) was orally administered to mice, blood urea nitrogen levels decreased significantly. When dandelion extract was used in combination with recombinant interferon-gamma (rIFN- γ), a noticeable cooperative induction of tumour necrosis factor-alpha (TNF- α), interleukin (IL)-12p70 and IL-10 production was observed. Further, in peritoneal macrophages, rIFN- γ plus dandelion treatment significantly increased the production of NO through inducible nitric oxide synthase (iNOS) induction. The data suggested that dandelion improved fatigue-related indicators and immunological parameters in mice.

Probiotic Activity

The infusion of dandelion root (*Taraxacum officinale*) stimulated in-vitro the growth of 14 strains of bifidobacteria (Trojanová et al. 2004). The utilization of oligofructans, glucose, fructose and total saccharides was determined by enzymatic and phenol-sulphuric methods. Dandelion oligofructans were important source of carbon and energy for bifidobacteria tested. Bifidobacteria aid in digestion, are associated with a lower incidence of allergies and also prevent some forms of tumour growth and are being used as probiotics.

Antimicrobial Activity

Three peptides, ToAMP1, ToAMP2 and ToAMP3, purified from dandelion flowers were shown to display high antimicrobial activity both against fungal and bacterial pathogens (Astafieva et al. 2012).

Anti-obesity/Antihyperlipidemic Activity

The 95 % ethanol extract of *T. officinale* and Orlistat (an anti-obesity agent) inhibited porcine pancreatic lipase activity by 86.3 and 95.7 % at a concentration of 250 μ g/ml, respectively, in-vitro (Zhang et al. 2008). Dandelion extract showed dose-dependent inhibition with the IC₅₀ of 78.2 μ g/ml. A single oral dose of the ethanol extract to mice significantly inhibited increases in plasma triglyceride levels at 90 and 180 minutes and reduced incremental areas under the response curves of plasma triglyceride response curve. The results indicated that *T. officinale* exhibited inhibitory activities against pancreatic lipase in-vitro and in-vivo. Diet supplementation with dandelion root and leaf root positively changed plasma antioxidant enzyme activities and lipid profiles in cholesterol-fed rabbits and thus may have potential hypolipidaemic and antioxidant effects (Choi et al. 2010). The authors concluded that dandelion root and leaf could protect

against oxidative stress-linked atherosclerosis and decrease the atherogenic index.

In a randomized double-blind, crossover study with no washout period involving men with hypercholesterolaemia, dietary inulin supplementation was found to improve blood lipid profiles and altered the colonic environment in a beneficial manner (Causey et al. 2000).

Pulmonary Protective Activity

Studies showed that *Taraxacum officinale* protected against lipopolysaccharide (LPS)-induced acute lung injury in mice (Liu et al. 2010). Dandelion treatment decreased the lung W/D ratio, protein concentration and the number of neutrophils in the bronchoalveolar lavage fluid (BALF) at 24 hours after LPS challenge. Dandelion also inhibited the production of inflammatory cytokines TNF-alpha and IL-6 in the BALF at 6 hours after LPS challenge in a dose-dependent manner. Further, histopathological examination indicated that dandelion attenuated tissue injury of the lungs in LPS-induced acute lung injury.

Antinociceptive Activity

The ethanol dandelion plant extract also possessed an inhibitory effect on acetic acid-induced vascular permeability and caused a dose-dependent inhibition on acetic acid-induced abdominal writhing in mice (Jeon et al. 2008).

Pancreas Protective Activity

Studies showed that dandelion extract had a protective effect on cholecystokinin (CCK) octapeptide-induced acute pancreatitis in rats (Seo et al. 2005). Dandelion significantly decreased the pancreatic weight/body weight ratio in cholecystokinin octapeptide-induced acute pancreatitis. It also increased the pancreatic levels of HSP60 and HSP72. Further, the secretion of interleukin 6 and TNF-alpha decreased in the animals treated with dandelion extract.

Anticolitic Activity

Taraxacum officinale in a herbal combination with *Hypericum perforatum*, *Melissa officinalis*, *Calendula officinalis* and *Foeniculum vulgare* was found effective in treating chronic colitis in 24 human patients (Chakürski et al. 1981). As a result from the treatment, the spontaneous and palpable pains along the large intestine disappeared in 95.83 % of the patients by the 15th day of their admission to the clinic. Defecation became daily in the patients with obstipation syndrome and in patients with diarrhoea syndrome.

Antiangiogenic Activity

The ethanol dandelion plant extract showed an antiangiogenic activity in the chicken chorioallantoic (CAM) assay (Jeon et al. 2008). Among the various fractions, the n-butanol fraction (BuOH) was identified to be most effective in the CAM assay.

Neuroprotective Activity

Studies showed that spirulina (*Arthrospira platensis*) or dandelion-enriched diet of female rats (mothers) alleviated lead acetate-induced damages in brain and cerebellum of newborn rats by reducing lead-induced oxidative stress and related cerebellum tissue damages (decrease in weight and protein content) (Gargouri et al. 2012).

Immunomodulatory Activity

Studies in mice showed that the dandelion hydroalcoholic extract had immunomodulatory property (Modaresi and Resalatpour 2012). At all three doses of 50, 100 and 200 mg/kg, the number of RBC and the rate of heart beat were significantly increased, and at 200 mg/kg dose, WBC number was significantly increased to achieve normal body balance. All three doses of dandelion increased lymphocyte numbers significantly compared with controls.

Gastroprokinetic Activity

N-butanol fraction of dandelion ethanol extract appeared to be a promising prokinetic agent in mice (Jin et al. 2011). Dandelion fraction-induced increase in the contraction of fundus and antrum contributed to an increase in the intragastric pressure. Dandelion fraction-induced decrease in the motility of pyloric sphincter contributed to a decrease in the resistance of food from the stomach to the small intestine. The acceleration of gastric emptying by the fraction was postulated to be exerted through cholinergic stimulation.

Hypoglycaemic Activity

Dandelion root extract showed hypoglycaemic activity in normoglycaemic but not in alloxan-treated hyperglycaemic (diabetic) rabbits (Akhtar et al. 1985). Studies in Croatia reported that an antidiabetic herbal preparation (Patent No. P-9801091, Zagreb) comprising leaf of *Vaccinium myrtillus*, dandelion root (*Taraxacum officinale*), chicory root (*Cichorium intybus*), juniper fruit (*Juniperus communis*), centaury plant (*Centaureum umbellatum*), beans (*Phaseolus vulgaris*), yarrow herb (*Achillea millefolium*), black mulberry leaf (*Morus nigra*), valerian root (*Valeriana officinalis*) and nettle plant and root (*Urtica dioica*), exhibited hypoglycaemic activity (Petlevski et al. 2001). The herbal preparation significantly decreased the level of glucose and fructosamine in alloxan-induced nonobese diabetic mice. In-vitro studies showed that ethanol extract of *Taraxacum officinale* at 40 µg/ml exerted insulin secretagogue activity in pancreatic insulinoma INS-1 cells, suggesting its potential as a natural resource for antidiabetic compound (Hussain et al. 2004). In contrast, a study in Europe found that 28-day treatment of normal and streptozotocin-induced diabetic mice with dandelion preparation did not affect the parameters of glucose homeostasis (basal plasma glucose and insulin, glucose tolerance, insulin-induced hypoglycaemia and glycated haemoglobin) in normal mice and did not significantly affect glucose homeostasis studied (basal glucose

and insulin, insulin-induced hypoglycaemia, glycated haemoglobin and pancreatic insulin concentration) in streptozotocin-induced diabetic mice (Swanston-Flatt et al. 1998).

Goksu et al. (2010) reported the first case of hypoglycaemia caused by ingestion of dandelion. Kango (2008) found that the dandelion tap root extract induced endoinulinase synthesis in *Aspergillus niger* NK-126 and could be utilized as a potential substrate for inulinase production. This enzyme catalyzes the conversion of inulin to fructose.

Antiuro lithiatic activity

T. officinale was one of seven plants tested that exhibited antiuro lithiatic activity in female Wistar rats (Grases et al. 1994). It exerted beneficial effects on some urolithiasis risk factors (citraturia, calciuria, phosphaturia, pH and diuresis) evaluated, attributable to some disinfectant action and to the presence of saponins.

Bile Secretion/Digestive Stimulant Activities

Sesquiterpene lactones were found to be the bitter principles in dandelion leaves and roots which stimulate digestion and act as mild laxatives (Kuusi et al. 1985). Oral administration of extracts from the roots of *Taraxacum officinale* was found to act as a cholagogue, increasing the flow of bile (Vogel 1977).

Fertility and Antifertility Activity

Studies showed that oral intake of dandelion T-1 extract for 6 weeks upregulated oestrogen receptors (ERalpha and ERbeta), progesterone receptor (PR) and follicle-stimulating hormone receptor (FSHR) expression in mice, suggesting the potential application of dandelion extract in the clinical treatment of reproductive hormone-related disturbances (Zhi et al. 2007). In a placebo-controlled, parallel-arm, pilot study of

40 healthy premenopausal women, over five menstrual cycles, Greenlee et al. (2007) compared the effects of a naturopathic botanical and dietary interventions on sex steroid hormone metabolism. The botanical supplement comprised *Curcuma longa*, *Cynara scolymus*, *Rosmarinus officinalis*, *Schisandra chinensis*, *T. officinale* and *Silybum marianum*, and the dietary interventions consisted of crucifers or dark leafy greens. During the early follicular phase, compared with placebo, the botanical supplement decreased androgens dehydroepiandrosterone (−13.2 %), dehydroepiandrosterone sulphate (−14.6 %) and androstenedione (−8.6 %) and the oestrogen estrone sulphate (−12.0 %) with no significant effects on levels of any other sex steroid hormones. When comparing dietary interventions with placebo, no statistically significant differences were observed.

Administration of aqueous dandelion extract at high (1/10 LD₅₀) and low (1/20 LD₅₀) doses to male rats resulted in a significant decrease in testis weight, sperm count, motility and normal morphology, pregnancy rate and diameter and wall thickness of seminiferous tubules (Tahtamouni et al. 2011). Also, distortion of morphology of the seminiferous tubules and arrest in spermatogenesis was observed in the extract-treated group. Further, the percentage of sperm with damaged chromatin integrity was significantly higher in the two extract-treated groups. They concluded that the aqueous extract of *Taraxacum officinale* acted as an antifertility agent rather than a fertility booster as prescribed by Jordanian herbalists.

Allergy Problems

Compositae dermatitis was reported in a 9-year-old boy with a strong personal and family history of atopy (Guin and Skidmore 1987). Positive patch test reactions were 2+ for dandelion (*Taraxacum officinale*), false ragweed (*Ambrosia acanthicarpa*), giant ragweed (*Ambrosia trifida*), short ragweed (*Ambrosia artemisiifolia*), sagebrush (*Artemisia tridentata*), wild feverfew (*Parthenium hysterophorus*), yarrow (*Achillea millefolium*) and tansy (*Tanacetum vulgare*). The eruption resembled atopic dermatitis morphologically but
